Sir T. Lauder Dick ascribes this effect to a grand system of displacement of the crust of the globe, whereby the Great Glen of Scotland was produced; that glen is a symmetrical axis of displacement, of which we can hardly know the true geological date, but it is clear that so remarkable a feature in the geology and geography of Scotland as this Great Glen cannot be neglected in speculations on the antient lakes of Lochaber, and Sir T. L. Dick's hypothesis acquires no little plausibility from the use he has made of this great line of subterranean movement. Dr. MacCulloch, instead of these originally separate lakes, of which he cannot see the probable barriers, supposes one continuous lake in the valleys of the Roy, the Spean, the Gluoy, and the Lochy, and imagines barriers on the way to the sea, in the valleys of the Spey and the Lochy, and on the line of the Great Glen.

Struck with the difficulties under which both these hypotheses labour, in regard to the antient existence and removal of barriers in such improbable situations, Mr. C. Darwin has proposed a new view of the case, in conformity with the opinion of Mr. Lyell (*Princip. of Geology*, book iv., chap. 10), regarding the parallel roads of Coquimbo in Chili, described by Captain Hall. Mr. Lyell's speculation on the phenomena of Coquimbo is, that 'the three parallel roads were formed by the waves of the Pacific, and not by the waters of a lake; in other words, they bear testimony to the successive rise of the land, not to the repeated fall of the waters of the lake.'

From a series of appearances below the lowest shelf of Glen Roy, continued into Glen Spean,—such as the nature and distribution of detritus, the form and position of many short terraces, some related to the shelf or antient beach, others unconnected with the actions of the streams now running—Mr. Darwin concludes, apparently with reason, that every appearance in the sides of Glen Roy and Glen Spean, *below the lowest shelf*, will be explained on the supposition of a gradually subsiding sheet of water which received detritus from lateral streamlets. By observations of accumulated sand and pebbles in other valleys, as the sides of Loch Ness, Loch Dochart, &c., Mr. Darwin endeavours to extend this inference to a large portion of the Highland valleys, where no horizontal shelves make it a matter of certainty. Having rejected the hypotheses of separate and connected fresh-water lakes, on account of the difficulties attending them, which even in a single case are great (but if extended to many of the Highland valleys, insurmountable) Mr. Darwin adopts the alternative, that it was the sea in the form of narrow arms or lochs, such as those now deeply penetrating the western coast, which once entered and gradually retired from these several valleys.

That there has been a change of level between the land and sea in Scotland, to the extent of several hundred feet, is proved by Mr. Smith's and Mr. Prestrich's observations at Banff and near Glasgow and other places; and, thus fortified, Mr. Darwin traces in hypothesis the effect of an elevation of the land equably or by intermitting effects, showing that by this means the main phenomena of the Lochaber valleys would certainly be occasioned.

Objections to this speculation easily arise.—Why, for example, are shelves, the marks of intermission in the elevating forces which affected a large area with extraordinary equality, confined to a few valleys? Why, after encircling in complete belts the upper ends of the valleys, do they cease toward the outlets? Why has Glen Roy three shelves, and the neighbouring Glen Gluoy but one, and that at a different level from any in Glen Roy? Why, if the sea for *so long a time* laved the mountain sides, are no marine shells found except at comparatively small elevations?

Mr. Darwin answers to these objections: 1, that the conservation and even the original formation of *beaches* (for such the shelves certainly are) might rather be the exception than the rule, requiring particular slopes, loose materials, and freedom from erosive currents; 2, that the difference of level between the Glen Gluoy shelf and the highest in Glen Roy may be explained as an effect of unequal tidal oscillation; 3, that instances of the absence of marine shells from the upper parts of marine deposits occur in Sweden, Scotland, and elsewhere.

Such are the speculations to which the parallel roads of Glen Roy have given rise. The progress of modern geology has revealed so many proofs of the instability of the level of land and sea, and so many examples in which this change of level has been occasioned by a real displacement of land, that it is probable Mr. Darwin's explanations, drawn from the most general consideration, will be preferred to those which are more obviously suggested by the features of any one of the terraced glens.

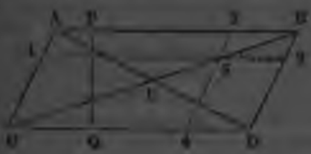
Mr. Darwin's hypothesis has the further advantage of offering a plausible explanation of the occurrence of erratic boulders of granite, which in places encumber the lines of beach. These may be easily supposed to have floated on icebergs from even distant points, and to have quietly rested on the beaches, and it is certainly difficult to account otherwise for the phenomenon. Enough has been said to show within how small a compass the question as to the origin of the parallel roads of Lochaber has been brought. In order to complete the solution of the problem, it is desirable to repeat very carefully the levelling operations which have been attempted by Sir T. Lauder Dick and Dr. MacCulloch.

It appears almost certain that the 'line' in Glen Gluoy is exactly level with the summit of drainage between it and Glen Roy; the shelf of Kilfinnin and the upper shelf in Glen Roy in like manner are exactly level with the watersheds dividing them from neighbouring valleys. The connection of these facts with Sir T. Lauder Dick's hypothesis of subsiding lakes in the valleys appears more evident than with Mr. Darwin's speculation of rising land.

Very exact levelling operations have proved that the real level of equilibrium of the sea is the *half tide line* (See *British Association Report for* 1837-8), but beaches are commonly found at the high-water level, which varies so much from the form and direction of channel and other courses, that *perfect horizontality* in the whole extent of the lower shelf of Glen Roy, Glen Spean, and Glen Treig would be only a dubious argument in favour of its marine origin. To determine the real differences of level between the highest beach in Glen Roy and the shelves of Glen Gluoy and Kilfinnin is equally important, since possibly these differences may not be at all greater than what are known to take place in some neighbouring arms of the sea which admit the tide unequally. Finally, we ought to know the true form of the imaginary surface to which the roads are parallel. They may lie nearly and yet not accurately in horizontal planes; if a real deviation from the horizon were found on comparing distant points, this might be symmetrical to a synclinal or anticlinal axis, and however small such *regular* deviation, it would have the same kind of interest in geology as the discovery of a true axis of movement in Scandinavia or Dorsetshire. Adequate observations on this subject may be difficult in Lochaber, of patience, has overcome all obstacles of mere levelling in the beautiful operations executed by Mr. Bunt, on a line chosen by Mr. Whewell, between Bristol and Axmouth; and the results which, some years or centuries hence, may seem to emerge from that splendid work, might perhaps be even now anticipated by a summer's work of the ordnance surveyors in the valleys connected with Glen Roy.

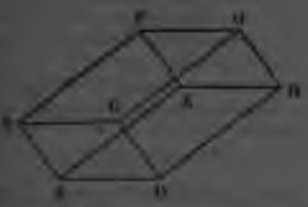
(MacCulloch, in *Geol. Trans.*, vol. iv.; Sir T. Lauder Dick, in *Trans. of Roy. Soc. of Edinb.*, vol. ix.; Darwin, in *Phil. Trans. for* 1839.)

PARALLELOGRAM (παραλληλό-γραμμον, parallel-lined figure) is the mathematical term for a four-sided figure of which the opposite sides are parallel. Such a figure may be obtained from *any* four-sided figure by bisecting the four sides and joining the adjacent bisecting points. When all the angles of a parallelogram are equal, they are therefore right angles, and the figure is called a RECTANGLE. When the sides are also equal, the figure is a SQUARE; matters of more historical interest are connected with either of these terms than with the generic term parallelogram. Referring therefore to those articles, we shall here give the principal properties of parallelograms in general.



1. The opposite sides are equal, as A C and B D.
2. The opposite angles are equal, as A C D and A B D, and adjacent angles (as those at A and B) are together equal to two right angles.
3. The diagonals (A D and B C) bisect one another.
4. The sum of the squares on the four sides is equal to the sum of the squares on the diagonals.
5. The area of a parallelogram depends only on the side (as C D) and the perpendicular distance (P Q) between that and the opposite side; so that parallelograms on equal bases and between the same parallels are equal.
6. If the point (5) be taken on a diagonal (C B) and made the vertex of a pair of parallelograms (A125 and D453) lying in the equal triangular halves of the parallelogram, these parallelograms will be equal to one another in area.

PARALLELOPIPED (παραλληλ-επίπεδον, parallel-plane solid), more correctly written *parallelepiped*, is the name given to a solid contained by six parallelograms, which are equal and parallel, two and two. It is in fact a quadrangular prism.



When all the parallelograms are rectangles, we have one of the figures to which our eyes are most accustomed, as in the cases of a die, a box, a plank, a room, &c. &c. Persons not acquainted with mathematics would hardly believe that English mathematicians seldom express this most simple and elementary of all solids in less than ten syllables, as follows:

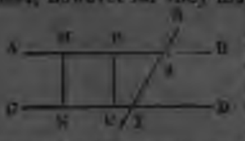
rect-ang-ul-ar par-all-el-o-pi-ped.

A more simple term might easily be obtained, and one perfectly consistent with analogy, namely, *right solid*. Thus a right line might be conceived as generated by the most simple motion of a point; a right surface (or rectangle) by the most simple motion of a right line; and a right solid (or rectangular parallelopiped) by the most simple motion of a right surface. We shall consider the properties of a right solid in the article RECTANGLE.

When the adjacent rectangles of a right solid are squares, the solid is a CUBE, for which fortunately there is a shorter term than equilateral rectangular parallelopiped.

The number of solid units in a parallelopiped is found by multiplying the number of square units in either base by the number of linear units in the perpendicular distance between that base and the opposite one. The diagonals A G, B H, C E, D F, meet in the same point, which bisects them all, and the sum of their squares is equal to the sum of the squares of all the twelve sides of the solid.

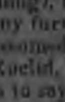
PARALLELS (παράλληλαι, by the side of each other), the name given by the Greek geometers to lines in the same plane having that relation of situation of which it is one of the most obvious properties that such lines never meet, however far they may be produced or lengthened.



If we examine the properties of lines experimentally, it will be easy to satisfy ourselves of the existence of such pairs as A B, C D, which neither diverge nor converge, and to which common perpendiculars, such as M N and P Q, all of the same length, can be drawn through any point of either. Moreover the angles R S B and R T D, made by the same line with both, will be found to be the same. If then we take the notion of permanence of direction, which always accompanies that of straightness [DIRECTION], and also the notion of differing directions, which is suggested by two lines which make an angle, we may readily see that the relation of situation which, adopting Euclid's term, may be called *parallelism*, is really that which would be also conveyed by the words sameness of direction; so that if two lines A and B be parallel, A may be substituted for B or B for A, in any proposition which involves relations of direction only, without affecting the truth of that proposition, if true, or its falsehood, if false.

Geometry, as every beginner knows, depends upon a small number of self-evident truths, or rather of propositions the truth of which (*with one exception*) is so soon and so easily perceived, that no one doubts of them when stated with ordinary attention to clearness of expression. The exception alluded to appears for the first time in Euclid, and has been the occasion of a controversy which has lasted from his time to the present.

It will be remarked that the definition of parallel lines is purely negative; it describes what they are not, not what they are: if lines which meet be called intersectors, parallels are non-intersectors. Those who would found geometry upon definitions entirely, may think that the difficulty of the theory of parallels arises from insufficient definition: but those who believe it to be deducible from real and positive conceptions, having nothing arbitrary about them, must suspect that, in this purely negative definition of parallels, we have not sufficiently described that very obvious relation of position which distinguishes parallelism from convergence, however short the lines we image to ourselves, or however little we think of what will take place if they are produced. Euclid, proceeding upon axioms the admission of which is not considered to be a question connected with the present difficulty, establishes the following proposition:—If the two lines S B and T D make the angles P S T and S T D equal, or R S B and S T D equal, or B S T and S T D together equal to two right angles (all which amount to the same thing), then S B and T D are non-intersectors. But before any further step can be made, it must either be proved or assumed that in every other case they are intersectors, and Euclid, being unable to prove it, assumes it directly. That is to say, he requires it to be granted that if B S T and S T D be together less than two right angles, S B and T D will meet, if produced, and on that side on which they make with S T the angles less than two right angles. The last clause is not a necessary part of the axiom, since it can be shown, independently of the present theory, that two lines which meet must make angles together less than two right angles with any line which cuts them internally.



Euclid obviously puts the *whole* difficulty into an assumption; which, though the most direct course, is not that which is best calculated to give the highest degree of evidence to geometrical truths. For it is a more obvious proposition that two lines which intersect one another cannot *both* be parallel to a third line, and this being granted, Euclid's axiom readily follows. If it should be objected that this is merely Euclid's axiom in another form, it is replied that the form is a more easy one, and therefore preferable: just as it would be wiser to assume 'Every A is B and every B is A,' than the identical but more complicated proposition 'Every A is B, and everything which is not A is not B.'

It is known then that the difficulty is entirely removed if we grant that 'two lines which intersect are not both parallel to any third line,' or, which is the same thing, that 'through a given point not more than one line can be drawn parallel to a given line.' The theory of Euclid being thus improved as far as it is capable of being done by a mere difference of statement, it remains to ask, 1, Whether assumption can be dispensed with altogether, and a direct proof of Euclid's axiom, or something equivalent to it, given? 2, If the preceding be answered in the negative, can any more simple assumption be made the foundation of the theory?

The attempts to answer one or the other question in the affirmative have been very numerous, and have (without any exception but one in which new axioms of another sort are introduced) tacitly contained the defect which their authors were desirous of avoiding. The author of 'Geometry without Axioms' has collected and commented on thirty instances, of which we here make a brief abstract, adding one or two more.

1, The axiom of Euclid in question. 2, Ptolemy; his proof assumes the symmetricality of parallel lines on one side, and the other of any line which cuts both. 3, Proclus assumes that intersectors diverge infinitely from the point of intersection, and that parallels do not. 4, Clavius assumes that a line which is everywhere equidistant from a straight line, is itself straight. 5 and 6, Two demonstrations of Dr. Thomas Oliver (1604) assume Clavius's axiom. 7, Wolf, Boscovich, T. Simpson (in the first edition of his 'Elements'), and Bonnycastle, define parallel lines as those which always preserve the same distance, which is Clavius's axiom in the disguise of a definition. 8, D'Alembert would define parallels as lines, one of which has two points equidistant from the other, but acknowledged that he could not complete the proof of the axiom of Clavius. 9, T. Simpson ('Elements,' 2nd edition) proposed to assume that two lines, one of which has two points unequally distant from the other, must meet. 10, Robert Simpson proposed to assume that a straight line cannot first approach to and then recede from another, without cutting it. 11, Varignon, Bezout, &c. would define parallels as lines which make the same angle with a third line: if *a* third line mean one third line, the difficulty remains just as before; if *any* third line, the difficulty is tacitly removed by an assumption. 12, Ludlam, Playfair, &c. recommend the axiom which we have also recommended, namely, that two intersecting straight lines cannot be both parallel to a third. 13, Leslie proposes to attain the same axiom in a sort of experimental manner, by making a line revolve about a point. 14, Playfair (in his Notes) proposes to assume that a straight line which turns completely round, and thus regains its first position, must turn through four right angles, whether it constantly revolves about one point, or whether the pivot of revolution changes. 15 and 16, Franceschini (1787) proposes to assume that the projections of a straight line on a line making an acute angle with it, increase without limit with the projected line. 17, Some have proposed to define parallels as 'lines having the same direction,' assuming it to be obviously contained in the conception of direction, that two similar directions make the same angle with any other direction. 18, Mr. Exley (1818) proposes to assume that if four equal straight lines, each at right angles to the preceding, do not meet and enclose a space, a fifth such line would do so. 19, Dr. Creswell proposes to assume that through any point within an angle less than two right angles, a straight line may be supposed to be drawn cutting the two straight lines which contain the angle. 20, Professor Thompson makes it an axiom that 'if a triangle be moved along a plane, so that its base may always be on the same straight line, its vertex describes a straight line equal to that described by either extremity of the base. 21, M. Legendre (in the earlier editions of his 'Elements') makes a direct appeal to the senses. 22, In the seventh edition he assumes (as in instance 15) that a magnitude increases without limit, where perpetual increase is all that is demonstrable. 23, In the twelfth edition he fairly brings the disputed proposition to rest upon the axiom, that if two angles of a triangle diminish without limit, the third (whatever the base may be) approaches without limit to two right angles, a proposition not admissible when, as in M. Legendre's final construction, the base at the same time increases without limit. 24, In a note to the same edition, he demands as an axiom that no straight line can be entirely included between two straight lines which make an angle less than two right angles, which may easily be shown to be nothing more or less than Euclid's axiom. 25, He attempts a proof of the last, which fails. 26, M. Legendre's analytical proof, which we shall presently examine. 27, M. Lacroix would confine the assumption of Euclid to the case in which one of the internal angles is a right angle and the other less. 28, M. Bertrand extends the use of the term equality; we shall afterwards examine his proof. 29, Mr. Ivory assumes a right to construct a series of triangles in a manner which cannot be certainly done unless an assumption as difficult as in (20) be made: and 30, Professor Young makes a modification of the preceding, which does not remove the difficulty.

For further information we may refer to the work from which the preceding abstract is taken. The author of it proposes his own system, the latent assumption of which is, that if equal straight lines make an angle, and other straight lines equal to them be attached to their extremities at the same angle, the remaining extremities of the second pair of straight lines will *not** always meet.

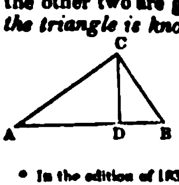
The author of 'Geometry without Axioms,' Colonel Perronet Thompson, whose erudition on this subject would alone entitle any attempt of his to attention, has, while this article was in the press, published a new pamphlet on the subject, in which he proposes to deduce the properties of the equiangular spiral, and to make them the foundation of a proof of Euclid's axiom. Not having been able to give this pamphlet sufficient attention, we can only here say, that it assumes the doctrine of limits, and the theorem that velocities (in one case at least) are to one another in the limiting ratio of spaces described in the same times. Whatever we may, on closer examination, think of this method as evidence for producing conviction, we cannot take such an assumption as removing the geometrical difficulty, since, by the introduction of a totally new line, it leaps the conventional boundaries of geometry [GEOMETRICAL]: to say nothing of the question which may fairly arise, as to whether the axioms of the theory of limits are not as difficult as that of Euclid.

Two proofs have been referred to as requiring further explanation: those of MM. Legendre and Bertrand. We take them successively.

The first assumes all that knowledge which is derived from algebra and the theory of algebraical operations. We premise that the theory of parallels may be strictly deduced, though not without some trouble, if it can previously be shown that the three angles of a triangle are equal to two right angles. Let there be a triangle of which the base contains c linear units, and the opposite angle C angular units, the other angles containing A and B units. Then it can be easily shown that any other triangle which has the same base c and the same adjacent angles A and B must be in all respects equal to the first: that is, c, A, and B being the side and adjacent angles of a really existing triangle, C is given when c, A, and B are given. There must then be some analytical mode of expressing C in terms of c, A, and B, such as

$$C = \phi(c, A, B).$$

From such an equation, if it exist, c can be found in terms of A, B, and C, that is, the length of a straight line can be expressed by means of angles only. Now it is known that no equation can determine a magnitude by means of magnitudes no one of which is of the same kind with it; and the only way of avoiding this supposition is by supposing that c does not enter the equation at all, or that $C = \phi(A, B)$, so that the third angle of a triangle is given when the other two are given, whatever the side may be, *provided the triangle is known to exist*. Let there be a right angled triangle ACB, and let CD be perpendicular to AB; then the triangles ACB and ACD, have a common angle at A, and a right angle in each: consequently their third angles are equal, or AC



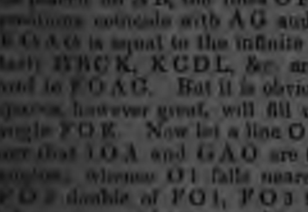
---

* In the edition of 1833, this assumption was explicitly made. A [illegible] the 'Journal of Education' (vol. vii, p. 105) having pointed this out, the [illegible] 'provided the straight lines do not meet' were added (in the edition [illegible]) [illegible] the enunciations of the leading propositions of the proof. This [illegible] moves the difficulty from the propositions themselves, but throws it upon [illegible] consequences; and the final result only remains proved, provided [illegible] do not always meet: that is, the proposition that they do not always meet [illegible] remains an axiom. The work is well worth the perusal of the student [illegible] we have no doubt whatever that in respect to the theory of parallels [illegible] amendment of Euclid.

= A B D. Similarly D C B = C A B; whence the angles at A and B are together equal to a right angle. And if the two acute angles of a right angled triangle be equal to one right angle, it is readily shown that all the three angles of any triangle are equal to two right angles.

It is not our intention to go fully into the objections which have been made to this proof, or to Legendre's answers; all which may be found in the notes to Dr. Brewster's translation of Legendre. It has the disadvantage of being founded upon a science which requires more and harder axioms than geometry itself, and of which the particular process employed, namely, inversion of a function, is in many cases full of unexplained difficulties; while it has the advantage of not appealing to any new notions of space. As an illustration of the connexion between algebra and geometry, it must always be valuable: but we suppose no one would think of making it the foundation of geometry. Some objectors imagined that Legendre would infer that a base with two adjacent angles together less than two right angles, must be the base of a triangle; or that because the formula applies wherever there is a triangle, that there must be a triangle wherever the formula applies. If this were the case, undoubtedly they were right in saying that Legendre did in fact assume Euclid's axiom: but if, as we apprehend, he would have applied the proposition thus proved of existing triangles, to the proof of Euclid's axiom, he should certainly have stated his intention more distinctly in his reply. It seems to us that he took it as admitted on all sides how to deduce Euclid's axiom, while his opponents imagined that he considered himself as having proved that axiom.

The proof of M. Bertrand is as follows:—Let it be granted that two spaces, *whether finite or infinite*, are equal,* when one can be placed upon the other so that any point whatsoever of either lies upon a point of the other: that is, let it be legitimate to say, of the word equal as thus used, that spaces which are equal to the same space are equal to one another. Granting this, it is easily shown—1, that the infinite spaces of equal angles are equal; 2, that of two angles, the infinite space contained in the greater is greater than the infinite space contained in the less.



Let there be two lines, O F, A G, making with O A internal angles F O A, G A O, equal to two right angles. Then O F and A G are parallel. Take A B, B C, C D, &c. each equal to O A, and make the angles H B C, K C D, L D E, &c. all equal to F O A or G A B. Let all lines with arrow-heads be produced without limit in the direction in which the arrow-head points. Then if O A be placed on A B, the lines O F and A G will in their new positions coincide with A G and B H, or the infinite space F O A G is equal to the infinite space G A B H: and similarly H B C K, K C D L, &c. are all equal to one another and to F O A G. But it is obvious that no number of these spaces, however great, will fill up the infinite space of the angle F O E. Now let a line O 1 be drawn in such a manner that 1 O A and G A O are together less than two right angles, whence O 1 falls nearer than O F to O E. Take F O 2 double of F O 1, F O 3 treble of F O 1 and so on: whence, since of two quantities which bear a ratio, the less may be multiplied so as to exceed the greater, some multiple of F O 1 must be greater than F O E, whence some multiple of the infinite space F O 1 is greater than the infinite space F O E. But no multiple of F O A G will be so great as F O E; whence the infinite space F O 1 must exceed the infinite space F O A G. Therefore O 1 produced must cut A G: for if not, the space F O 1 would be entirely contained in F O A G, and the former could not exceed the latter.

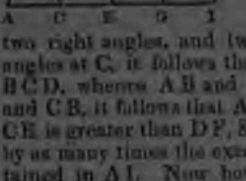
We have not noticed the numerous attempts at the solution of the difficulty which proceed by tacit assumption or illogical process, under the pretence of avoiding the axiom of Euclid, without substitution of any other. We shall conclude this article with an account of a result contained in a paper, by Legendre, in the 12th volume of the 'Memoirs of the Institute,' being his latest attempt at the solution of the problem. It is what he properly styles a geometrical translation of the analytical proof already noticed, and its chain of reasoning is contained in three propositions.

1. It is impossible that the sum of the angles of a triangle can in any case exceed two right angles.

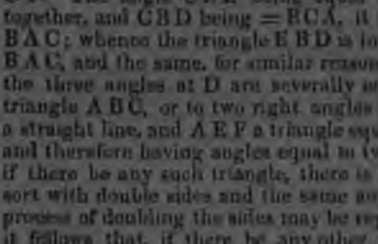
2. If there be any one triangle which has angles together equal to two right angles, the same must be true of all triangles.

3. If the angles of a triangle be not equal to two right angles, then angles alone may be made to determine a straight line.

1. If it be possible, let there be a triangle B A C having its angles together greater than two right angles. In A C produced take C E, E G, G I, each equal to A C, and make the angles D C E, F E G, &c. each equal to B A C, and let C D, E F, &c. be each equal to A B. Join B D, D F, &c., which are not known to be in the same straight line, though they are so. Then the triangles D C E, F E G, &c. are severally equal in all respects to B A C. And because the angles at A, B, C are together (by hyp.) greater than two right angles, and two of them are equal to two of the angles at C, it follows that the angle A B C is greater than B C D, whence A B and B C being severally equal to D C and C B, it follows that A C is greater than B D. Similarly C E is greater than D F, &c., whence A I exceeds B D F H K by as many times the excess of A C over B D as A C is contained in A I. Now however small this excess may be, it may be multiplied until the multiple exceeds twice A B, or A B and K I together. That is, A I, one side of a figure, may be made greater than A B, B D, D F . . . K I, the sum of all the other sides; which is absurd. Hence, it is not true that the angles of any triangle are together greater than two right angles.



2. Let there be any one triangle A B C in which the sum of all the angles is two right angles. Make the angle B C D = A B C, and C B D = A C B, whence the triangle B D C is in all respects equal to A B C. Produce A B and A C each to double of its length, and join E, D, and D F. The angle C B E being equal to B A C and A C B together, and C B D being = B C A, it follows that E B D = B A C; whence the triangle E B D is in all respects equal to B A C, and the same, for similar reasons, is D C F. Hence the three angles at D are severally equal to those of the triangle A B C, or to two right angles; and thus E D F is a straight line, and A E F a triangle equiangular with A B C, and therefore having angles equal to two right angles. Or, if there be any such triangle, there is another of the same sort with double sides and the same angles; and since this process of doubling the sides may be repeated to any extent, it follows that, if there be any other given triangle, a triangle can be found with longer sides, and having the sum of its angles equal to two right angles.

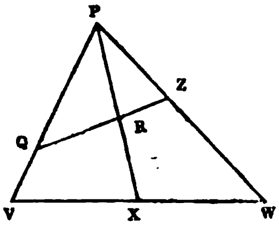


Next, any triangle A M N which has the angle A, must have the sum of all its angles also equal to two right angles. Continue the preceding process until the triangle A M N is completely inclosed, say in A E F, and join E, N. Then all the angles of the three triangles A M N, M N E, N E F, make up the angles at A, E, F (two right angles), those at M (two right angles), and those at N (two right angles); six right angles in all. Consequently each set of angles, in each triangle, must be equal to two right angles; for all three sets making up six right angles, no one set can fall short of two right angles, without another set exceeding it, which has been shown to be impossible.

Lastly, on the preceding assumption (namely, that there is one such triangle), every triangle has the sum of its angles equal to two right angles. Let P Q R be any triangle

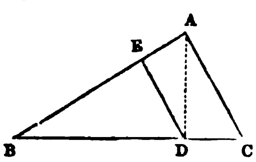
---

* The author of 'Geometry without Axioms' gives [illegible] for the axiom that [illegible] is only to be predicated of finite magnitudes. But without insisting on [illegible] of [illegible], or any one else, it is for the reader now to ask himself whether he can, by comparing the infinite spaces contained in equal and unequal angles, obtain a distinct conception of equality, of greater and of less. If so, the proof of M. Bertrand must be admitted by him; if not, he has a right to [illegible]. We are inclined to think that it is a proof to [illegible].



not equiangular with A B C; one of its angles must be less than one of the angles of A B C; for if not, the sum of the angles P, Q, R would be greater than that of A, B, C, or greater than two right angles. Let it be that P is less than A, and make Q P Z equal to B A C, constructing, by the preceding process of doubling the sides, a triangle V P W containing P Q R. Then since P V X has an angle (at V) common with P V W, the angles of P V X are together equal to two right angles, and because P V X has an angle in common with P Q R, the angles of the latter are also equal to two right angles. Hence, if any one triangle have its angles equal to two right angles, the same must be true of all triangles whatsoever.

3. If then we deny the preceding truth in the case of any one triangle, we must deny it in the case of all. Let it then be universally denied; and, taking any triangle A B C, take a point D, at which make the angle B D E = B C A. Then the angle B E D must be greater than B A C; for if not, D E A and E A C are at least equal to two right angles, and, E D C and A C D being together equal to two right angles, the angles of the triangles E D A, A D C, are together at least equal to four right angles, which is denied. For it is denied that either set is equal to two right angles, and it has been shown that neither set can be greater. In like manner it may be shown that if D move from C to B (the angle B D E being always = B C A), the angle B E D must continually increase, and can therefore only have a given value for a thereby determined value of B D. That is, by assigning the angles B, D, E, the side B D can be absolutely laid down. Now since angles might be given in numbers (taking the right angle, which is absolute, as a unit), it therefore follows that the length of a straight line might be handed down from generation to generation, by means of numbers only, without any dependence on a linear unit. This is the same conclusion as follows from the analytical proof, against those who would deny its conclusions.



We consider the preceding process as containing the most remarkable addition which has been made to the theory. With regard to the whole question, we do not consider the difficulty as one of a different kind from that of the quadrature of the circle or the trisection of the angle. In the earlier stages of mathematical investigation, all that was not evidently impossible was attempted, and failure was, properly and modestly, attributed to the want of sagacity in the investigators. In the instance before us, the object was to deduce positive properties from a purely negative definition, involving, be it observed, the idea of infinity. For if we say that parallels are lines which never meet, however far produced, we must, in the hypothesis 'let A B and C D be two parallel lines,' contemplate every point of both, however remote from A and B. The demonstration of M. Bertrand appears to us to assume considerations which are indispensable to the direct treatment of this negative definition; nor can we imagine the positive deduction of properties from the assumption of lines which never meet, without making their intervening space, as compared with other spaces, an object of reasoning. And even if the preceding process of M. Legendre should be allowed, so far as proving that one triangle only need be shown to have the sum of its angles equal to two right angles, and should the final theorem be ultimately completed by a less objectionable third process (of which we do not entirely despair), it may be doubted whether right reasoning will be promoted by the arbitrary rejection of notions intimately connected with those which are necessary for the perfect conception of a definition. On this the whole question must at last turn: it will readily be granted that a studied exclusion of a particular figure (for instance, of the equilateral triangle) would be no real gain to the strictness of geometry, even though it should be shown that the whole of Euclid might be established without it. The new considerations brought forward by M. Bertrand have not yet received the degree of attention which we will venture to prophesy must yet be given to them. When they have been maturely discussed, the following question will arise:—In admitting the notion and definition of parallels, and rejecting the comparison of their intervening spaces with angular spaces, are we, or are we not, in the position of those who admit one notion, while they exclude another which is as much of kin to the first as that of an equilateral triangle to any other triangle? We should be sorry to see this question settled either way without such an examination of the nature of our ideas of magnitude, and in particular of the connection of finite and infinite, as has not yet been made.

PARA'LYSIS (a Greek word, παράλυσις, which signifies literally a 'loosening' or 'relaxation') is the diseased condition in which the natural power of sensation or motion is lost in any part of the body.

In the article Nerve and Nervous System, the distinction was pointed out between the nerves of sensation and of motion, and it was stated that though most of the nerves distributed through the various parts of the body contain filaments of both kinds within the same sheath, yet the two orders of filaments are distinct in their origins and arise from separate portions or tracts of the brain and spinal chord. From this circumstance the differences betweeen the principal varieties of paralysis arise. If a sensitive nerve, or the tract of nervous matter from which the sensitive nerves of any part arise, be destroyed or seriously diseased, there will be a loss of sensation in that part, but its natural power of motion will remain; if the same injury befal a motor nerve, or a centre of origin for motor nerves, the part supplied therefrom will lose its motion, but retain its sensibility; and if a mixed nerve, or both nervous centres simultaneously, be affected, there will be a loss at once of sensation and of motion. Hence we have two distinct kinds of paralysis—loss of sensation, which is sometimes called *anæsthesia*, and loss of motion, to which the term paralysis, or palsy, is by some exclusively applied.

Each of these varieties of paralysis may vary in its degree of severity, or in the extent of the part of the body which it affects. For example, either kind may be *complete* or *incomplete:* in the former, the sensation or loss of motion, or both, are completely destroyed; in the latter, they are only impaired In its varieties of extent, paralysis of sensation may affect either a single nerve, as in loss of sight when dependent on disease of the optic nerve [Amaurosis]; in loss of smell, or anosmia, from affection of the olfactory nerve; in deafness, from disease of the auditory nerve; and loss of taste, from disease of the nerves appropriated to that function: or it may affect the sensitive nerves of a limb or of a variable portion of the body. In like manner paralysis of motion may affect a single muscle, as in *ptosis*, or dropping of the eyelid, from disease of the third nerve; or it may occur in a part of the muscles of the face, or the muscles of one or more limbs, or of a part of the trunk and limbs. Lastly, whole regions of the body may be paralysed; and of these cases the chief varieties are, *hemiplegia*, in which one side—half of the body—is deprived of sensation or motion, or of both; *paraplegia*, in which the lower part of the body is paralysed, while the upper retains both sensation and motion; and general paralysis, in which the loss of nervous power extends over nearly every part of the body.

Other varieties of paralysis are described from peculiar circumstances in their cause or symptoms; as *lead*-palsy, which is produced by the influence of lead, either locally applied, as to the hands of painters, or received into the system generally; *creeping* palsy, which, commencing in a limited part of the body, gradually extends over a larger portion of it; *shaking* palsy, in which the loss of motion being incomplete, any attempt at its exercise is effected by a trembling unsteady action, like that of a fatigued muscle.

The conditions under which these various forms of paralysis arise are numerous. Its most common and general causes are those which mechanically destroy that condition which is essential either to the conduction of sensitive impressions to the brain and to their perception by the mind, or to the conveyance of the stimulus of the will through the nerves of motion to the muscles. Thus pressure on the brain, by a fracture and depression of the skull [Head, Injuries of], or by a large effusion of blood [Apoplexy], or by large tumours, or an excessive fulness of the arterial or venous system of the brain, may, by preventing the free circulation of the blood through every part of its substance, produce general paralysis. Disorganization of the brain by softening or other excessive change of structure has the same effect, but often in a less degree, producing not a complete loss, but an im-privation of nervous power. Injuries of the same kind affecting only one side of the brain produce hemiplegia, the loss of power existing on the side of the body opposite to that on which the brain is compressed, in consequence of the decussation of the nerves which takes place at the medulla oblongata. [BRAIN.]

In like manner a similar compression of the spinal chord in any part will produce a paralysis of all the parts of the body whose nerves come off below the level of the injured part; and a similar obstruction applied to a single nerve will affect only that part which it supplies. The effect is the same, whatever be the nature of the cause preventing the performance of the functions of the nerves or their centres; the results of each differing only in the suddenness or slowness, or the degree of intensity with which its symptoms are produced.

There are some other but rarer and generally less serious forms of paralysis, in which no material change is discoverable in the structure of the nervous system. These are called functional or idiopathic paralyses; but it may be reasonably doubted whether they do not all, or for the most part, depend on some alteration not yet discovered, and perhaps incognizable by our present means of investigation. Such paralyses occur in some anomalous forms of nervous diseases, as in hysteria, and appear to be connected by sympathy with disorder of the uterine or digestive functions; they are also not unfrequently produced by the introduction of poisons, as in those who work with lead or mercury.

General paralysis, in which all sensation and voluntary motion are impaired or lost, is most commonly the result of apoplexy, or of severe injury to the head, producing concussion or compression of the brain; and indeed it may be said to exist in all cases of complete coma or insensibility. More rarely it is produced gradually; the patient losing in succession the power of motion in all his muscles, and at last existing only with an internal life, but disabled from all active communication with the external world. This state is usually the result of disease of the brain or spinal chord gradually spreading through their substance; and especially of disease of the latter spreading upwards.

The most frequent if not the only cause of paraplegia is injury or disease of the spinal chord; and this may originate in its own structure, or be produced by injuries or diseases of the vertebral column or other parts surrounding it. Paraplegia, when the result of disease, commonly affects first the lower extremities and the parts below the level of the pelvis, because the first part affected in the greater number of diseases is the lower portion of the spinal chord, from which the nerves supplying the lower extremities and pelvic viscera are derived. When produced by injuries of the vertebral column however, the paraplegia may from the first affect the body to a much higher level; its extent being always determined by the height in the vertebral column at which the injury is inflicted. In either case the disease, whether original or consequent upon injury, tends to spread up the chord; and with a corresponding progress, the paralysis rises up the trunk, and affects successively the chest and arms, terminating in death when the disease has reached the origin of the phrenic nerves, upon which the movements of the diaphragm depend.

In this form of paralysis, when all sensation and voluntary motion are destroyed, it is not rare to find involuntary movements produced by irritating the skin of the insensible parts. These motions are of the class which are referred to the reflex action of the spinal chord [NERVE]; the power of conducting impressions to and from the brain is lost, but the power which the chord possesses of exciting motions when impressions are made upon it, remains. The patient thus affected is indeed, as far as his nervous system is concerned, in the same condition as a beheaded animal; and the motions produced by irritating the parts below the diseased or injured portion of the chord are of the same kind as those observed after decapitation.

In paraplegia the parts deprived of nervous connection with the brain are, even more than in any other form of paralysis, liable to mortification when long subjected to pressure; and hence the sloughing of the back, which so commonly tends to shorten the patient's life. The sensibility to the pain produced by long continued pressure being destroyed, the patient would not be inclined, even if he were able, to make those frequent changes of posture by which a healthy person avoids its dangers.

Hemiplegia, in which the paralysis is confined to one side of the body, usually affects (as paraplegia does) the sensitive and the motor nerves simultaneously. This is by far the most frequent form of paralysis, and is that by which those popularly called paralytic are usually affected. Hemiplegia generally occupies exactly one-half of the body, the middle vertical plane separating the healthy from the paralysed portion. It is at once easily recognised in any patient by the flatness and smoothness of the affected side of the face, by the angle of the mouth being drawn over towards the opposite side, and by a general awry position of the features. The arm hangs powerless by the side; and in walking, the patient drags the affected leg after him, or, raising it from the ground by depressing the opposite side of the pelvis, lets it swing forward with its toe pointed towards the ground like a pendulum. Hemiplegia is most frequently the consequence of apoplexy [APOPLEXY], remaining after the patient has recovered from the complete insensibility or general paralysis by which the seizure was at first followed. More rarely it appears to arise from other causes, and is not preceded by any fit, but is developed by degrees from slight to perfect loss of nervous power.

The varieties of paralysis in which single and small portions of the body are affected, do not in general continue permanently limited to the part first attacked, but are often precursors of the more general affections already described. The most important forms, and those in which the paralysis most frequently remains for a long time local, are those in which the eyelids or muscles of the eye, and those in which the muscles of the face are affected.

In paralysis of the muscles of the eye, the most commonly affected are the elevator of the upper eyelid and the orbicular muscle of both the eyelids. When the former loses its power, the eyelid drops, and the eye is constantly more or less closed; when the latter is affected, the eye cannot be shut, and remains permanently wide open. The dropping of the upper eyelid (or ptosis) is dependent on a disease or injury of the third pair of nerves, and is usually accompanied by a paralysis of some of those muscles of the eyeball which are supplied by the same nerve; so that the position of the eye is altered, or it cannot be freely moved. The permanent openness of the eye is the result of disease of the seventh or facial nerve, or of its branch supplying the orbicular muscle; sometimes this latter branch alone is implicated, but more frequently the whole trunk is affected, and there is coincident paralysis of all the muscles of the face. As far as regards their influence on vision, both cases are almost equally injurious; the first by placing a veil constantly over the front of the eye; the second by destroying the power by which particles of dust, &c. are removed from the surface of the eye, and thus leaving it exposed to the dangers of constant irritation and inflammation.

In paralysis of the face many different conditions are observed, according to the nerve which has been diseased or injured. The sensation of the face depends entirely on the sensitive or larger portion of the fifth pair of nerves [BRAIN], the motion of its muscles on the seventh or facial nerve, and the motion of the muscles of mastication on the motor or small portion of the fifth pair. Now if either of these three nerves or their sources in the brain be separately injured, the paralysis will be limited to a loss of sensation, a loss of the motion of the muscles of the face, or a loss of the motion of those of the jaw, on the side affected. In the most frequent cases of affection of the fifth nerve, both its sensitive and motor portions are injured, and there is both a loss of motion of the muscles of the jaw and a loss of sensation of the whole of the skin of one side of the face.

Lastly, a limb, or a part of a limb, or a single muscle or set of muscles in any part of the body, may be paralysed. In some cases such an affection is only a sign of disordered digestion, and thus they occur chiefly in children; in others it exists in what is called general nervousness, as in hysterical women, who, with many other strange disorders, sometimes lose the power of swallowing or speaking. Most frequently however these forms of local paralysis depend on injury of the nerves of the part, which are compressed by tumours or involved in some diffused disease.

An important class of local paralytic affections includes those in which recent investigations have detected the sources of many cases of congenital or acquired deformity, such as club-foot, curvature of the spine, squinting, &c. In these, one or more muscles of a limb or organ being from birth or from childhood weak or powerless, its antagonist muscles draw the part into an unnatural position, and hold it there firmly and permanently fixed. One of the most important achievments of modern surgery is the cure of these affections by the division of the contracted muscle or its tendons. Such operations for club-foot and wry-neck are now commonly performed; and Professor Dieffenbach of Berlin has within the last few months cured three cases of squinting by a a similar proceeding.

These however are the only cases in which general rules of treatment can be laid down. The varieties of causes from which paralysis may arise afford sufficient evidence that its treatment in different cases must vary greatly. It cannot indeed be said to be a disease of itself, since it is only a sign of some disorder of the nervous system, which is often seated at a distance from the part whose motion or sensation is lost; this disorder also is of no definite kind, but may be the result either of hæmorrhage, or inflammation, or slow structural change of the nervous substance; or it may be produced by the pressure of fractured bones, or tumors, &c. In each case therefore the cause of the paralysis must be treated before there can be any expectation of removing its effects; and for this portion of the treatment the principal means are detailed in the article APOPLEXY.

PARAMARI'BO. [GUYANA, DUTCH.]

PARAMATTA, a town in the British colony of New South Wales, situated in Cumberland county, at the mouth of the small river Paramatta, and at the head of the harbour of Port Jackson. Its distance from Sidney, the capital of the colony, is 18 miles by water and 15 miles by land. The population of the town in 1836 consisted of—

	Males.	Females.	Total.
Free—under 12 years old	504	412	916
above 12 years old	875	659	1534
Convicts . . .	387	763	1150
Total . .	1766	1834	3600

The large proportion of female convicts is occasioned by the establishment within the town of a penitentiary wherein such persons are confined before they are assigned for service, and where they are returned by settlers on the hands of the government. The building is further used for the confinement of females guilty of offences within the colony.

The principal street is a mile long; at the end farthest from the harbour is the country residence of the governor of the colony.

The town, when first founded, was called Rose Hill, but the native name of the river on which it stands has since been given to it. There is daily communication with Sidney by means of stage-coaches and steam-boats.

The observatory at Paramatta (founded in 1821) was the private observatory of Lieut.-General Sir Thomas Brisbane, an active and well-informed astronomer, during his residence in the colony as governor. At his return to England, the government adopted it as a public establishment, and it is now under the superintendence of an observer appointed by the Admiralty. For an account of this observatory, see 'Memoirs of the Astronomical Society,' vol. iii., p. 399.

PARA'METER. This term was first used in reference to the conic sections only, in which it was synonymous with latus rectum; that is, the perpendicular drawn to the axis through a focus, terminated both ways by the curve, was the parameter of the curve. It was afterwards used to denote any straight line or even numerical co-efficient, by the value of which one individual curve of a species may be distinguished from the rest. Thus the curve whose equation is $y = ax + bx^2$ has two parameters, a and b. This last phraseology is not in general use, and seems to have been reserved only for questions in which what is called the variation of parameters is to be employed. Thus when in the planetary theory the motion of a planet is ascertained by determination of the variation of the instantaneous ellipse [GRAVITATION; ORBIT], and of the motion in that ellipse, in contradistinction to determining the motion in longitude and latitude separately, the method of variation of parameters was said to have been employed. But the *parameters* of the orbits are now generally called their *elements;* and the first term is little used, though it occurs frequently enough to require notice in a work of reference.

PARAMICIPPA. [MAIIDÆ, vol. xiv., p. 300.]

PARAMITHIA, or PARAMYTHI'A, called by the Turks, Aidonát Kálesi, or the castle of Aidonat, or Ai Dho[illegible] (a corruption of Ἅγιος Δονάτος, St. Donatus), an inland town in the province of Albania in European Turkey, about 14 miles north of Parga [PARGA]; in 39° 32′ N. lat. and 20° 44′ E. long. The town is situated in the mountainous district which skirts the valley of the Vuró, probably the antient Cocytus, the inhabitants of which mountains maintain a partial independence, and are half shepherds, half warriors, or robbers. The city covers a large space of ground, and contains many good houses; it is situated on the slope of a mountain, the summit of which (about 1000 feet about the level of the plain) is precipitous, and is crowned with a castle. Almost all the habitations are formed into distinct groups, occupied by family alliances, which are often at war with each other. The houses are built of calcareous stone, roughly hewn from the mountain on which the town stands, and are shaded by luxuriant plane-trees, beneath which are fountains of delicious water. The fortress is extensive; in the substructure of its walls are many portions of antient masonry, and in one angle is an antient gateway, four feet wide, formed of three stones, now walled up. In the steep and rugged ascent from the town to the fortress are many large isolated dwellings, surrounded by gardens and having loopholes adapted for musquetry instead of windows, an indication of the unsettled condition of the county. The bazar is spacious, shaded with plane-trees, and cooled by delicious fountains. Beside the fortress or 'old castle,' there is a small fortress, or guard-house, called Galatà, on another insulated rock. To this fortress many additions were made by Ali Pasha. Some antient masonry of the foundations show that this summit was included in the antient Epirote city on whose site Paramythia stands. The population was estimated by Dr. Holland, who visited the town in 1813, at 9000, chiefly Mohammedans. There were five mosques and a Greek church. It was at that period the seat of a Greek bishopric conjointly with Parga, the bishop taking his title from both places. Subsequent statements reduce the population to 3500; a diminution resulting probably from the ravages and convulsions to which the country has been subject of late years. Paramithia was a leading member of the Souliot league against Ali, and was generally united with Marghariti, Gardhiki, and Draghomi. But these towns were frequently, when not pressed by external danger, at war with each other; and when this was wanting, the parties in each town were seldom long without fighting. Ali acquired possession of the town, partly by treachery, after the fall of Suli.

As in other Albanian towns, all the common articles of Albanian or Turkish dress are manufactured here chiefly by Mussulmans. The Greeks are for the most part only retail shopkeepers.

Paramithia occupies the site of an antient city of considerable extent and importance, though it has not been certainly identified with any name mentioned by antient writers. Perhaps it was one of the castles of St. Donatus repaired, according to Procopius, by Justinian. Several exquisite antient bronzes have been discovered in excavations, some of which were in the collection of the late R. P. Knight, Esq.

(Holland's and Hughes's *Travels in Albania;* Leake's *Travels in Northern Greece; Dictionnaire Géographique Universel.*)

PARAMI'THRAX. [MAIIDÆ, vol. xiv., p. 299.]

PARAMO'RPHIA, or THEBAIA, a vegetable alkali obtained by MM. Theboumbry and Pelletier from opium, in 1835. The former name was given to it because its composition, according to the analysis of Pelletier, appeared to be similar to that of morphia: by M. Couerbe it has been called thebaia; and by his analysis, as also by that of Dr. Kane, it appears to contain less oxygen than by that of Pelletier. This name is indeed most commonly adopted.

Paramorphia is white; its taste is rather acrid than bitter; it is scarcely soluble in water, but is readily dissolved by alcohol and æther, and most so when hot. By spontaneous evaporation these solutions yield paramorphia, which, from the æthereal solution, has the form of flat rhomboidal crystals possessing considerable lustre. This substance has strongly marked alkaline properties, dissolves readily in dilute acids, and is precipitated from them by the alkalis. The acid solutions do not yield crystals by evaporation.

Paramorphia differs from morphia in not reddening concentrated nitric acid, in not becoming blue with the salts of iron, and in yielding no crystallizable salts with the acids. It melts at 266°, and this distinguishes it from me-

[illegible] and narcotina, which fuse respectively at 194°, 302°, and 338° of Fahrenheit.

The following are the results of the analysis of this substance by the authors named:—

	Pelletier.	Couerbe.	Kane.
Carbon	71·310	71·976	73·98
Hydrogen	6·220	6·460	6·96
Azote	4·460	6·383	6·94
Oxygen	17·999	15·172	13·01
	100·	100·	100·

According to Magendie, paramorphia acts strongly on the animal economy, resembling brucia and strychnia in this respect.

PARAMOUNT. [Title.]

PARANA, River. [Plata, La.]

PARAPET (from the Italian *parapetto*, compounded of the Greek preposition *para*, 'against,' and *petto*, 'breast'), a low or breast-high wall or fence, to serve as a protection on bridges, terraces, platform roofs, &c., whence it is termed in German *brustwehr*, or breast-guard. In Italian architecture, parapets are generally balustrades. In Gothic architecture, the parapet is merely a continuation of the wall carried up above the edge of the roof, and finished by a coping; unless machicolated, in which case it projects and overhangs the walls below. [Machicolation.] In the Lombardic buildings of Italy there is seldom any parapet, the eaves of the roof finishing the elevation. The same is frequently the case in the Norman style, or else the parapet is quite plain; whereas in Gothic architecture it is generally embattled, even in ecclesiastical buildings, and both the battlements and the crenelles or spaces between them have usually moulded copings. In what is called Decorated Gothic, parapets and battlements are frequently enriched with pannels, or a parapet without battlements is so embellished. East Basham manor-house is a fine specimen of such decoration in domestic architecture. (Pugin's *Goth. Examples*, vol. i.) In many cases such pannelling is perforated; nor are open-work parapets of quatrefoil ornaments and other carved patterns by any means uncommon. At a later period instances occur of open-work for such purpose, forming the letters of some motto, date, or inscription. In Elizabethan buildings open-work parapets, forming various fantastical devices, are common.

PARAPHERNA'LIA. This term comprehends the dress and ornaments of a wife which she occasionally wears, and which she is entitled, under some limitations, to retain after her husband's decease. It cannot be accurately stated how much a wife may claim as her paraphernalia; for this will depend on the rank and fortune of the husband and wife. A widow is entitled to retain as paraphernalia ornaments which she has received from her husband, provided she has worn them occasionally. The wife cannot give or bequeath such paraphernalia during her husband's life, nor can her husband bequeath such paraphernalia so as to deprive her of them; but he can sell them or give them. The wife's paraphernalia are liable to the payment of the husband's debts, unless the articles were given to her by a stranger before marriage or after marriage; in such cases the articles are considered as gifts to the separate use of the wife, and are accordingly neither at the disposition of the husband nor liable to the claims of his creditors; but if such gifts are to be considered as the separate estate of the wife, they are not properly paraphernalia.

The widow is entitled to her paraphernalia in preference to any claim of legatees; and if specialty creditors of her husband have taken her paraphernalia for payment of their debts after the personal estate is exhausted, she has a right to reimburse herself out of the real estate which has descended to the heir.

The term paraphernalia is derived from the Greek *parapherna*, a term which the Roman lawyers adopted to express what in their own language could not be expressed by a single word, and which was expressed by the periphrasis of *peculium* or *extra dotem*. The parapherna comprised the things which the wife brought to the husband's house, and which were not part of her *dos*. The common practice at Rome was for the woman to make out a list of such things as she used, clothing, &c., which list was signed by the husband, as an acknowledgment of receiving them, or at least of receiving them into his house. This practice, derived from the Roman law, is still in use in some countries of Europe. The husband did not obtain the ownership of the things included in such list, and in case of a separation, they were restored to the wife: if they were not restored, she could recover them by an action framed according to the circumstances of the case. (*Dig.*, 23, tit. 3, s. 9.) It must be remembered that the Roman *dos* is a different thing from the English *dower*, though some English writers on law have confounded them. (Roper, *Law of Husband and Wife*, 'Paraphernalia.') [Marriage.]

PARAPHRASE (from the Greek παράφρασις). A paraphrase partakes of the nature both of a version, if the work paraphrased be in a foreign language, and of a commentary. Its object is to express the full sense contained in the words which are paraphrased, by the introduction of circumlocutions, explanatory clauses, and expansions of the author's meaning. A paraphrase, if well and honestly executed, is an excellent mode of giving a connected interpretation of a whole work. The faults to which this sort of commentary is most liable are an alteration of the author's sense, and a degree of weakness and tediousness resulting from the use of unnecessary words. The latter fault is very remarkable in Doddridge's excellent work 'The Family Expositor.'

PARAPLEGIA. [Paralysis.]

PARASANG (ὁ παρασάγγης), a Persian measure of length, which, according to Herodotus (ii. 6; v. 53; vi. 42), was equal to 30 stadia; and if we reckon eight stadia as equal to one English mile, the parasang was consequently equal to nearly four English miles. Hesychius and Suidas also give the length of the parasang at 30 stadia; and Xenophon must have calculated it at the same length, as he says (*Anab.*, ii. 2, s. 6) that 16,050 stadia are equal to 535 parasangs (16,050 ÷ 535 = 30). Pliny (*Hist. Nat.*, vi. 30) however informs us that the length of the parasang was reckoned differently by different authors; and Strabo states (xi., p. 518, Casaubon) that some reckoned it at 60, others at 40, and others at 30 stadia. The Arabic geographers (see Freytag, *Lex. Arab.*, sub Farsakh) reckon it equal to three miles; which agrees with the statements of English travellers (quoted by Rödiger, in Ersch and Gruber's *Encyclopädie*), who estimate it variously at from 3½ to 4 English miles. Franklin (*Tour to Persia*, p. 17) reckons it at 4 miles; Ouseley (*Travels*, vol. i., p. 23) at between 3½ and 3¾ miles; and Kinneir (*Geogr. of Persia*, p. 57) at 3½ miles.

Parasang is a Persian word, and is derived from the ancient farsang, which is pronounced in modern Persian, ferseng. It has been changed in Arabic into farsakh. Various etymologies of this word have been proposed. The latter part of the word is supposed to be the Persian *seng*, a stone, and the word might thus be derived from the stones which were placed to mark the distances in the road. Bohlen (quoted by Rödiger) supposes the first part of the word to be the preposition *fera*, and compares the word with the Latin *ad lapidem*.

PARASITICAL PLANTS are those which grow upon the living parts of other plants, from whose juices they derive their nutriment, a circumstance by which they are immediately distinguished from false parasites, or epiphytes, which merely fix themselves upon other plants without deriving food from them.

Parasitical plants, properly so called, are extremely numerous, and belong to various parts of the vegetable kingdom. Some attack their victims externally, others are insidiously introduced into the interior, where they flourish until they pierce through the skin, place themselves in communication with the open air, and disseminate themselves; hence, physiologists divide them into *intestinal* and *superficial*. The former are exclusively fungi, and appear under the forms to which the popular names of mildew, rust, brand, smut, &c. are applied; it is among the latter that parasites of so many different kinds are met with. These are again divisible into such as have true leaves, green, and capable of acting, in the manner of ordinary leaves, as organs of respiration and digestion; and such as have scales, brown or some colour not green, in the room of true leaves, without any powers of digestion or assimilation, except in a low degree. The first, or *leafy* or *green parasites*, elaborate their food for themselves; the second, or *scaly* or *brown parasites*, obtain it in a state of elaboration from other species.

Green leafy parasites belong exclusively, as far as is yet known, to the genera Viscum and Loranthus. The viscid seeds of these plants strike root upon any solid body on which they fall; if it is not suited to support them, as in the case of stones, rocks, or any inorganic substance, the seed soon perishes; but if it is capable of yielding them nutrition, as the leaf or branch of a tree, the young root immediately forms a kind of convex disk, which adheres firmly to the surface, and by degrees introduces itself into the interior so as to place itself in communication with the fluid contents of the plant on which it has germinated. In general it is a matter of indifference to such parasites to what plants they attach themselves: poplars, willows, apple and pear trees, elms, oaks, limes, spruce-firs, Scotch pines, vines, ashes, and many other trees, have all been seen attacked by the mistletoe, which, according to Pollini, has even been found upon the *Loranthus Europæus*, itself a parasite, and a similar case of double parasitism has been noticed in the Loranthus buxifolius attacked by Loranthus tetrandrus. In the opinion of De Candolle, this indifference as to the stock on which it grows is to be accounted for upon the supposition that such parasites are only in communication with the young wood, through which the crude sap, not very different in its nature in different trees, ascends, and whence it is in that state conveyed for the use of the parasite. The same author states, with reference to this point, that if a branch of mistletoe is plunged by the lower end into water, it pumps up only a minimum quantity, while, if the limb of the plant on which it grows is cut off and placed in water, the mistletoe causes the absorption of water, just as the leaves would of the plant itself. Such plants as these are sometimes very injurious to the trees they attack, bearing them down by their weight, and robbing them of the food intended for their own leaves and fruit. When this happens, abscission is the only known remedy, and if carefully followed up, it must be successful.

Brown scaly parasites always attack the roots of plants, and their underground habits have caused them to be little examined. The most common species in Europe are various kinds of *Orobanche*, which attack hemp, clover, lucern, and many other crops; *Monotropa* and *Lathræa*, which infest the roots, the first of the fir, and the second of the ash; in other countries Rhizanths abound [RHIZANTHS], and probably many others of which we have no sufficient knowledge. To these are usually added *Neottia Nidus Avis* and *Corallorhiza innata*, two orchidaceous plants, concerning whose real habits we have however no precise information. The best account of the manner of growth of brown parasites is by Mr. Bowman, who studied with care the habits of *Lathræa squamaria*. In that plant he found that the fibres of the roots are each tipped by a tubercle about as large as a pin's head, which tubercle attaches itself to the roots of the ash-tree, and gradually buries itself in the bark until it gets into communication with the wood, from which it derives its nutriment. One of the most remarkable peculiarities of such plants as these is the constant absence of all green colour, although exposed to the brightest light. Orobanches grow in pastures and open places, and yet their scale-like leaves indicate no visible tendency to any colour except brown or purple; and in Lathræa Mr. Bowman has shown that the same thing always happens, although the plants associated with it in its growth are as green as usual. Connected with this is another curious property, that of resisting the attraction of light, towards which all the green parts of plants irresistibly tend; in Lathræa, when the flower-stems have acquired their full stature, they are always perpendicular, and in groups of 20 or 30; in the most umbrageous situations the rows of flowers, which have always a unilateral direction, are as frequently turned from the only side on which light is admitted as towards it.

In addition to these superficial parasites there are numerous kinds of fungi which frequently commit great ravages among the plants on which they prey. *Rhizoctonia crocorum* seizes upon the bulbs of the saffron in the warmer parts of Europe, and spreading its long flexible arms around them, robs them by degrees of all their vital fluids. Many others have already been named in the article MILDEW.

(For detailed information concerning parasites, see Bowman, in the *Transactions of the Linnean Society*, vol. xvi., p. 399; and De Candolle's *Physiologie Végétale*, p. 1401.)

PARASYTES NAGEURS, M. Milne Edwards's name for a legion of his subclass *Crustacés Suceurs*. The Swimming Parasites consist of the orders *Siphonostomes* and the *Lerneans*. In the same subclass are placed the *Parasytes Marcheurs*, or Walking Parasites, consisting of the order *Araneiformes*. [SUCTORIAL CRUSTACEANS.]

PARCÆ (Μοῖραι), the Fates, were goddesses who were supposed to preside over the destinies of man. In Homer we only read of one deity, Μοῖρα or Αἶσα, whose decrees even the gods cannot escape; but in Hesiod and all succeeding poets we read of three Fates: Clotho (Κλωθώ), the 'Spinster;' Lachesis (Λαχέσις), the 'Distributor;' and Atropos ("Ατροπος), the 'Unchangeable.' In one passage Hesiod (*Theog.*, 904) calls them the daughters of Zeus and Themis; and in another (*Theog.*, 217), the daughters of Night, which agrees with the statement of Cicero (*De Nat. Deor.*, iii. 17), who makes them the daughters of Night and Darkness (Erebus). This contradiction seems to have arisen from the different notions entertained by the antients respecting the relative power of Zeus and the Fates, since they were sometimes represented as ruling the gods and Zeus himself, and at other times as merely carrying into effect the determinations of Zeus. In the antient Greek writers, and especially the tragic poets, the gods themselves are represented as subject to the decrees of fate; but in later times the Fates appear to have been generally regarded as subject to Zeus. Thus we learn from Pausanias (v. 15, s. 4; x. 24, s. 4) that Zeus was worshipped both at Olympia and Delphi under the name of Μοιραγέτης, or 'Leader of the Fates,' which title was also applied to Apollo at Delphi. (Paus., x. 24, s. 4.) Pausanias, in describing (i. 40, s. 3) a celebrated statue of Zeus at Megara, on the head of which the Fates (Μοῖραι) were placed, remarks that this was done because destiny (τὴν πεπρωμένην) is obedient to Zeus alone.

The Fates are usually spoken of by the Greek and Roman poets as spinning the destinies of men (*Il.*, xx. 128; *Od.*, vii. 197); and according to mythologists, each of the three presided over different periods of human life; Clotho over the beginning, Atropos the end, and Lachesis the general course of the life of each individual. Apuleius (*De Mundo*, p. 280, Bipont), whose opinion however can scarcely be regarded as representing the popular belief upon the subject, assigns a different office to each of the Fates. Atropos he regards as the fate of past time, Lachesis of future, and Clotho of present events.

There was a temple at Lacedæmon sacred to the Fates (Paus., iii. 11, s. 8), and there were also altars sacred to them in the neighbourhood of Sicyon. (Paus., ii. 11, s. 4.) They had also in later times a small temple at Rome in the eleventh district (regio) of the city (Onuphr. Panvin. apud Rosin., i., c. 13); but their worship seems to have prevailed at Rome to a very small extent.

PARCENERS, or COPARCENERS, are so called because the lands of which they are parceners may be partitioned or divided among them. There may be parceners by common law and parceners by custom.

As to parceners by common law, if a man dies intestate seised of lands in fee, and leaves only daughters, the lands will descend equally to all the daughters, or if he has no daughters and no brothers, the lands will descend equally to all his sisters, if he has any; and if there are no nearer heirs, the lands will descend to his aunts. The descent is the same if a man dies seised of lands in tail, except when the estate tail was limited to such man and the heirs of his body, for in that case the lands can only descend to those who are heirs of the body. In all cases where several females take one inheritance by descent, they are called parceners, and all lands or tenements, including a rent charge, may descend in this manner. If there be a title of dignity descendible to heirs of the body, the lands and tenements belonging to it may descend to parceners; but the dignity itself does not descend, for all the parceners only make heir, and a title of dignity is not in its nature divisible. The dignity therefore will be in abeyance. [BARON, p. 488.]

The descent of the crown is an exception to this rule; for if there are several daughters, &c., and no male heir, the crown with all its rights descends to the eldest female. In the case of the high constableship of England, if there were parceners, the office was executed by the husband of the eldest daughter, and, before her marriage, by deputy.

Parceners resemble joint tenants in having a unity of title and one entire freehold; but the unity of title can only be by descent, and there is no survivorship among parceners: if one of them dies, her heir is parcener with the survivor or survivors. Parceners resemble tenants in common, in having each a moiety or several interest in the land which has descended to them. It follows from the nature of this interest, that one parcener may either enfeoff another parcener of her share, or release her share to such parcener. A a parcener aliene her undivided share before partition, the alienee is tenant in common with the other parceners.

Parceners may voluntarily make partition of the land among them; or any one might formerly compel her coparceners to make such division by a writ entitled *de partitione facienda*, which was also applicable to the case of *joint tenants* and tenants in common. The Court of Chancery in course of time acquired a jurisdiction in these matters, and a bill may be filed in chancery by a parcener, praying for partition, which prayer will be granted on the parcener making out her title. The partition is effected by issuing a commission out of chancery to commissioners, who set out and divide the lands, upon which the parties execute mutual conveyances. When partition is made, the several parceners hold their lands as several and distinct estates. Since the abolition of the writ of partition (3 and 4 William IV., c. 27), partition can only be effected by a suit in equity.

Coparcenary may exist among males and females. For instance, if a man has two daughters, and one of them dies in his life-time, but leaving a son and daughters, and then the father dies, the son of the deceased daughter will be coparcener with his aunt; for he must trace his descent through his mother, who, if she had survived her father, would not have been his heir, but together with her sister, who did survive the father, would have made his heir.

By a recent act (3 & 4 Will. IV., c. 27, s. 12) it is declared that when a parcener has been in possession of more than her share of the land, or in the receipt of more than her share of the rent, held in coparcenary, for her own benefit or for the benefit of some other person than her coparceners, such possession or receipt by her shall not be considered the possession or receipt of her coparceners.

When all the sons take the land equally among them by descent, as in the case of gavelkind lands in Kent, they are parceners by custom.

Coparcenary is not very common at present, lands being generally so settled as to prevent its occurrence. The chief rules as to coparcenary are stated in Comyns's *Digest*, 'Parcenary,' and in Littleton, b. iii., 'Of Parceners.'

PARCHMENT is the skin of an animal prepared for writing upon. The name is a corruption of the Latin *Pergamena*, from Pergamus, the alleged place of its invention.

Parchment is ordinarily made of the skin of sheep or lambs. Peignot states that for drums it is made of goat or wolf skins, and that the parchment with which church-books are covered is made of pigs' skins. Vellum is a finer, smoother, and whiter sort of parchment, made of the skins of very young calves.

Whatever may be the kind of skin used, the process of manufacturing is the same. When the skin is divested of its hair or wool, it is placed for some time in a lime-pit, and then stretched on a square wooden frame drawn tight by pegs. When in the frame, it is first scraped on the flesh side with a blunt iron, then wetted with a moist rag, covered with powdered chalk, and rubbed well with pumice-stone; after a short pause, these operations are repeated, but without chalk; the skin is then turned and scraped on the hair side once only; the flesh side must now be scraped once more and again rubbed over with chalk, which must be brushed off with a piece of lambskin retaining the wool. All this is done by the skinner, who allows the skin to dry in the frame and then cuts it out and sends it to the parchment-maker, who repeats the operations with a sharper tool, using a bench stuffed with flocks to lay the skin upon instead of stretching it in a frame.

Parchment is said to have been invented by Eumenes II., king of Pergamus (who reigned B.C. 197-159), in consequence of the prohibition of the export of papyrus from Egypt by Ptolemy Epiphanes. The probability is, that some improvement was made in the manufacture at Pergamus, but Herodotus mentions writing on skins as common in his time, and Ctesias and Diodorus describe the antient Persian records as written on leather. The name Pergamena has been thought to prove its invention at that place, but the word was not used until several centuries after the time of Eumenes. Titus, a monk of the fourth century, is, according to Mabillon, the first writer in whose works it is found written. Previous to his time the usual term was membrana, which is the word we find in the Greek Testament, 2 Timothy, iv. 13.

The antient parchment must have been exceedingly fine, if we are to believe the story of Cicero's having seen the 'Iliad' written on this material enclosed in a nut-shell; but for this we have only Pliny's authority. (*Hist. Nat.*, vii., c. 21.) That of the seventh to the tenth century is white and good, and at the earliest of these periods it appears to have nearly superseded papyrus, which was brittle and more perishable. A very few books of the seventh century have leaves of parchment and papyrus mixed, that the former costly material might strengthen and support the friable paper. About the eleventh century it grew worse, and a dirty coloured parchment is evidence of a want of antiquity. This may possibly arise from the circumstance, that writers of this time prepared their own parchment, and they were probably not so skilful as manufacturers. A curious passage from a Sermon of Hildebert, archbishop of Tours, who was born in 1054, is a voucher for this fact. The Sermon is on the 'Book of Life,' which he recommends his hearers to obtain. 'Do you know what a writer does? He first cleanses his parchment from the grease, and takes off the principal part of the dirt; then he entirely rubs off the hair and fibres with pumice-stone; if he did not do so, the letters written upon it would not be good, nor would they last long. He then rules lines, that the writing may be straight. All these things you ought to do, if you wish to possess the book which I have been displaying to you.' (Sermon 15., Paris, 1708, fol.) At this time parchment was a very costly material; we find it mentioned that Guy, count of Nevers, having sent a valuable present of plate to the Chartreux of Paris, the unostentatious monks returned it with a request that he would send them parchment instead. It had long been customary to erase antient writing from parchment by rubbing it with pumice-stone. When the custom began we do not know; Muratori cites a palimpsest of theirs nearly nine centuries old, and some have since been found of still more antient date. [Palimpsest; Gaius.] The practice was so common in the fourteenth and fifteenth centuries, that when the emperor of Germany empowered the creation of an imperial notary, one of the chief articles of his diploma was that he should not use scraped vellum in drawing deeds. But the invention of linen paper came in aid to the uses of parchment, and when its manufacture became cheap, it superseded the more costly article for all purposes except those in which luxury was aimed at or uncommon durability required.

PARDALOTUS. [Pipridae.]

PARDON. According to the laws of most countries, a power of pardoning, or remitting the penal consequences of a conviction for crimes before the judicial tribunals, is vested in the sovereign or in the chief magistrate. The utility of such a power has been doubted by juridical writers, upon the ground that it supposes an imperfect system of criminal law, and that every instance of its exercise is the proclamation of an error either in the law itself or in the administration of justice. (Beccaria, chap. 46.) There is no doubt that the nearer a penal system approaches to perfection, the fewer will be the occasions for resorting to extrajudicial remissions of the execution of the law; but considering the numerous causes of erroneous decision, arising not only from the imperfection of laws themselves, but from the infinite sources of error in the instruments and means by which they are administered, it seems to be desirable that some power should exist which may by timely interference prevent the occurrence of irremediable wrong in cases where the error cannot be corrected by any appellate tribunal. At the same time it is evident that such a power should be circumscribed and defined, as far as its nature will admit, and exercised with the utmost caution. By the law of England, besides pardons by act of parliament, the power of granting pardons for crimes is exclusively vested in the king as a branch of his prerogative. [Prerogative.]

Formerly, Counts Palatine, Lords Marchers, and others who claimed *jura regalia* by virtue of antient grants from the crown, assumed the authority to pardon crimes; but by the stat. 27 Henry VIII., c. 24, this power was entirely abolished, and the sole right of remitting the sentence of the laws was permanently vested in the king. The power of pardoning is applicable in all cases in which the crown is either concerned in interest or prosecutes for the public. The only exception to this rule is contained in the Habeas Corpus Act (31 Car. II., c. 2, s. 12), by which persons convicted of signing commitments of British subjects to foreign prisons are declared to incur the penalties of a praemunire and to be 'incapable of any pardon from the crown.'

The crown has however no power to pardon any offence in the prosecution of which a subject has a legal interest, or, as Bracton expresses it, 'non potest rex gratiam facere cum injuriâ et damno aliorum' (lib. iii., p. 132). Thus in appeals of death, robbery, or rape, the king could not pardon the defendant, 'because,' says Sir Edward Coke, 'it is the suit of the party to have revenge by death' (3 *Inst.*, 237). Upon the same principle, where an attaint was brought against a jury who had delivered a false verdict, and the party in whose favour it had been given was joined in the attaint, the king might pardon the *jury*, if convicted, because they were merely subject to an exemplary punishment; but he could not pardon the *party*, because the latter was liable to make restitution to the plaintiff who prosecuted the attaint. So also in indictments for common nuisances, where the public are interested as individuals or particular classes, or informations upon penal statutes, where the penalty or any part of it goes to the informer, or the party grieved, the crown cannot pardon the offender. Formerly, the crown appears to have exercised without restriction the power of pardoning offenders impeached by the Commons in parliament (Blackstone's *Commentaries*, vol. iv., p. 400—Christian's *Note*); but the lawfulness of the exercise of this power during the pendency of the proceedings was questioned by the House of Commons on the impeachment of the Earl of Danby in the reign of Charles II. (Howell's *State Trials*, vol. ii., p. 724); and by the Act of Settlement, 12 and 13 William III., c. 2, it was enacted 'that no pardon under the great seal of England shall be *pleadable* to an impeachment by the Commons in Parliament.' This statute however does not affect the power of the crown to pardon the offender after he has been found guilty upon the impeachment, and the proceedings are determined.

An effectual pardon from the crown must apply in express terms to the particular offences intended to be pardoned; and there must be no reasonable intendment, supplied by the recital in the pardon or otherwise, that the crown was deceived or misled as to any of the circumstances on which the grant was founded. Nor can any grant of a commission or protection by the king amount by implication to a pardon of any offence previously committed.

A pardon may be either absolute or subject to any condition which the crown may think proper to annex to it; and in the latter case, the validity of the pardon will depend upon the performance of the condition. Until the recent improvements in the criminal law of England, almost all felonies were nominally capital; and in the numerous cases where it was not intended that the sentence of death should be executed, the criminal obtained a pardon upon condition of his submitting to transportation or some other punishment. At the present day, where the crown interferes to mitigate or commute a sentence, the mode by which it is effected is by granting a conditional pardon.

It was formerly necesssary that every available pardon from the crown should be under the great seal; but by the stat. 7 and 8 Geo. IV., c. 28, s. 13, it is declared and enacted 'that where the king's majesty shall be pleased to extend his royal mercy to any offender convicted of any felony, punishable with death or otherwise, and by warrant under his royal sign manual, countersigned by one of his principal secretaries of state, shall grant to such offender either a free or conditional pardon, the discharge of such offender in the case of a free pardon, and the performance of the condition in the case of a conditional pardon, shall have the effect of a pardon under the great seal.'

The effect of a pardon is not merely to prevent the infliction of the punishment denounced by the sentence upon the offender, but to give him a new capacity, credit, and character. A man attainted of felony ceases to be *probus et legalis homo*, and can neither bring an action for damages nor be a witness or a juror in any legal proceeding; but upon receiving a pardon, all these legal disabilities are removed. In this respect a pardon by the law of England differs from the abolitio of the Roman law, to which in other points it bears a near resemblance. According to the latter, 'Indulgentia, quos liberat, notat; nec infamiam criminis tollit, sed pœnæ gratiam facit.' (*Cod.*, lib. ix., tit. 43.) By the English law a distinction is made as to the effect of a pardon where the incapacity is part of the legal sentence, and not merely a consequence of attainder, as in the case of perjury under the statute 5 Elizabeth, c. 9; where the incapacity or infamy is part of a statutory sentence, a pardon from the crown has been held not to restore the party, and in such a case nothing less than an act of parliament will have that effect. (Chitty's *Criminal Law*, vol. i., p. 776.) Some doubt has been expressed, and the point has not yet received a judicial determination, whether a royal pardon will fully restore a person convicted of a crime, such as perjury, which is considered infamous at the common law. This subject is elaborately discussed, and all the authorities carefully examined in Mr. Hargrave's 'Argument on the Effect of the King's Pardon of Perjury' (Hargrave's *Juridical Arguments*, vol. ii., p. 221).

PARE′, AMBROSE, the first and most eminent of the old French surgeons, was born in 1509, at Laval, in the province of Maine and the modern department of Mayenne. His parents were poor, and his education was neglected, but having one day witnessed the operation of lithotomy, he went immediately to Paris and commenced the study of surgery. He afterwards accompanied the French army during several campaigns in Italy, and gained so much reputation, that in 1552 he was appointed surgeon in ordinary to king Henry II. He held the same office under Francis II., Charles IX., and Henry III., until his death, at the age of eighty-one, in 1590. He appears to have been a pious and excellent man, and having been educated in the reformed church, he steadily refused to leave it. During the horrible massacre of St. Bartholomew's, he owed his life to his professional reputation and the personal friendship of the king, whom, as he tells us himself, he had especially obliged by having saved from the consequences of a wound accidentally inflicted on the median nerve in venesection. (*Opera Chirurg.*, lib. ix., cap. 38.) Brantome says, in his 'Memoirs,' that on the evening of the massacre the king sent for him into his bed-room, and told him not to stir out, saying that it was not right to murder a man who was so useful to the world (tom. iv.). The French writers justly consider Paré to be the father of modern surgery, and say that he holds the same rank in this branch of the profession as Hippocrates does in medicine. He was not satisfied with blindly following the precepts of his predecessors, but by diligent observation and reflection made several important changes in the mode of treatment, which have been followed to the present day. One of his greatest reforms was in the treatment of gun-shot wounds, into which it was the custom at that time to pour boiling oil; he was also the first person who left off the barbarous practice of cauterising a limb to stop the hæmorrhage after an amputation. He was the first who recommended the extraction of the fœtus by the feet in cases of difficult parturition (lib. xxiii., cap. 26). He says that in cases of ascites the fluid should *not* be drawn off all at once after paracentesis (lib. vii., cap. 12). Although he was not the discoverer of the art of tying the blood-vessels, he at least restored the practice, pointed out its advantages, and gave some excellent rules for performing the operation. His works are chiefly valuable and remarkable for the great number of facts and cases contained in them, and for the care with which he avoids giving any directions resting merely upon theories and unsupported by observations. They were published in a collected form at Paris, 1585, fol., in French, and are divided into twenty-eight books, of which the first five are chiefly on anatomical and physiological subjects. There are several other editions of his whole works, which have also been translated into Latin, Paris, 1582, fol., in twenty-six books; into English, London, 1578, fol.; into Dutch, Leid., 1604, fol.; and into German, Frankf., 1601, fol. (Sprengel, *Hist. de la Méd.*; Haller, *Biblioth. Chirurg.*; *Biogr. Méd.*)

PARE′DES, DIEGO GARCIA DE, a celebrated Spanish general, not undeservedly called 'the Spanish Bayard,' was born of noble parents, at Truxillo, a town of Estremadura, in 1466. Having early embraced the career of arms, he accompanied his father to the war of Granada (1485), and was present at the taking of Baza, Velez, and Malaga from the Moors. [Ferdinand; Moors.] It was there that he became acquainted with the celebrated Gonzalo de Cordova, under whom he afterwards served in Italy. Shortly after the taking of Granada (1492), which put an end to the Moorish war, Paredes, who had retired to his native town, determined to repair to Italy, then the theatre of war; but as he had neither horse nor armour, he stole those of a cousin of his, and secretly left his father's house. Scarcely however had he proceeded a few miles on his way, when he was overtaken and attacked by seven of his cousin's squires, of whom he killed two.

wounded two more, and put the remainder to flight. On arriving at Rome, he was well received by the Pope (Alexander VI.), who gave him a high command in his army. He served that pontiff with great zeal until 1499, when he left his service and enlisted under the banners of the Great Captain, who with a powerful fleet sailed towards the Morea. He was present at the taking of Cephalonia from the Turks (June, 1501), and was made prisoner in a sortie of the garrison, but he soon succeeded in extricating himself from the hands of the enemy. War having broken out (July, 1502) between the French and the Spaniards, who contended for the possession of the kingdom of Naples (Ferdinand V.; Louis XII.), Paredes rendered most important services by his military skill and his undaunted courage. At the celebrated pass of arms of Trani, he was one of the eleven Spanish champions who entered the lists, and, though enfeebled by the wounds he had received on a former occasion, he alone unhorsed three of the antagonists. At the storming of Ruvo (February, 1503) he led the scaling party, and was the first on the ramparts. He also distinguished himself at Cerignola, where he commanded the centre of the Spanish army, and signalized himself by defending alone on the bridge against a body of French knights, all completely armed, and contending successfully with them, until he was rescued by a party of his own men. According to Mariana (book ii, lib. 29, cap. 4), Paredes, having been, shortly after the death of the Great Captain (December, 1515), deprived of his estates by the restoration made to the Angevin lords, endeavoured to repair his broken fortunes by driving the trade of a corsair in the Levant. However this may be, Paredes continued to serve in Italy. He was present at the sieges of Verona and Vicenza, and also at the celebrated battle of Pavia (1525), where Francis I. was taken prisoner. [CHARLES V.]

Paredes died in 1530, at the age of 64. He always lived in great intimacy with Gonsalvo, whose brilliant qualities he appreciated, being one of his most zealous supporters when he fell into disgrace. Having one day, while in the presence of Ferdinand, overheard two noblemen speak slightly of his general, Paredes threw his gauntlet on a table, and said, 'Whosoever asserts that the Great Captain is not the king's best vassal, let him pick up this.'

Paredes wrote a short but highly interesting account of his own military campaigns and exploits, which is printed at the end of the 'Cronica del Gran Capitan.'

(Paulo Jovio, *Vitæ Illust. Virorum*, Basil. 1578; Guicciardini, *Istoria d'Italia*, vol. i., lib. 6; *Chronica del Gran Capitan*, Alcalá, 1584; Zurita, *Anales del Reyno de Aragon*, vol. iv.; Quintana, *Españoles Célebres*, vol. i.)

PAREIRA, a Portuguese name given in Brazil to the roots of certain plants employed in medical practice as valuable tonics and diuretics. The sort which is admitted into the Pharmacopœias of Great Britain is called Pareira brava, a climbing plant, with orbicular peltate leaves, small green racemose panicles of flowers, and scarlet hairy berries. It inhabits the West India Islands, in some of which it is known by the name of Velvet-leaf, as well as on the mainland of America, and is the *Cissampelos Pareira* of Linnæus. It is frequently administered in this country, especially in dyspeptic cases and in chronic inflammation of the bladder. Other kinds peculiar to the woods of Brazil are the *Cissampelos glaberrima* and *ovalifolia*, the properties of which appear to be altogether the same as those of the true Pareira. Besides these there is a white Pareira, found in Guzerat and the neighbouring countries, which is furnished by the genus Abuta, and which is principally employed as a diuretic. (Lindley's *Flora Medica*, Nos. 770 to 774.)

PAREJA, JUAN DE, born in 1610, is remarkable not only for an extraordinary love of the art of painting, but for having acquired a great degree of excellence while in a low and abject condition of life. He was a mestizo, that is, born in the West Indies, and the son of a Spanish father by an Indian woman; he became a slave of the celebrated Velasquez, who employed him in grinding colours.

He spent whole nights in drawing, and almost denied himself rest and sleep, imitating, as may be supposed, the manner of Velasquez. He was however under perpetual fear of being discovered by his master; till at length he hit on an ingenious mode of disclosing his secret. Having observed that Philip, king of Spain, who frequently honoured Velasquez by visiting him, always ordered any paintings which were placed with their face to the wall, to be turned, Pareja placed a picture of his own in that position; the king, as he expected, ordered it to be turned. He expressed his admiration of it to Velasquez, who however was taken by surprise, and declared that he knew nothing of it. On this Pareja fell on his knees, and begged the king to obtain his pardon of his master for having presumed to practise the art without his permission. Philip, being much pleased at this address and admiring a work produced under such singular circumstances, told Velasquez that a man who showed so fine a genius and possessed such talents ought no longer to be a slave. Velasquez, of course, immediately emancipated him. But he never quitted his master, and after the death of Velasquez continued to serve his daughter with the most grateful fidelity.

He was especially successful in painting portraits, which in style, colouring, and handling so exactly resembled the works of his master, that we are assured they could not be distinguished from them.

PARELLA (sometimes written *Perelle*), the French name of a crustaceous Lichen, *Lecanora Parella* of botanists, but which is applied to several species similar to it in habit, and employed for the same purpose, that is, for yielding a rich dye known by the name of litmus. The mode of preparing this is not well known, but it is probable that it is similar to that employed in the manufacture of Orchil. By French authors it is described as consisting in macerating the lichen for ten or twelve days in urine, with the addition of lime-water, when it acquires a violet colour and is changed into a soft pulp; it is then strained in a coarse cloth, and moulded into pellets, as seen in commerce. M. Guibourt is of opinion that the colouring matter is given by *Crozophora tinctoria*, or turnsol; this may be the case sometimes, but there can be no doubt that not only the parella but several other species of lichen are collected, and if not for this, for what other purpose do they form articles of commerce? In France even, several other species are employed, as well as the parella, which is especially called parelle d'Auvergne. The inhabitants of that province scrape the rocks for this lichen, which is said to be often intermixed with *Lichen* (now *Isidium*) *corallinum*, which is endowed with similar properties. De Candolle indeed states that most of the lichens with a crustaceous thallus are possessed of dyeing properties, and therefore it is probable, as stated by Guibourt, on the authority of Ramond, that with the above, *Variolaria orcina*, *dealbata*, and *aspergilla*, with *Lichen geographicus*, *scruposus*, and *sulphureus*, are employed in preparing litmus. We know indeed that in Great Britain several species have been used for yielding colouring matter. *Parella omphalodes* and *P. saxatilis*, for instance, used to form articles of commerce in the west of Scotland, being much used by the peasants for dyeing their woollen cloths of a dull brown colour. *P. tartarea* has been long employed, both by the Scotch and Welsh, also for dyeing woollens. It was brought into extensive employment by Dr. Cuthbert Gordon, who took out a patent for his process, converted his Christian name into Cudbear, and applied it to the dye-stuff employed to produce purple for dyeing woollen yarn. The parella and its best substitutes continue in great request, and bring higher prices than ever, from their increased scarcity.

PARENCHY'MA is the term which was applied by the old anatomists to an imaginary substance, through which they supposed the blood at the ends of the veins to be strained. Even after the discovery of the circulation, the mode in which the blood passes from the extremities of the arteries to the beginnings of the veins remained for some time unknown. Harvey seems to have hesitated between the hypothesis of the writers just preceding him, who believed that there were wide passages of communication between arteries and veins, and that of the more ancient authors, who spoke of a parenchyma, or spongy substance, a concrete blood which they supposed to lie between the vessels, and to constitute the chief mass of all the organs of the body. The discovery of the passage of the blood from arteries to veins through the minute capillary vessels was made by Malpighi, in 1661, by a microscopic examination of the circulation of a frog; and it afforded the only proof that was needed to render Harvey's demonstration of the circular motion of the blood perfect.

In the present day the term parenchyma is rarely used. If it has any definite meaning at all, it may be considered to express all that part of an organ, and especially of a gland, which lies in the interspaces of the blood-vessels and lytween the secreting ducts, that is, the common cellular tissue by which the more essential parts of organs are connected together.

PARENT AND CHILD. This relation arises only from a legal marriage. The relation between parents and their illegitimate children is considered in the article **Bastard**.

Parents are bound to maintain their legitimate children who are unable to maintain themselves owing to infancy or inability to work. This obligation extends to father and mother, grandfather and grandmother, if they are able to perform it (43 Eliz., c. 2). But such persons are only bound to furnish the children with the necessaries of life; and the penalty incurred in case of refusal is only 20*s.* per month. A husband is now (4 and 5 Wm. IV., c. 76) liable to maintain the children of his wife, born before marriage, whether they are legitimate or not, until they are of the age of sixteen, or until the death of his wife. If a parent deserts his children, the churchwardens and overseers may seize his goods and chattels, and receive his rents, to the amount mentioned in the justices' warrant, which must be obtained before such seizure is made.

If a Popish parent refuse to allow his Protestant child a suitable maintenance, with the view of compelling him to come over to the Roman Catholic religion, the lord chancellor is empowered to order the parent to make a proper allowance (11 and 12 Wm. III., c. 4); and if Jewish parents refuse to allow their Protestant children a maintenance suitable to the parent's fortune and the age and education of the children, the lord chancellor, on complaint being made, may make such order as he shall think proper (1 Anne, st. i., c. 30).

Parents are not bound to make any provision for their children after their death. Every man, and every woman who is capable of disposing of her property by will, may dispose of it as they please; except a freeman of London, who is under some limitations as to the power of disposing of his personalty by will, which limitations are in favour of his wife and children. A parent or child may aid each other in a law suit by paying fees, without being guilty of maintenance, if they have no expectation of repayment.

Parents are not legally bound to give any education to their children, nor are they under any restrictions as to the kind of education which they may give. Certain penalties were imposed by statute (1 Jac. I., c. 4; 3 Jac. I., c. 5) on a person who sent a child under his government beyond seas, either to prevent his good education in England or for the purpose of placing him in a Popish college or being instructed in the Popish religion; and further penalties and disabilities were imposed both on the person sending and the person sent, by the 3 Car. I., c. 2. It seems that it was intended to repeal these penal and disabling statutes by the 31 Geo. III., c. 32, in favour of any Roman Catholic who took the oath therein prescribed; and probably these statutes may be considered as repealed.

The power of a parent over his children continues until the age of twenty-one, when they are emancipated; and if a parent die leaving a child under age, he may appoint a guardian to such child till the age of twenty-one, by a will executed pursuant to 1 Vic., c. 26. A mother has no power over her children. A person under age, except a widower or widow, cannot marry without the father's consent, or such consent as is required by the Marriage Act. [**Marriage**, p. 441.]

A child under age may acquire property by gift; and if a father is the trustee of his child's estate, he must account to the child when he comes of age, like any other trustee. So long as a child who is under age lives with and is supported by the father, the father is entitled to receive the reward of the child's labour. When a child has a fortune of his own, and the father is not able to maintain him suitably to such fortune, a court of equity will allow the father a competent sum for maintenance out of the child's estate; but a father is not entitled to any such allowance in respect of costs incurred by him for his child's maintenance before he obtains such order of court for maintenance.

A parent may maintain an action for the seduction of a daughter on the ground of loss of her services, if there is evidence of her acting in the capacity of servant, or living with the parent in such a manner that the parent had a right to her services. This action has been maintained by a father in the case of his daughter, a married woman above age, living separate from her husband, and with the father; and by an aunt for the seduction of a niece living with her, to whom she stood in the relation of parent. The foundation of the right to maintain such an action is the loss of the services to which the parent is entitled. In allowing such an action therefore in the case of a child above age or a married woman, the courts have departed from the legal principle which is the foundation of the right of action.

A father is legally entitled to the care and custody of his children, but he may be deprived of the care of them by the court of chancery, if his conduct is such as, in the opinion of the court, endangers the morals of the children. Percy Bysshe Shelley was, among other things, restrained by an order of the court of chancery from taking possession of the persons of his infant children, on the ground of his professing irreligious and immoral principles and acting on them. W. P. T. L. Wellesley was also restrained by a like order from removing his children from the care and custody of their aunts, on the ground of his immoral conduct, and directions were given by the court for the custody and education of the children. But, except in such cases as these, the children cannot be taken from the care of the father and given into the custody of the mother or any other person.

Under a recent act (2 and 3 Vic., c. 54) a mother who is living apart from her husband may obtain by petition an order from a court of equity for access to her child while in the sole custody of the father, or of any person by his authority, or of any guardian after the death of the father, subject to such regulations as the judge may think convenient and just; and if such child shall be within the age of seven years, the judge may order the child to be delivered into the custody of the mother until the child attains the age of seven years, subject to such regulations as aforesaid. But no mother is to have the benefit of the act against whom adultery has been established by judgment in an action at law, or by the sentence of an ecclesiastical court.

The relations between parent and child which are not founded upon the parental power, but arise in respect of gifts by the parent to the child on marriage or any other occasion, and in respect of purchases by the parent in the name of the child, belong to various heads or titles of the law of property, inasmuch as the rights and claims of other persons besides parent and child are involved in such cases.

A child who is under the parental power owes obedience to his parent, which the parent may enforce by his superior strength, provided he uses it with moderation. He may beat his child and restrain his liberty, but not in such a way as to injure his health. A child is legally bound to maintain his indigent father and grandfather, mother and grandmother, if he is able; the penalty in case of refusal is 20*s.* per month.

The Paternal Power (patria potestas) among the Romans was a peculiar feature in their institutions. It was founded on a legal marriage, or on a legal adoption: the children of such marriage and such adopted children were in the power of the father; the mother had no power over the children. It followed from the principle of the patria potestas, which involved a right of property, that the children of a son, not emancipated, were also in the power of their grandfather. By the death of the grandfather the son became *sui juris*, and his children and grandchildren fell into his power. The patria potestas could also be dissolved by **Emancipation**. Originally the father's power was absolute over the child, who had no independent political existence, at least as a member of his father's family. He was a Roman citizen, but at home he was subject to the domestic tribunal. Within the family the father had a power of life and death, and could sell the son as a res mancipi, either by way of punishment, or by way of dissolving the family connexion. [**Emancipation**.] The father also originally possessed the jus noxae dandi with respect to his son as well as a slave, a power which was a consequence of the principle of the father being answerable for the delicts of his son, and continued as long as that principle was in full vigour. The son who was in the power of his father could acquire no property for himself; all his acquisitions, like those of a slave, belonged to his father; but at the death of the father they might become his own property, a circumstance which distinguished the acquisitions of a son from those of a slave. The father could marry his children, divorce them, them in adoption, and emancipate them at pleasure.

The strict notion of the patria potestas lies at the foundation of the Roman polity. Like other institutions however, which in the early history of a state form its essential element, the strict character of the patria potestas became gradually relaxed and greatly changed. The history of such changes is a part of the history of Rome.

The patria potestas might be dissolved in other ways besides those mentioned. If a father or son lost his citizenship, the relation between them ceased, for this relationship could only exist between Roman citizens. If father or son was made a prisoner by an enemy, the relation was in abeyance (in suspenso), but was not extinct. If the son attained certain high offices in the state, either civil or religious, the patria potestas was thereupon dissolved.

(Gaius, i. 55, 97, 127, &c.; Marezoll, *Lehrbuch der Institutionen des Röm. Rechtes*, 1839; Savigny, *System des heutigen Röm. Rechts*, 1840.)

PARGA, a town in the province of Albania in European Turkey, on the coast of the Ionian Sea, opposite to the Isle of Paxo, from which it is 12 miles distant, in 39° 17′ N. lat. and 20° 19′ E. long. This place is first mentioned in the fourteenth century, when, amidst the wreck of the Eastern empire, the inhabitants of Parga sought safety in the protection of Venice, and became voluntary subjects of that republic. A nobleman of Corfu, under the title of governor, resided at Parga, subject to the Venetian governor-general at Corfu, and commanded the garrison, which consisted of a company of Sclavonian or Italian troops, in the pay of Venice. The Parguinotes however had their own municipal council, which appointed the magistrates, and they enjoyed several other privileges. They were all armed, and were frequently at war with their neighbours. This state of things lasted till the fall of Venice, in 1797, when, in the partition of the Venetian territories between France and Austria, France got for herself the Ionian Islands and the Venetian settlements on the coast of Epirus. These settlements were Butrinto, Parga, Prevesa, and Vonitza in the Ambracian Gulf. They had each a small territory, which was guaranteed from Turkish intrusion by treaties between the Porte and Venice. The French, having taken possession of the Ionian Islands, sent small garrisons to each of these towns to replace the Venetian garrisons. But the invasion of Egypt by Bonaparte, in time of profound peace with the Porte, threw the latter into the coalition then forming against France; and a treaty was concluded in December, 1798, between Russia and Turkey, by which the two powers agreed to join their forces by sea and by land against the common enemy. The Turco-Russian fleet and army accordingly attacked the Ionian Islands, and took them from the French, and at the same time Ali Pasha of Epirus attacked the French garrison of Prevesa, and massacred it with circumstances of great atrocity. He likewise invaded Butrinto and Vonitza, from which the French had withdrawn, as well as from Parga. Parga however was strong by nature, and the inhabitants, being summoned by Ali to surrender, boldly refused. In March, 1800, a convention was agreed upon between Russia and Turkey, by which the Ionian Islands were constituted a republic, under the suzerainty of the Porte and the guarantee of Russia. By article viii., of the same convention it was stipulated that 'the former Venetian possessions of Butrinto, Prevesa, Parga, and Vonitza, which are on the continent and contiguous to Albania, shall belong in future to the Porte, and the inhabitants of these places be governed by a Turkish commandant, paying however no more tribute than they used to pay to Venice; the inhabitants shall continue to be administered according to their own laws and customs, shall retain the free exercise of their religion, and no Mussulman shall acquire property or reside amongst them, with the exception of the commandant.' By article ix. of the same convention the emperor of Russia promised to use his endeavours, in the event of a general peace, to cause the stipulations of the present treaty to be accepted by the other powers. (Martens, *Recueil de Traités*, vol. vii.) To the unfortunate surviving people of Butrinto, Prevesa, and Vonitza, who were already in the grasp of Ali Pasha, who had treated them with great cruelty, this convention was a boon, by giving them a claim to some sort of protection. Parga however was still free, and the inhabitants for a time refused to submit, but being threatened with imminent destruction from the numerous forces of Ali Pasha, they sent a deputy to Constantinople to request the protection of the Porte, and through the influence of the minister of the republic of the Ionian Islands, supported by Russian influence, the divan sent them a bey to reside among them, thus fulfilling the stipulations of the treaty, and at the same time protecting them against any encroachments from Ali. Parga remained in this state of nominal subjection to the Porte till 1806, when war broke out between Russia and the Porte. Ali Pasha took this opportunity of taking military possession of Prevesa, Butrinto, and Vonitza, and dealing with the inhabitants as he pleased, against the stipulations of the convention of 1800. Those of Parga, fearing the same fate, applied for protection to the Russian admiral on that station, who sent them a garrison.

By the treaty of Tilsit, in 1807, the Ionian Islands being given up to France, the Russian troops which were stationed in them withdrew, including the detachment at Parga. Ali Pasha now renewed his efforts to take possession of Parga, and applied to the French governor-general at Corfu for the formal cession of that place. That officer however refused, and sent a garrison to Parga. In 1814, the English, having already driven the French out of the Ionian Islands, with the exception of Corfu, and placed a garrison in the island of Paxo, which lies in sight of Parga, Ali Pasha sent a considerable force against Parga, which invaded its territory, took some villages, and murdered or carried away the inhabitants, but the Parguinotes sallied out of their town, repulsed the Turks, and killed the bey, who was a nephew of Ali. The French garrison remained within the citadel, and did not take part in the action. The Parguinotes, seeing that they could no longer rely on the protection of France, applied to the English at Paxo, in March, 1814, and offered to hoist the English flag, and master the French garrison, if the English would take them under their protection. General Campbell, who commanded in the Ionian Islands, sent a detachment with two frigates, and the Parguinotes having surprised the citadel and hoisted the English flag, the detachment was landed, and took possession of the fortress on the 22nd of March, and the French garrison was sent to Corfu. (Colonel de Bosset, *Proceedings in Parga, with a Series of Correspondence and other Documents.*)

The future condition of the Ionian Islands remained to be settled by the great powers assembled at the congress of Vienna. A convention, agreed upon between the courts of Russia, Prussia, Austria, and Great Britain was signed at Paris on the 5th of November, 1815, by which the isles of Corfu, Zante, Cefalonia, Santa Maura, Ithaca, Cerigo, and Paxo, with their dependencies, 'as designated in the treaty between his majesty the emperor of all the Russias and the Ottoman Porte, concluded on the 21st of March, 1800,' were to form an independent state under the protection of the crown of Great Britain. By article viii. of the same convention the Ottoman Porte was invited to accede to its stipulations. The Porte, being applied to, demanded as a preliminary step, the fulfilment of the treaty of March, 1800, by the formal cession of Parga. After some lapse of time, an agreement was entered into at Constantinople between the English minister and the divan early in 1817, for the delivery of Parga to the Porte, under the condition that those inhabitants who might choose to emigrate should have an asylum in the Ionian Islands, and their immoveable property be valued and paid for by the Porte previous to their embarkation. Joint commissioners were appointed, one by the English and the other by Ali Pasha, for the purpose of making the valuation. This arrangement was formally announced to the Parguinotes by a proclamation, dated 20th May, 1817. The primates and other inhabitants declared that all would leave the place rather than trust themselves to the Turks.

The population of Parga at the time was stated by the English commandant, Colonel de Bosset, at 800 families, making 5000 individuals in all. The olive-trees belonging to them amounted to about 81,000. The landed property and houses were roughly estimated by Col. de Bosset at between 450,000*l.* and 500,000*l.* The proceedings for the estimation and payment of the property were protracted for nearly two years through the cavils of the Turkish commissioner, and the intrigues of Ali Pasha, who wished to obtain Parga without paying the money. Ali tried all means to excite the inhabitants of Parga to acts of violence, by which they might forfeit the English protection, but the good sense of the Parguinotes and the steadiness of the British authorities disappointed his cunning. At last, in May, 1819, the whole population of Parga emibarked in English vessels, having received the valued amount of their property, 150,000*l*., and were settled at Paxo and Corfu. The Turks then occupied Parga. (*Letter from a Grecian Traveller respecting the intended Cession of Parga*, London, 1819.)

The cession of Parga has been treated by several writers as a question of feeling rather than one of strict diplomacy, and has been made on the Continent the topic of much declamation against England, both in prose and in verse. That cession however was a direct consequence of the treaty of March, 1800, in which England had taken no part, which treaty was the result of two unprincipled acts of aggression by Bonaparte, the first against Venice, and the second upon Egypt. In politics, as in private morality, one act of injustice is often the leader of a long train of woful results. A liberal Italian writer, Count Pecchio, in his 'Life of Foscolo,' ch. x., frankly acknowledges that the cession of Parga was obligatory upon the English in fulfilment of former treaties, and that they did everything they could to mitigate its hardships upon the inhabitants, considering that they had to deal with such a man as Ali Pasha; and Foscolo, by birth a Greek, after writing a big book on the subject, perceived his mistake just in time to stop its circulation.

The town of Parga stands on a rock forming a small peninsula. It has two ports, one of them antiently called γλυκὺς λιμὴν, 'the port of sweet waters,' now Port Veliki. The town is walled and has narrow streets. The citadel on the summit of the rock is almost impregnable. It is surrounded by a fertile territory, and the townsmen export oil, tobacco, fruit, and tolerably good wine.

PARHE'LION (παρά, by the side of, ἥλιος, the sun), a name given to the mock suns, as they have been called, which sometimes appear near the sun; being, as is supposed, images of the latter formed by reflection from a cloud.

PARIA, THE GULF OF, extends between the island of Trinidad and the continent of South America, and has received its name from the adjacent portion of the continent, which was once called Paria, a name afterwards superseded by that of Cumana. The gulf extends about a hundred miles, from 61° 30′ to 63° W. long. It has nearly the form of a quadrangle, whose longest side lies east-north-east by east and west-south-west by west, and is about 30 miles across.

A hilly promontory, projecting from the continent of South America more than 70 miles, separates the gulf from the Caribbean Sea, and terminates on the east with Cape Punta de la Peña, which is also called Cape Paria. Opposite this cape and about 20 miles from it is the most north-western point of the island of Trinidad. This opening contains four straits formed by three rocky intervening islands. The most western of these straits, called Boca de Dragon (Dragon's Mouth), is the widest, and about 6 miles across. There are several rocky islands in it towards the Punta de la Peña, but as all of them are above the water, they are easily avoided. The rocky island east of it is called Chacachacares. Between it and the Isla de Huevos (Isle of Eggs) is the second strait, called Ship Channel, which is only two miles wide. This channel, which bends south-eastward, is used by vessels leaving the gulf, but not generally by those that enter it, as the current sets outward and is strong. Between the Isla de Huevos and the Isla de Monos (Isle of Apes) is the Huevo Channel, which is somewhat wider than the preceding, and is more used by vessels entering than leaving the gulf. The Monos Channel, between the Isla de Monos and the north-western point of Trinidad, is the narrowest, and the current in it is the strongest. It is only navigated by small vessels. As the current runs through all these straits northward, the gulf can only be entered with a strong breeze.

The southern entry of the gulf is between the rocky cape called Punta Icacos, in the island of Trinidad, and the low alluvial shores lying on both sides of the two most western of the mouths of the Orinoco, called Cano de Pedernales and Cano de Manamo Grande. From these low shores a shoal extends nearly across the strait, which is called the Serpent's Mouth. Less than half a mile from Trinidad this shoal is dry at low water, and called the Isla de Soldado. Between this island and Trinidad is the narrow entry into the gulf, which can only be passed with a strong south-west wind.

The gulf itself may be considered as one of the most extensive and best harbours in the globe. It offers nearly everywhere excellent anchorage, especially along the coasts of the island of Trinidad. Its depth, except near the shores, varies between 8 and 30 fathoms, and the ground is everywhere free of rocks. It is only along the south-western coast that there are sandy shoals, which have from 3 to 5 fathoms water on them. The water is as salt as that of the Atlantic, though it receives a great volume of fresh water by those mouths of the Orinoco which fall into it and by the river Guarapiche, which enters it not far from its western extremity. It is supposed that the current which sets through the gulf in a northern direction is caused by the waters of the Orinoco. The tides also, which rise about six feet, run with great force.

(Depons, *Voyage à la Partie Orientale de la Terre Ferme, &c.*; Lavaysse's *Description of Venezuela, Trinidad, Margarita, and Tobago.*)

PARIAN CHRONICLE is the name given to a block of marble preserved at Oxford, which contained in its perfect state a chronological account of the principal events in Grecian history during a period of 1318 years, beginning with Cecrops B.C. 1582, and ending with the archonship of Diognetus at Athens, B.C. 264. The chronicle of the last ninety years is however lost, so that the part which now remains ends at the archonship of Diotimus, B.C. 354. This chronicle was purchased at Smyrna, together with several other relics of antiquity, by Mr. William Petty, who was employed by the earl of Arundel, in the year 1624, for the purpose of making collections for him of antient works of art in Greece, Asia Minor, and the islands of the Archipelago. Gassendi states in his 'Life of Peiresc' (lib. iv., ed. of 1629), who was counsellor in the parliament of Provence, and a munificent patron of arts and learning, that the Parian Chronicle was first discovered by means of Peiresc, and was purchased for him by one Sampson, his agent at Smyrna, for fifty pieces of gold; but that when it was ready to be sent on board, Sampson was thrown into prison, and that the Chronicle was afterwards purchased for Lord Arundel, by Mr. Petty, at a much higher price. Dr. Hales, in his 'Analysis of Chronology' (vol. i. p. 103, 8vo. edition), brings forward several reasons to show the improbability of this account; but however this may be, the Chronicle reached London in 1627, and was examined, at the suggestion of Sir Robert Cotton, with great care by the learned Selden, in conjunction with Patrick Young, librarian to James I. and Charles I., and Richard James, Fellow of Corpus Christi College, Oxford. 'Many of the characters,' says Selden, 'were entirely obliterated, and many nearly so; nevertheless, by the assistance of glasses, and the critical sagacity of my very kind friend Patrick Young, after a great many repeated trials, I have restored them as well as I could.' The Chronicle was published by Selden, together with other inscriptions which were brought to England by Mr. Petty in the following year (1628), under the title of 'Marmora Arundelliana.'

During the civil war in the reign of Charles I., the Earl of Arundel removed to Antwerp, and many of the marbles which were deposited in the gardens of Arundel House were defaced and broken, or used to repair the house. The latter was the fate of the Parian Chronicle; the upper part of it, containing at least half the inscription, is said to have been worked up in repairing a chimney at Arundel House; but fortunately a copy of it was preserved in Selden's work.

In 1667 the Hon. Henry Howard, grandson of the Earl of Arundel who obtained the chronicle from Greece, presented it to the university of Oxford, where it is preserved, together with other antiquities collected by the Earl of Arundel, in a room adjoining to the public schools, called the Museum Arundelianum. The Chronicle was published again in Prideaux's 'Marmora Oxoniensia,' fol. 1676, which was reprinted in 1732, under the care of Michael Maittaire, and again in 1791, Oxford, under the care of W. Roberts. In Chandler's 'Marmora Oxoniensia,' which was published in 1763, great pains were bestowed upon the Parian Chronicle, and many parts in which the inscription was defaced were supplied by conjectures, which are frequently very ingenious and probable. It has also been published, with an English translation, in the works of Robertson, Hewlett, and H[illegible], which are mentioned in the course of this article.

The authenticity and antiquity of this Chronicle was never called in question till the latter end of the last century, when a work was published by the Rev. J. Robertson, under the title of 'The Parian Chronicle, or the Chr[illegible] of the Arundelian Marble, with a Dissertation concerning its Authenticity,' London, 1788, in which it is maintained to be a fabrication of modern times. The principal objections brought forward by Robertson are:—1, That the characters have no certain or unequivocal marks of antiquity. 2, It is not probable that the Chronicle was engraved for private use. 3, It does not appear to have been engraved by public authority. 4, The Greek and Roman writers for a long time after the date of this Chronicle complain that they had no chronological account of the affairs of ancient Greece. 5, This Chronicle is not once mentioned by any writer of antiquity. 6, Some of the facts seem to be taken from authors of a later date. 7, Parachronisms appear in some of the epochas, which we can hardly suppose a Greek chronologer in the 129th Olympiad would be likely to commit, &c.

The objections of Robertson were replied to by Mr. Hewlett, in a work entitled 'A Vindication of the Authenticity of the Parian Chronicle,' London, 1789; by Mr. Gough, in the ninth volume of the 'Archæologia;' and by Porson in the 'Monthly Review,' in 1789. His objections have been more recently noticed in the first volume of Hales's 'Chronology;' and the whole subject has been investigated with great accuracy by Boeckh, in the second volume of his 'Corpus Inscriptionum.' The authenticity of the Chronicle has been also defended by Wagner, Gött., 1790, 8vo. The result of these inquiries can leave little doubt respecting the authenticity and antiquity of the Chronicle; and the subsequent silence of classical writers respecting it, which is perhaps the strongest argument against its antiquity, may be accounted for, as Dr. Hales has remarked, by the retired and insular situation of Paros. It is written in pure and classical Greek; the characters bear several marks of antiquity; and none of the passages adduced by Robertson to prove that parts of it were taken from writers of a later date are sufficient to establish the fact. Mr. Robertson supposes 'that it must have been a spurious fabrication of some learned Greek as late as the sixteenth century, executed from a mercenary motive of gain, in order that it might be sold for a high price at Smyrna, a commodious emporium for such rarities, after he had artfully broken the block, and defaced the inscription in several places, in order to give it an air of antiquity.' This supposition however is very improbable. The inscription could not have been engraved without great trouble and expense; and the events it relates show a greater acquaintance on the part of the engraver, or the person under whose direction it was engraved, with the history of the civilization and literature of Greece, than we can suppose to have been possessed by any Greek in the sixteenth century.

The marble on which the Chronicle was engraved was five inches thick, and measured, when Selden viewed it, 3 feet 7 inches by 2 feet 7 inches; but one corner had been broken off. It contained at that time 93 lines, reckoning the imperfect ones, and might originally perhaps have contained a hundred. Upon an average the lines consist of 130 letters, all capitals, in close continuation, and unbroken into words. The events which it records are not so much those which relate to the history of the different states of Greece, but rather such as serve to illustrate the history of the civilization and literature of Greece. Thus we do not find one event in the Peloponnesian war either mentioned or alluded to, but we have an account of the establishment of the principal religious festivals, of the introduction of the different kinds of music into these festivals, of the origin of tragedy and comedy, and of the time in which the most eminent poets and philosophers lived. But as a few extracts from the Chronicle will give a better idea of its nature and contents than any description could impart, we subjoin a literal translation of two different parts, the former taken from the beginning, and the latter from the middle of it. The words and letters in brackets are a translation of those Greek words and letters which are supplied by the conjectures of Selden and Chandler, but are effaced in the original.

'I have described pr[eceding] times, begin[n]ing from Cecrops, the first who reigned at Athens, to [Ast]yanax, archon in Paros, and Diognetus at Athens.

1. 'Since Cecrops reigned at Athens, and the country was called Cecropia, before called Actice, from Actæus, a native autochthon, 1318 years.

2. 'Since Deucalion reigned by the side of Parnassus [illegible] in Lycoreia, Cecrops [rei]gn[ing] at Athens, 1310 years.

3. 'Since the cause was tried at Athen[s be]tween Ares and Poseidon concerning Halirrhothius the son of Poseidon, and the place was called Areopagus (Ἄρειος πάγος), 1268 years, Cr[anau]s reigning at Athens.

4. 'Since the deluge happened in the time of Deucalion, and Deucalion escaped the rains, [and went] from Lycoreia to Athens, to [Crana]o, and bu[i]lt the temp[le of Zeu]s [Olympios and] offered sacrifices for his preservation, 1265 years, Cra[n]a[u]s reigning at Athens.

5. 'S[ince Amph]ictyon, the son of Deucalion, reigned in Thermopylæ, and assembled the people inhabiting that district, and [call]ed them Amphictyones, and [the place of meeting P]ylæa], wh[ere] now also the Amphictyones still sacrifice, 1258 years, Amphictyon reigning at Athens.

6. 'Since Hellen the son of Deu[calion], reigned in [Phthi]otis, and they were [na]med Hellenes, who before were called Graikoi, and [they established] the Panathe[naean] games (ἀγῶν), 1257 years, Amphictyon reigning at Athens.'

52. 'Since Xerxes formed a bridge of boats on the Hellespont, and dug through Athos, and the battle was fought at Thermo[py]læ, and the sea-fight by the Greeks at Salamis against the Persians, in which the Greeks were victorious, 217 years, Calliades being archon at Athens.

53. 'Since the battle at [P]latæa was fought by the Athenians against Mardonius, the general of Xerxes, in which the Athenians conquered, and Mardonius died in the battle, and the fire flowed [in Sic]ily around Ætna [2]16 years, Xantippus being archon at Athens.

54. 'Since [Ge]lon, the son of Deinomenes, became tyrant [of Syracuse], 215 years, Timosthen[es] being archon at Athens.

55. 'Since Simonides, the son of Leoprepes, the Cean, who invented the art of memory, got the prize at Athens teaching [a chorus], and the statues of Harmodius and Aristogeiton were erected, 2[14] years, [A]dimantus being archon at Athens.

56. 'Since Hiero was tyrant of Syracuse, 20[8] years, Ch[ar]es being archon at Athens. Epicharmus, the poet, also lived at this time.

57. 'Since Sophocles, the son of Sophillus, who was of Colonos, gained the victory in tragedy, being 28 years of age, 206 years, Apsephion being archon at Athens.

58. 'Since the stone fell in Ægos Potami, and Simonides, the poet, died, having lived 90 years, 205 years, Theagenides being archon at Athens.

59. 'Since Alexander died, and his son Pe[r]diccas reigned over the Macedonians, 19[8] years, Euthippus being archon at Athens.

60. 'Since Æschylus, the poet, having lived 69 years, died at [Gel]a in [Si]cily, 193 years, Call[i]as the First being archon at Athens.

61. 'Since Euripides, being 43 years of age, first gained the victory in tragedy, 17[9] years, Diph[ilus] being archon at Athens. But Socrates and [Ana]xagoras lived in the time of Euripides.'

The preceding extracts are sufficient to give a general idea of the nature and contents of the Chronicle. For an examination of the dates which are assigned to the different events it records, the reader is referred to the first volume of Hales's 'Analysis of Chronology.'

PARIAS. [HINDUSTAN, vol. xii., p. 232.]

PARIETAL BONES. [SKELETON.]

PARIME MOUNTAINS, THE, are an extensive system of mountains in South America, which spread over the surface of English, Dutch, and French Guyana, and also over a great part of the eastern portion of the republic of Venezuela and the north-east districts of the empire of Brazil. In length they extend nearly 1200 miles, between 51° and 68° 30′ W. long. Their width varies between 140 and 450 miles, between the parallels of 1° and 8° N. lat. According to a rough calculation, this mountain-system covers a surface of about 400,000 square miles. The mountains are separated from the shores of the Atlantic by a low and flat country varying in width between 30 and 70 miles. The river Orinoco runs along the western and partly also along the northern base of the mountains.

The term mountain-system cannot properly be applied to this region. So far as it is known, it is only a huge mass of rocks, which gradually rise higher as they advance southward, until their general level attains an elevation of from 1500 to 2000 feet. The surface of this rising ground extends in many parts in level or in nearly level plains of some extent, but in others it is greatly diversified by hills, either isolated or forming ridges several miles long, and by short valleys or depressions. Few of the hills and ridges rise more than some hundred feet, and a very few summits attain more than 1000 feet above their base. The country along the watercourses is thickly wooded, as well as the greater part of the country between them, but many of the level tracts are savannahs without trees, or only covered with low bushes, which however display a great luxuriance of vegetation. Such is the nature of this region as far south as 2° N. lat. east of 58° W. long., but only as far south as 4° N. lat. west of 58° W. long.

West of 58° W. long. and near 4° N. lat. a continuous range begins, which runs westward to 64° W. long. nearly under the same parallel, and west of 64° W. long. inclines more to the south, so that at its termination near 66° W. long. it reaches nearly to 3° N. lat. This range is called Sierra Pacaraima. In its eastern part it rises from 1500 to 2000 feet above its base, and from 3000 to 4000 feet above the sea-level. Farther west it rises several thousand feet above the sea, and terminates with the Cerro Maraguaca and Cerro Duida, whose summits attain an elevation of about 10,000 feet. Along the southern base of the Sierra Pacaraima the Rio Parime runs eastward, and the Rio Tokoto westward, and by their junction near 60° W. long., the Rio Branco, an affluent of the Amazonas, is formed. The two branches of the Rio Branco drain an extensive valley, which is enclosed on the south by another ridge of less elevation.

East of 58° W. long., the highest part of the mountain-region, which is called on our maps Serra de Acaray, seems to lie between 1° and 2° N. lat. But we are entirely unacquainted with its extent and elevation. At its eastern extremity several ridges branch off northward, which traverse the French colony of Cayenne, and render its surface more mountainous than the territories of Dutch and British Guyana. [GUYANA.]

The Serra Acaray is not connected with the Sierra Pacaraima by a ridge. There is a break between them in the mountain-region, which is occupied by the wide valley in which the river Rupunoony runs eastward to the Essequibo and the Rio Tokoto westward to the Rio Branco. Where the two rivers approach near to one another (near 3° 30′ N. lat.), they are separated by a low level tract. This tract contains a lake called Amucu, which in the dry season is small, but at the end of the rainy season inundates the adjacent country to a considerable extent. A portion of the accumulated water finds its way to the Rupunoony; the remainder is carried by the Rio Pirarara to the Tokoto. At this time small canoes may pass from the Rupunoony to the Rio Branco. In the dry season the waters of the lake are only discharged into the Tokoto by the Rio Pirarara.

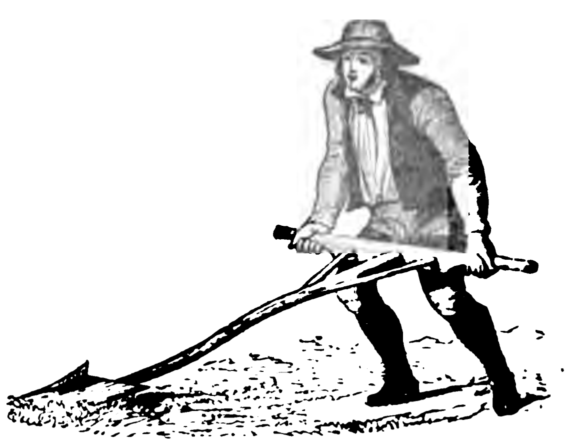
This mountain-region does not contain wide and extensive valleys in which rivers flow over a gently inclined slope, but only rocky masses through which the waters have forced their way in a deeply excavated bed between rocky banks of several feet elevation. Accordingly all the rivers of this region are nearly an uninterrupted succession of rapids and cataracts, which render their navigation very difficult, and the transport of heavy goods nearly impossible. It is only in the lower part of their course, where they run through the level country which separates the mountain region from the sea, that there are no impediments to navigation.

(Humboldt's *Personal Narrative;* Schomburgk, in *London Geographical Journal*, VI. and VII.)

PARING AND BURNING. This operation consists in cutting a thin slice from the surface of land which is overgrown with grass, heath, fern, or any other plants which form a sward by the matting together of their roots. The sods are allowed to dry in the sun to a certain degree, after which they are arranged in heaps, and burnt slowly, without flame or violent heat. The result is a mixture of burnt earth, charred vegetable fibre, and the ashes of that part which is entirely consumed.

The object of this operation is twofold: first, to kill insects and destroy useless or noxious weeds completely; and secondly, to obtain a powerful manure, impregnated with alkaline salts and carbonaceous matter, which experience has shown to be a very powerful promoter of vegetation.

The instruments by which this is effected are, either a common plough with a very flat share, which may be used when the surface is very level without being encumbered stones or large roots, as in low moist meadows, or in other cases a paring-iron used by hand. (See *fig.*) The



crossbar of this instrument is held with both hands; and the upper parts of the thighs, being protected by two small slips of board, push the instrument into the ground, so as to cut a slice of the required thickness, which is then turned over by moving the cross-handle. The labour is severe, and a good workman can scarcely pare more than one-sixth of an acre in a day. The price of this work is from 15s. to 25s. per acre, according to the price of labour. The drying, burning, and spreading of the ashes are contracted for from 10s. to 15s. more: thus the whole cost is from 25s. to 2l. per acre. In France it is done by a *cob*, which is like a shipwright's adze, and the operation is called *écobuer*.

Paring and burning the surface is an almost invariable preliminary in the converting of waste lands to tillage; and where these lands are in a state of nature, overrun with wild plants which cannot be easily brought to decay by simply burying them in the ground, burning is the readiest and most effectual mode of destroying them. In this case the practice is universally recommended and approved of.

But it is not only in the reclaiming of waste lands, and bringing them into cultivation, that paring and burning the surface is practised. The fertility produced by the ashes, which is proved by the luxuriance of the vegetation in the first crop, has induced many to repeat this process so often, as materially to exhaust the soil, and induce partial sterility. Hence the practice has been recommended on the one hand, and strongly reprobated on the other.

When we come to apply to the subject the test of experience, and reason correctly on the facts which are presented to us by the abettors of the practice and its adversaries, we shall find that the advantages and disadvantages arise chiefly from the circumstances under which the operation is carried on. But it may be necessary to an impartial examination of the subject, to inquire into the changes produced on the substances subjected to the process of burning, when it is done with due precautions.

In burning vegetable matter in an open fire, the whole of the carbon is converted into carbonic acid and flies off, leaving only some light ashes containing the earthy matter and the salts which the fire could not dissipate. These are no doubt very powerful agents in promoting vegetation, when they are added to any soil: but they are obtained at a very great expense of vegetable matter, which, by its decomposition in the earth, might also have afforded food for vegetation. If the earth which is burnt with the sods is of a cold clay nature, the fire will change it into a kind of sand, or brick dust, which is insoluble in water, and corrects the too great tenacity of clays, by converting them more or less into loam. This is so well known, that clay is often dug out of the subsoil to be partially burnt. On stiff clay soils therefore there is a double advantage in paring and burning, that of the vegetable ashes and of the burnt clay. When the fire is so managed that the vegetable matter is only partially burnt, the oily and inflammable portions being converted into vapour by the fire without being destroyed, and absorbed by the earth, the effect produced is only to impregnate the earth with minute particles of matter, readily converted into the constituent parts of vegetables. The earth is the mere recipient of these particles, which are held in its pores, as water is in a sponge, ready to be let loose to any substance which has the power of attracting them. The moisture, which the dry earth will also absorb from the atmosphere if rain should fall, is retained and increased by the effect of salts with which it is impregnated. It is uniformly observed that turnip-seed, which in most soils will not vegetate without heavy dews or rains, if sown in dry weather, scarcely ever fails to spring up in the ashes of a soil that has been pared and burnt. May not this be ascribed to these particles, which have been taken up by the earth in the operation of slow combustion, absorbing moisture from the air, and giving it out to the seed which has been sown? It does this better than a heavy shower would: a heavy shower soaks the ground for a short time, and swells the seed; but, if it be succeeded by a hot sun, the water evaporates so rapidly, that the seed loses its moisture, and vegetation stops. The earth, which attracts moisture from the air, keeps it, its absorbent nature preventing the evaporation; and it furnishes it gradually to the vegetating seed as it is required. The wonderful effect of peat-ashes on young clover may be explained on the same principle, and probably also that of gypsum. There can be no doubt then, that considerable advantages may result from the operation of paring and burning the surface of clays. But what is lost and destroyed in the operation? All that escapes in the shape of gas or vapour. The gas will probably be carbonic acid; for this is formed by the combustion of charcoal. We know that hot lime has a very strong attraction for this substance, which it fixes in a solid state, becoming a carbonate of lime: and we have no reason to think that it parts with it to the roots of plants. But other earths may absorb carbonic acid without having so great an attraction for it, and let it loose to water, with which it is known to combine in certain proportions, and to be thus carried into the vessels of growing plants by the suction of the roots. If this should prove to be the case, we may account for the great effect of burnt soils in promoting vegetation.

The principal objection to burning is, that it destroys a great portion of vegetable matter. But this is a fact to be proved, and is perhaps rashly taken for granted. When vegetable matter decays in the earth, it loses much of its substance, which is converted into volatile matter, and flies off into the atmosphere. It is possible that thus more is lost during the time that the slow decay goes on, than even in burning with due precautions. This is a fact which it may be difficult to ascertain; but it is not impossible; and therefore the assumption of the contrary requires to be founded on some proof or experiment. The earthy portion of the soil may be diminished, by driving out the water which it holds, as is manifest in burning clay, and it shrinks into a smaller space; but there is as much earthy substance as before, and this substance is improved by the burning. It appears then, that a clay soil may be pared and burnt, without its real substance being diminished; and if its texture is improved, it becomes more fertile by the operation.

Burning clay soils is in fact something analogous to liming. Lime dissolves the vegetable matter, and enables the elements to enter into new combinations; but if no new vegetable matter be added to restore what is exhausted by vegetation, liming, as well as paring and burning, is detrimental to the soil. Many experienced farmers pare and burn the sod on the edges of their ditches and on the banks on which the hedges grow, because they thereby exterminate many rank weeds; and the burnt earth mixed with farmyard dung makes an admirable compost. Here the burnt earth acts as an absorbent, and no doubt attracts many of the volatile parts of the manure, which are produced by the decomposition of animal and vegetable matter in it. Paring and burning therefore should be joined to manuring, if a powerful and immediate effect is desired without exhausting the soil; and in this case we do not hesitate to recommend it on all cold clay soils where rank weeds are apt to spring up and coarse grasses take the place of the better sorts which have been sown. The proper time to pare and burn is evidently after the land has lain in grass for several years, and is broken up for tillage. The surface should be pared thin; about two inches is the extreme thickness allowable for the sod if the soil is very stiff and poor, and as thin as possible in a better soil. It should be pared with a breast-plough or paring iron by manual labour. The sods should be moderately dried, and then arranged in small heaps with a hollow in the middle to hold heath or faggots to kindle the fire. When it has fairly established itself, all the apertures should be carefully closed. Wherever any smoke breaks out, a fresh sod should be immediately put over it; a heap containing a small cart-load of sods should be smouldering for several days without going out, even if it rains hard. If the fire is too brisk, the earth will form hard lumps, and even vitrify; but otherwise it comes out in the form of a fine powder, in which evident marks of charcoal appear. If this is of a fine red colour, it is a good sign; for the iron in the earth has been converted into a peroxide, which is perfectly innocent in its effects on vegetation, whereas all the saline impregnations of iron are more or less hurtful. It is better to burn the sods in large than in small heaps; for the more the fire is smothered, the better the ashes.

So great a quantity of ashes is sometimes produced as to admit of a portion being carried off on grassland, or used to manure another field for turnips. As this is evidently robbing the field where the operation has been carried on, an equivalent quantity of manure should be brought in exchange. Perhaps the most advantageous mode of using the ashes is to spread them in the drills where the turnip-seed is to be sown, after a portion of dung has been buried under them. In this manner the ashes from one acre of land pared and burnt, together with ten or twelve cart-loads of good yard dung, will manure two acres, and all the manure of one acre, in the ordinary mode of raising turnips on ridges, will be saved. If the ashes will produce as good turnips with half the usual quantity of dung, the expense of paring and burning is amply repaid. But experience proves that the earth and ashes almost ensure a good crop of turnips in many poor stiff soils in which they would probably not have succeeded if sown in the common course of cultivation without bones or ashes.

When a considerable extent of poor land is brought into cultivation, and there is no sufficient supply of manure at hand, paring and burning a portion of the land every year, by which a crop of turnips is obtained, is a most effectual means of improvement. Lime may be used at the same time with the ashes, and will increase their effect, provided some vegetable undecayed matter remains in the soil after paring; but lime will tend to exhaust this; and if, in consequence of liming, a few good crops of corn are obtained at first, the soil will be so exhausted as to be of little value afterwards. This is the abuse of the practice, which has caused it to come into disrepute. It would be a great waste to burn the surface of a rich piece of grassland where the plants growing in it are tender and succulent, and would readily rot on being ploughed under; in such case a moderate application of lime would have a much better effect. This kind of land will produce good crops without any manure, and continue fertile for many years if judiciously cultivated. To pare and burn rich land is wasteful, and can never be recommended. It is only on poor land which has not strength to produce a crop, and of which the texture requires to be improved and its powers stimulated, that paring and burning is advantageous; on poor thin chalky soils which have been laid down with sainfoin, of which the roots and stems are grown coarse and hard, so as not readily to rot in the ground, the operation is proper and advantageous. The turnips produced by the ashes, with or without the assistance of dung, must be fed off by sheep folding on the land, whose dung and urine will enrich it, and their tread consolidate it. By this mode of proceeding great advantages are obtained from paring and burning, and the land, so far from being deteriorated, will be improved.

Many landlords rigidly forbid their tenants to pare and burn any part of their land, from an idea that the heart of it is destroyed by the burning. If they would only insist on a certain quantity of dung being put on, either at the same time that the land is thus treated, or for the next crop, and prohibit the sowing of corn crops except after turnips, clover, or some other green crop consumed on the farm, there would be little danger of any detriment to the land, even if it were pared and burnt once in every ten or twelve years, provided it were judiciously treated in the intervals. The farmer would be benefited in many situations, and the practice would tend to keep up the value of the farms.

In Devonshire, where the land has been pared and burnt from time immemorial, even where the soil is rich, the practice has been often resorted to without any judgment. Provided a crop of corn or potatoes was obtained at little cost, the consequences to the future state of the land were not heeded; and landlords, seeing their farms impoverished, put a stop to the practice. Thus many useful modes of cultivation have been reprobated from the abuse of them, which, properly applied, would have been advantageous to all parties.

There is no maxim more true than this: that whatever injures the landlord, injures the farmer who is not desirous of removing, and *vice versâ*; and all positive restrictions on cultivation, however necessary when there is a fear of dishonest conduct, diminish the value of a farm and lessen the rent which can be fairly afforded for it. Ignorance is often a greater destroyer of the interest of both landlord and tenant than wilful dishonesty; and the spreading of useful information amongst tenants, so that they may see their own advantage, is the surest means of improving landed property. Many tracts of waste land might be brought into cultivation by means of paring and burning, which without it would never repay the labour required. Where the soil is inclined to peat, this operation and abundant liming are the indispensable preliminaries of cultivation. The ashes and the lime will produce vegetation and food for animals. These will produce dung to supply what the vegetation abstracts, and to assist also in the further decomposition of the peaty matter, converting it into vegetable mould.

The first crop after paring and burning, as was observed before, should, if possible, be turnips, and these should be consumed on the spot; but there are exceptions to the rule. The soil may be a stiff clay of a considerable degree of natural fertility, only encumbered with rank weeds and grasses. In this case the surface is burnt to destroy these, and a crop of corn may safely be taken after the paring and burning, the land coming into a regular alternate rotation after it. For example, the next crop may be beans or tares, with a good proportion of dung; or clover may be sown with the first crop, if the ground appears fit for it. The effect of the ashes will be readily perceived in the luxuriance of the clover. Such land may be afterwards cultivated, according to its nature and quality, with the rest of the farm; or laid down to grass after a course of cleansing and ameliorating crops. Thus old wet meadows, after having been well underdrained, may be greatly improved, and either converted into arable fields or laid down again with choice grasses.

Old rough pastures may often be greatly improved by a very thin paring and burning, so as not to destroy all the roots of the grass. When the ashes are spread over the pared surface, some good grass-seeds are sown with them. The whole is well harrowed or scarified and rolled, and the grass which will spring up after this will be greatly improved, and will fully repay the expense of this simple mode of renovating it. This is the cheapest mode of improving coarse pastures, that we know, without breaking them up.

The partial paring and burning of the headlands of fields, for the purpose of mixing the ashes and burnt earth with dung in a compost, is a most excellent practice, and often superior to that of using the sods only, without burning them. These sods contain innumerable seeds of weeds, and eggs or maggots of insects, which are not destroyed by the fermentation of the heap, but on the contrary, are brought to life. The loss of a portion of vegetable matter in the burning is amply compensated by the destruction of these enemies of the future crops.

It now only remains to take notice of the soils and situations where paring and burning cannot be recommended. Wherever the soil is very loose from a great proportion of silicious sand in its composition, and is held together chiefly by the slender roots which run through it, the burning would destroy the whole of the vegetable matter; for none of the volatile parts which the fire dissipates or generates would be retained or absorbed, but would pass through the loose sand in the same way that water would. Here then would be actual destruction; and the residue would be a mere barren silicious sand, much worse and more porous than it was when held together by the roots. The only way to bring such soils into cultivation is to put clay or marl on them, and to force vegetation by means of liquid manures, chiefly the urine of animals, consolidating them by every means applicable, so that they may retain moisture, and that the manure may not be washed through by the rains. Such soils may be improved, but they are the most ungrateful of any; and it is only necessity and indefatigable industry which can make them produce any crops.

It is very easy to ascertain whether any soil will be improved, or not, by paring and burning. A few sods may be taken and exposed to heat in an iron pot closely covered over, or in a large crucible: the heat should not be so great as to produce light, but should be kept up for a considerable time, till the sods are consumed. If the ashes are red, and the whole is in a fine powder, with particles of charcoal in it the soil from which it was taken may be safely pared and burnt, especially if it forms a mud with water, and the earth is not readily deposited. But if it feels gritty, lets the water readily through, and is soon deposited when mixed with it, burning will not be advantageous. This is the evident result of the principles laid down before.

On the whole, the operation of paring and burning, when judiciously applied and properly performed, is a most excellent and cheap improvement of certain soils, and it will never diminish their fertility, if they are properly cultivated and manured, and a judicious succession of crops is adopted; but on the contrary it will improve their quality and texture, and make them more productive.

PARI'NI, GIUSEPPE, one of the best and most popular Italian poets of the eighteenth century, was born in the district of Bosisio near the lake of Pasiano, in the Milanese territory, May 22, 1729. His father, though poor, was anxious to bestow upon him a good education, and for that purpose removed to Milan. He was however obliged to seek to support himself at an early age, by copying, and it was only in the intervals of his employment that he could study the best writers, both Latin and Italian. In compliance with the wishes of his friends, he published a volume of poetry, at the age of twenty-three; which procured for him admission into the Accademia dei Transformati at Milan, and that of the Arcadians at Rome. These distinctions obtained him other patrons, and he was successively engaged as tutor in the Borromei and Serbelloni families, which office he accepted chiefly in order that he might be able to support his mother, who was now become infirm. It was in 1763 that he published the 'Mattino,' the first part of his celebrated poem 'Il Giorno;' which he had been induced to do by Count Firmian, then Austrian minister of Lombardy, who after employing him some time in editing a gazette, appointed him professor of belles-lettres in the Palatine schools (*scuole palatine*) at Milan, and, on the suppression of the Jesuits, promoted him to the professorship of eloquence at the college of the Brera. His course of lectures, which were printed, was as favourably received as were those which he afterwards gave on the fine arts; and both of them contributed materially to disseminate an improved taste. After the death of his patron Count Firmian, cabals were excited against him, and he was at one time in imminent danger of losing his appointments, owing to his refusing, for some reason or other, to compose, as he had been commissioned to do, an éloge on the empress Maria Theresa. Notwithstanding this, Leopold II. promoted him to the prefectureship of the Brera, with an increased salary. At the period of the French revolution politics began to engage his attention; he espoused doctrines that he considered favourable to the interests of society generally, and with such enthusiasm, that General Bonaparte and Saliceti caused him to be elected one of the magistrates of Milan; but being disappointed in his expectations of being able to serve his fellow-citizens, he requested permission to retire from office, and bestowed on the poor the emoluments he had derived from it. From this period he lived in retirement, poor but respected. In addition to his general ill state of health, he was obliged in his seventieth year to undergo an operation. He died August 15, 1799, and the astronomer Ordani caused a monument and bust of him to be erected in the college of the Brera.

His principal production, 'Il Giorno,' may be considered an ironical didactic poem, wherein, pretending to instruct a youth in the various duties and economy of a fashionable day, he satirises the frivolities, the follies, and vices of the idlers and triflers who constitute what is called the great world. Yet although it is relieved by many agreeable episodes, the continued strain of irony and mock solemnity becomes rather fatiguing; and though the style is elegant, it is somewhat too ornate and laboured for the subject. Besides this and his lyrical pieces, Parini also wrote some *rime piacevoli*, and other compositions of that class.

PARIS, the metropolis of France, situated on the river Seine, in 48° 50′ N. lat. and 2° 20′ E. long., about [illegible] miles in a direct line south-south-east of London; or [illegible] by the usual route, viz. 72 miles from the [illegible] office, London, to Dover; about 22 miles [illegible] Dover to Calais; and 157 miles from Calais [illegible] Beauvais, to Paris. It is in the [illegible] which it is the chief town.

Paris is mentioned by Cæsar [illegible] (*De Bell. Gall.*, vi. 3; vii. 57, [illegible] town of the Parisii, a tribe probably of the Belgic stock. In that part of the Seine which now traverses Paris were anciently five small islands, on one of which, now the island of La Cité, Lutetia stood. This island was then of smaller dimensions than at present, two smaller islands at its western extremity having been incorporated with it. Lutetia, anterior to the Roman conquest, was an unwalled place. The etymology of the name of the Parisii has been much disputed. Dulaure conjectures that it meant 'inhabitants of the frontier.' A British tribe, in the neighbourhood of the town of Hull in Yorkshire, had the same designation.

In B.C. 54, Cæsar convoked at Lutetia an assembly of the nations of Gaul. (Cæs., *De Bell. Gall.*, lib. vi. 3.) In the general rebellion of the Gallic nations the following year, Lutetia was burnt by the Gauls to prevent its falling into the hands of the Romans; but it subsequently came with the rest of Gaul into their power, and in the division of the country made by them was included in the province of Lugdunensis Quarta, or Senonia.

For the next four centuries the place is hardly noticed, except by the geographers, by whom the name is variously written; nor does it appear to have been of any importance until the later period of the Roman dominion. About A.D. 358 or 360 it took the name of the tribe to which it belonged, Parisii. It was the seat of a bishopric, perhaps as early as the middle of the third century. Lutetia was the favourite residence of Julian while he governed the provinces of Gaul with the rank of Cæsar. In or about the year 494 it was taken by the Franks under Clovis. Under the Romans the buildings connected with the town extended beyond the island to both banks of the river.

Several traces of Roman possession have been discovered at Paris, and some still remain. In the isle of La Cité, beneath the choir of the cathedral of Notre Dame, an altar of Jupiter was dug up, or rather a number of stones bearing sculptures in relief and inscriptions. These inscriptions, which belong to the reign of Tiberius Cæsar, indicate that at Lutetia the gods of the Romans and those of the Gauls were jointly worshipped. In 1784, during the erection of the Palais de Justice (courts of law), a sculptured stone more than six feet high, with figures in relief on its four sides, was discovered. On the north side of the Seine the remains of a subterranean aqueduct were discovered in forming the place or square of Louis XV. (A.D. 1763); and a basin, presumed to be connected with this aqueduct, was discovered in the garden of the Palais Royal. Remains of tombs and other sepulchral antiquities have been discovered in the Rue Vivienne, near the Palais Royal, and on the north bank opposite La Cité. Other antiquities were found at La Villette in digging the basin of the canal of the Ourcq, and at Montmartre. On the south side of the Seine there are some remains, opposite the isle of La Cité, which consist of a large vaulted hall or apartment, with another apartment opening into it, or rather forming a recess in it: the masonry of these consists of alternate courses of stone and brick, covered in some parts with stucco. Some remains of a subterranean aqueduct have been traced in different parts of its course from the village of Arcueil, five miles south of Paris, to Paris, and many antiquities were dug up in the gardens of the Luxembourg. The lower part of the tower of the church of St. Germain-des-Prés is supposed to be a remain of the original church built on that site by the Romans, and first dedicated to Sainte-Croix and St. Vincent.

Clovis, some years after the capture of Paris, fixed his residence there (A.D. 508), and was buried there (A.D. 511). It once came to one of the kingdoms into which the dominions of the Franks were divided, and was afterwards comprehended in the kingdom or district of Neustria. After A.D. 567 it ceased to be the residence of the kings of the Franks. Several of the churches and other religious establishments of Paris were founded in the reigns of the Merovingian princes.

In 845 the Northmen or Normans pillaged the city, which the inhabitants had deserted: in 856-7 they pillaged it a second time, and burnt some churches: in 861 they pillaged it a third time, and burnt some more churches. At this time they broke down 'Le grand Pont' (the great bridge) over the wider arm of the Seine on the north side of La Cité, to enable their barks to ascend higher up the river. After their retreat, the bridge was repaired by Charles le Chauve. In 885 the Normans again attacked the place. The inhabited part of Paris was still limited to the island of La Cité, which was walled. The assailants, to the number of 32,000, made several unsuccessful attacks, and at length retired on the conclusion of a treaty with the emperor Charles le Gros (A.D. 886). In A.D. 978 the emperor Othon or Otho II., at the head of 60,000 men, advanced to Paris, burnt a suburb, but was soon after attacked and put to flight by Lothaire, king of France. Under the Carlovingians, Paris was the capital of a county comprehended in the duchy of France. Hugues Capet inherited both the county and the duchy; and, upon his assumption of the crown (A.D. 987), they became part of the royal domains.

Hugues Capet, now king, continued to reside at Paris, which thus again became the capital of the Frankish, or, as it may now be termed, the French kingdom. In the reign of Louis VI. (A.D. 1108-1137), it is probable that the fortresses of Le Grand Châtelet and Le Petit Châtelet on the north and south banks of the river, at the extremities of the two bridges from La Cité to the mainland, were built; they were demolished, Le Petit Châtelet in 1782, and Le Grand Châtelet in 1802. By the same king or his successor Louis VII. the suburbs on the north and south banks were inclosed by walls, and thus incorporated with the insular part of the city. Under Philippe II. Auguste, a new wall was built, comprehending a much larger enclosure than those of former times, both on the north and south bank, and some of the principal streets were paved; but as late as the time of Louis XIII. (A.D. 1610-1643) half the streets of Paris were still destitute of pavement. Two national colleges and three hospitals were founded, two market-places were built, two aqueducts formed to convey water to the northern part of Paris, and several fountains were erected. The space enclosed by the wall of Philippe Auguste was in several parts unoccupied or was devoted to culture; but the vacancies were filled up partly by the monasteries, churches, and colleges founded by Louis IX. (St. Louis), his grandson; and entirely by the buildings erected by succeeding princes; so that in the reign of Jean II. (A.D. 1350-1364), the town had outgrown its limits, and many edifices had been erected without the walls. In apprehension of an attack from the English after the battle of Poitiers (A.D. 1356), new walls were raised on the north side of the Seine, comprehending a yet larger enclosure than those of Philippe Auguste; and on the south side the old walls were repaired and the ditches deepened. The island of Notre Dame (now of St. Louis), immediately above that of La Cité, was also fortified by a ditch dug across it.

Le prevôt des marchands (the provost of the traders) was at this time a person of considerable importance. Paris had no regular municipality, but the traders or merchants who resided there had formed themselves into an associated body (*confrérie*), on which (A.D. 1220) Philippe Auguste had conferred several privileges and a limited judicial authority. This association, which was sometimes termed *La Hanse Parisienne*, gradually came to occupy the place of a municipal body.

The treaty of Troyes (A.D. 1420) and the events connected with it gave Paris into the power of the English party, and the city remained under the government of Henry VI., king of England and claimant of the throne of France; or rather, under the government of the regent duke of Bedford, from A.D. 1421 to 1436. In 1429 it was attacked by the troops of Charles VII. of France under the command of Jeanne d'Arc, but the assailants were repulsed. In 1436 it was taken by the French under the count of Richemont, constable of France, and the count Dunois, with the aid of the townspeople. The English garrison was surprised and put to the sword, except a few who retired to the fortress of the Bastille, and surrendered upon terms.

During the troubled period of the dynasty of Valois, the edifices, public and private, of the city were gradually improving in character. The population of Paris in the latter half of the fifteenth century is supposed by Dulaure to have been about 150,000. The police of the place was wretched; and it is a manifestation of the general insecurity, that the environs and suburbs, and occasionally Paris itself, were infested with wolves, which destroyed a considerable number of the inhabitants. The state of morals was extremely bad, and the clergy and monks and nuns seem to have shared in the general corruption.

In the reign of François I. the fortifications of Paris were repaired and strengthened. In the reign of Charles IX., A.D. 1566, the circuit of the walls was partially enlarged, in order to comprehend the palace of the Tuileries, then in course of erection, by Catherine de' Medici, the queen-mother. The residence of the king was at that time at the Louvre, originally a fortress of antient date, which had been made a royal residence, and enlarged and adorned by the care of successive sovereigns. It was at this time being gradually rebuilt. The rebuilding of the suburb of St. Germain, on the south side of the river, which had been ruined in the wars of the fifteenth century, was commenced and some of its streets paved in the time of François I.; and in the reign of Henri III. a bridge was erected (near where the Pont Royal now stands) to connect the quarter of the Louvre with this suburb. This appears to have been the only bridge across the undivided stream of the Seine. There were five other bridges which connected the island of La Cité with the main. Two of these, long known as *Le Grand Pont* (on the site of the present *Pont au Change*) and *Le Petit Pont*, had existed (or rather bridges at those parts had existed) from the time of the Romans. The *Pont des Moulins* (mills' bridge), connected La Cité with the north bank of the river a little below the *Pont au Change*.

The other two bridges were the *Pont Notre Dame* and the *Pont St. Michel*. *Pont Notre Dame*, a wooden bridge, which united La Cité with the north bank, was built A.D. 1413, in the place of a former private bridge communicating with some mills on the river, and rebuilt of stone (A.D. 1500-1512): it is at present the oldest bridge in Paris. Pont St. Michel, of antient but unknown origin, was rebuilt of stone (A.D. 1378-1387), damaged and repaired repeatedly, and was entirely rebuilt in the seventeenth century. In the reign of Henri II., successor of François I. (A.D. 1549), the erection of the present Hôtel de Ville was commenced, but it was not finished till more than half a century afterward. The police of the city continued to be in a wretchedly inefficient state. The number of robbers and others engaged in lawless pursuits was estimated by a contemporary authority at 6000 to 7000: the paupers were estimated by another authority at 8000 to 9000; both of which numbers are evident exaggerations. The whole population, in the time of Henri III., is estimated to have been 200,000 or upwards.

In the religious troubles of the sixteenth century, Paris was the scene of several remarkable events. [BARTHOLOMEW, MASSACRE OF ST.] In 1588 the Parisians, who had embraced the party of the League, barricaded the streets with chains, with the paving-stones torn up for the occasion, and with casks of earth; and manning the barricades with musqueteers, defeated the troops (to the number of 6000) which Henri III. had brought into the city. Henri quitted Paris next day, and the city came entirely into the power of the League. This revolt is known in history as 'the day of the barricades.'

Upon the assassination of the Guises at Blois (December, 1588), the Parisians broke out into a fresh revolt: the duke of Aumale was chosen governor, and the direction of affairs was assumed by a committee of the League, designated 'the Council of Sixteen.' Henri III., who had effected a reconciliation with Henri of Navarre, chief of the Huguenot party, advanced to besiege Paris, which was now under the command of the duke of Mayenne, brother of the murdered Guises: but the assassination of Henri III. at St. Cloud (August 20, 1589) arrested his purpose. The siege was formed on the 31st of the following October, by his successor Henri of Navarre, now Henri IV. The suburb of St. Germain was plundered, but the siege was raised soon afterwards, and the king retired with his army. In the following May (1590) the siege was renewed, the suburbs were all taken in one night, and the gates were strictly blockaded. The effect of this measure on a population so vast was truly dreadful. The most loathsome articles were consumed for food; numbers perished, and parts of the city were almost reduced to solitude. Henri, moved with compassion, allowed 3000 of the poorer class to pass out of the place, and repeatedly admitted supplies of provisions to enter. The approach of a Spanish force under the duke of Parma obliged him to raise the siege (August 30); and he did not obtain possession of his capital till March, 1594, and then only by bribing the governor (the duke of Brissac) and other influential persons.

In the reign of Henri IV. Paris received many improvements. The Pont Neuf, which had been commenced in the reign of Henri III., was completed by Henri IV., and the two westernmost of the islands in the Seine were united to La Cité. All the bridges, except the Pont Neuf, this time lined with houses. In respect of cleanliness and security from robbery, little improvement seems to have taken place. In the reign of Louis XIII. an immense number of religious establishments were founded at Paris. The palace of the Luxembourg was built by Mary de' Medici; the Jardin des Plantes was laid out chiefly by the desire and under the direction of Labrosse, one of the king's physicians; and the Palais Royal was built and the Académie founded by Cardinal Richelieu. New walls were erected on the north-west side of the city, enclosing a considerable space north of the Tuileries and extending the circuit of the enclosure nearly to the line of the present boulevards. The island of Notre Dame, or St. Louis, was entirely covered with houses and joined to the main by two bridges. The Pont au Change was rebuilt, and a wooden bridge thrown over the river where the Pont Royal now stands. The police of the city underwent little change: disorders of every kind were of frequent occurrence. In 1621 the mob made an attack on the Huguenots who were returning from worship at Charenton, mutilated the minister, and murdered several of the bearers. [CHARENTON.]

The minority of Louis XIV. was a troubled period, and Paris was the principal scene of disorder. The enemies of Mazarin, who were known by the designation of *Frondeurs* (slingers), or collectively as the *Fronde*, were supported by the Parisians. On occasion of the imprisonment of Broussel, one of the members of the parliament of Paris (A.D. 1648), the populace rose, barricaded the streets, repulsed the French and Swiss guards, and ultimately obtained the release of Broussel. Next year new troubles broke out; the Frondeurs, in arms, occupied Paris itself; the king's troops, under the prince of Condé, occupied St. Denis, St. Cloud, and Charenton, in the vicinity. Some skirmishes took place, but peace was soon made. In 1652 the prince of Condé, who had joined the party opposed to Mazarin and the court, was with his army attacked in the suburb St. Antoine by the royal army under Turenne, and was only saved from destruction by being admitted into Paris. Tumults and intrigues still continued until the entry of the king into Paris a few months after. The city suffered so much from this unsettled state of affairs, that in 1653 it was estimated that there were in Paris 40,000 paupers.

In the long reign of Louis XIV. (1643-1715) Paris was greatly extended and improved. A great number of religious and charitable establishments were founded, and new churches and chapels built. Among the more remarkable of the charitable institutions were the immense workhouse, called L'Hôpital Général or La Salpêtrière (established A.D. 1656), and its dependency, the Bicêtre [*BICETRE*], and the hospital or asylum for old soldiers, known as the Hôtel des Invalides. Louis made considerable alterations in the Louvre, completed the building of the Tuileries, laid out anew the gardens of that palace, and formed the public walk or garden of the Champs Elysées, and the places or squares of Vendôme, of Les Victoires, and of Le Carrousel. The triumphal arches or gates of St. Denis and St. Martin and many fountains were also erected at this time; the observatory and several theatres were built, and the Pont Royal and Pont de Grammont (the last connecting the isle Louvier with the northern bank of the river) were constructed. The old and now dilapidated fortifications on the north side of the Seine were demolished, and the present line of the boulevards in that part of Paris was formed; new streets were laid out, and quays made along the banks of the river: the police of the city experienced several improvements, the streets were lighted, though in a miserably inefficient manner, and the cleanliness of the city was somewhat attended to. The population of Paris, at the close of the reign of Louis XIV., was fast approaching half a million.

The long reign of Louis XV. (A.D. 1715-1774) and the earlier part of that of Louis XVI. (A.D. 1774-1792) furnish few local incidents. The distress caused by the financial projects of Law (A.D. 1720) occasioned some tumults. The years 1727-31 were marked by the extraordinary scenes of fanaticism which first occurred at the tomb Paris, a Jansenist clergyman. [JANSENISTS.] In 1775 the bakers' shops were plundered by a mob excited by the dearness of corn.

From the commencement of the reign of Louis XV. to the period of the Revolution, Paris received considerable accessions both to its extent and the number of its public buildings. Ecclesiastical establishments continued to increase: the church of Ste. Geneviève (the Pantheon of the revolutionary period), the *Hôtel des Monnaies* (or Mint), and the *École Militaire* (Military School) were built; several places and houses in considerable number were formed; churches and theatres erected; a line of boulevards formed on the south side of the river; the Petit Pont, which unites the Cité with the south bank of the river, rebuilt; the Place Louis XV. laid out; and the erection of the Pont Louis XVI. commenced. Paris was also surrounded by a wall, comprehending a much larger area than any previous enclosure, and designed to prevent the introduction of commodities without the payment of the octroi, or local taxes.

The local history of Paris during the Revolution is in fact the history of the Revolution itself, of which it was the principal scene. In 1789 (July 14) the Bastille was taken and demolished by the Parisians. In October of the same year the king was brought from Versailles to Paris by the Parisian mob, who had gone to Versailles. On the attempt of the king to quit France (21st June, 1791) some rioting took place, and in the early part of 1792 fresh commotions occurred. On the 20th June the Tuileries were attacked by the populace, and the lives of the royal family endangered; on the 10th August that palace was again attacked, and the king's Swiss guards who defended it were slaughtered; and on the 2nd of September the mob broke into the various prisons and massacred those confined in them. The king was deposed, and the Legislative Assembly gave place to the Convention, in which the more violent of the revolutionists gradually obtained the ascendancy.

The guillotine was erected in the Place or Square of Louis XV., between the gardens of the Tuileries and the Champs Elysées, and the king himself was one of the earliest victims (21st January, 1793). In June the Girondist party in the Convention was overthrown, and the faction of the Mountain became supreme. The clubs, especially that of the Jacobins, the commune of Paris, a self-elected municipal body, and the committees of the Convention, were the sources in which the violence of the popular party was shown. 'The reign of terror' now commenced; executions took place daily in the Place Louis XV.: Charlotte Corday, the assassin of Marat, the queen Marie Antoinette, Brissot, Vergniaud, and others, the most illustrious members of the Girondist party in the Convention, *Egalité*, ex-duke of Orleans, Danton and Camille Desmoulins, Mountaineers themselves, Madame Elizabeth, sister of Louis XVI., and numerous others perished. The victims at one time amounted to fifty or sixty a-day, and occasionally exceeded that number. The ground of the place of execution was for hours after the executions wet with blood. The guillotine was shifted from the Place Louis XV. to the Place de la Bastille, and from thence to the Place du Trône, at the eastern extremity of the city, from whence it was brought back to the Place Louis XV. for the execution of Robespierre and his associates (28th July, 1794), which put an end to 'the reign of terror.' The Convention, freed from the tyranny which Robespierre had established, restricted the power of the terrible committees, abolished the commune of Paris and reduced the clubs to subordination. The Polytechnic School, the Institute, and the Bureau des Longitudes owe their establishment to the Convention. In 1795 the Parisian rabble rose repeatedly against the government, but were put down by the armed force of the forty-eight 'sections,' or wards, into which Paris had been divided. In October, 1795, this armed force itself rose against the Convention, but was completely defeated by the troops of the line at Paris, commanded nominally by Barras, but really by Bonaparte. The government of France now passed into the hands of the two legislative councils and the executive directory. In February, 1796, a new municipal government was given to Paris, or rather twelve governments, one to each of twelve districts into which it had been divided. The year 1799 was marked by another tumultuous revolution effected by Bonaparte, with the aid of the military and of a party both in the executive directory and the two legislative bodies. Bonaparte, successively first consul and emperor, became the virtual head of the nation, and under his vigorous and able government Paris enjoyed almost uninterrupted quiet till the year 1814. Under the government of Bonaparte, Paris was greatly improved.

Paris was taken 30th of March, 1814, by the allied forces under the command of Prince Schwartzenberg, who was accompanied by the allied sovereigns. A gallant defence was made by the troops of the line in garrison, supported by the national guard, and the students of the Polytechnic and Veterinary Schools. The authorities in command of the city capitulated, and on the 31st the allied sovereigns and their troops entered, amidst every mark of welcome by the people. Napoleon was dethroned and the Bourbons restored. Next year Napoleon returned (20th March), and was received by the military at Paris with general joy, but the defeat of Waterloo brought the allied English and Prussian armies, under Wellington and Blucher, before the city. The troops in garrison amounted to 40,000 or 50,000, besides national guards and volunteers, who entered into a convention (3rd July) to quit Paris and retire behind the Loire. On the 8th of July, Louis XVIII. re-entered Paris, and the Bourbon government was restored. A long interval of tranquillity followed, but in November, 1827, on the election of liberal deputies at Paris, considerable riots took place; barricades were formed, which were taken and overthrown by the gendarmerie and troops of the line. In 1830 came the Revolution of the three days (27th, 28th, and 29th of July, which overthrew the Bourbon dynasty, and established that of Orléans. In this memorable struggle above four thousand barricades were formed, and the relaying of the pavement torn up for this purpose cost 250,000 francs, or above 10,000*l.* Of the Parisians, 788 were killed and about 4500 wounded. The troops and gendarmerie appear to have lost about 75 killed and 300 wounded. They were commanded by Marshal Marmont, duke of Ragusa.

In October, 1830, a mob arose to demand the death of the ex-ministers (Polignac and his associates) then on their trial, but it was put down without difficulty. In December, fresh troubles were excited by the sentence on the ex-ministers not being capital, but these also were easily repressed. In 1832, on occasion of the funeral of General Lamarque (5th June), the republican party made a more serious attempt at insurrection. Barricades were raised, and the insurgents mastered by force or art several of the smaller posts of the military, but the troops of the line and the national guard were too strong for them, especially as the bulk of the citizens did not sympathise with the rioters. Since that period Paris has been several times troubled by commotions, though of small importance, and by repeated attempts to assassinate the king.

The limits of Paris are defined by the wall erected (for fiscal purposes) in the reign of Louis XVI.; the outline thus formed, though broken by many irregularities, approximates to an oval, having its longer diameter, from west-north-west to east-south-east, about 5 miles, and its shorter diameter 3¾ miles. The included area is about 8600 acres, or 13½ square miles. The number of barriers or entrances through this wall was 60 in 1825, but several have been walled up, and in 1830 they were reduced to 50. (*Paris and its Historical Scenes.*) Most of these 'barriers' have toll-houses attached to them, at which the octroi, or local duties on goods entering the capital, are levied. Round the wall of Paris, on the outer side, is a road, planted with fine rows of trees, forming what is termed the 'boulevards extérieurs,' or outer boulevards. The circuit of the wall and of its accompanying boulevards is rather more than 15 miles. This circuit is skirted nearly on all sides by heights, so that the site of the city is a natural hollow.

The present enclosure of the city walls comprehends several portions, which, as being without the walls demolished by Louis XIV., were designated faubourgs, or suburbs, and which still retain that name. Some villages, formerly distinct, but which had acquired, by the gradual extension of the city, the character of suburbs, are also comprehended within the present boundary, and give name to particular quarters. Of these suburbs and quarters the following are the principal:—On the west, Chaillot, adjacent to the Champs Elysées; on the north-west, the Faubourg St. Honoré and the Faubourg du Roule; on the north, the Chaussée d'Antin (one of the handsomest and most regularly built quarters in Paris), the Faubourg Montmartre, the Faubourg Poissonnière, the Faubourg St. Denis, and the Faubourg St. Martin; on the north-east, the Faubourg du Temple; on the east, the Faubourg St. Antoine: all these are on the right or north bank of the Seine. On the opposite bank, in the south-east part of the city, is the Faubourg St. Victor; on the south part are the Faubourgs St. Marcel, St. Jacques, and St. Michel; and in the south-west are the Faubourg St. Germain and the quarter of Gros Caillou. The character of suburbs now more properly belongs to the villages and hamlets which surround Paris on the outside of the wall, such as Passy (pop. 4565), on the east; Montmartre (pop. 4630) and La Villette (pop. 4999), on the north; Belleville (pop. 8179), Menilmontant, and Charonne, on the east; Montrouge (pop. 3847), on the south; Vaugirard (pop. 6695) and Grenelle (pop. 1647), on the south-west. The population of these villages is from the census of 1831.

The Seine passes through Paris in its course from the south-east to the west side of the enclosure, dividing the city into two unequal parts, that on the north side of the river being by far the larger. In the river are three islands; there were originally five, but the two westernmost have been united, as already noticed, to the adjacent island of La Cité. The island of La Cité, and that of Notre Dame, now St. Louis, are occupied by buildings; the remaining and easternmost island, that of Louvier, is occupied as a depôt for fire-wood. The banks of the river and of the islands of La Cité and St. Louis are (with one slight interruption) occupied by stone quays, furnished with parapets, and forming broad and continuous lines of street, with stone stairs at different parts. There are at different intervals wharfs or places for landing goods, termed by the French 'ports.' The river is crossed by numerous bridges, connecting the banks with each other, or with the islands, or the islands one with another. These bridges are of various materials; one is of wood; the others are of wood and iron, stone and iron, or stone, or they are chain bridges.

The Pont Neuf, which crosses the two arms of the Seine with the intermediate portion of the isle of La Cité, scarcely exceeds the new London bridge or the Southwark bridge in length, and falls considerably short of Waterloo or Westminster: the other bridges are scarcely half the length of the Pont Neuf.

The central part of the town, which is by far the oldest, has narrow and crooked streets, skirted with tall gloomy-looking houses, chiefly built of stone. The outer parts of the town are more regularly laid out. The greater part of the streets have no foot-pavement; and instead of a kennel on each side, with a raised causeway between them, as in London, there is only one kennel, in the middle of the street. In lighting, as well as in cleanliness, the streets of Paris are far behind those of London. Great improvements have however been made of late years; many 'passages' have been opened, paved with flag stones, for pedestrians only; some of the more modern streets are provided with 'trottoirs,' or foot pavements, and 'trottoirs' have been gradually extending in those of the older streets which are wide enough to admit of them. Some streets are lighted with gas; but the common mode of lighting is by lamps, supported on ropes swung across the street, between the opposite houses. The boulevards (sometimes distinguished as the boulevards intérieurs) are a line of streets, forming a circuit of smaller extent than the city wall. They indicate, on the north of the river, the line of the ramparts and ditches demolished and filled up by Louis XIV.; on the south side they are of later date, and take a wider circuit than the antient walls. They are planted throughout with alleys of trees, and the northern boulevards are the gayest thoroughfares in Paris.

The largest of the places or squares is that of Louis XV., or La Concorde; the other principal places are the Place Vendôme, the Place des Victoires and the Place du Trône (both circular), the Place du Carrousel, and the Place Royale. These 'places' are not commonly occupied by gardens, like the squares of London; but some of them are adorned with columns, statues, fountains, or other decorations. There are several public gardens and walks, as the gardens of the Tuileries, the Luxembourg, and the Palais Royal; the Champs Elysées (Elysian Fields), the Avenue de Neuilly, and the numerous avenues in the neighbourhood of the Ecole Militaire, which are streets or roads lined with alleys of trees, like the boulevards. The Champ de Mars is a very large enclosure, attached to the Ecole Militaire, and used for reviews; the Esplanade des Invalides is a garden or pleasure-ground extending from the Hôtel des Invalides to the bank of the river.

Architecture.—Philippe Auguste during his long reign (1180-1223) did much for improving and fortifying Paris: he enlarged the old château of the Louvre, first founded by Dagobert about the middle of the seventh century, and rebuilt by Louis le Gros about 1110. Yet excepting Notre Dame (commenced in the early part of the eleventh century, and whose portal or west front is supposed to have been completed in the time of Philippe Auguste, although other portions are of later date), and one or two other ecclesiastical structures, there is little even in the older parts of the city of earlier date than the reign of Francis I. (1515-1547).

Of Paris at the close of the fifteenth century the architectural physiognomy is graphically sketched by Victor Hugo, in that chapter of his 'Notre Dame' which is entitled 'Paris à vol d'oiseau.' Francis I. caused the antient Louvre to be demolished and a new palace begun from the designs of Pierre Lescot, of whose work there is now remaining that portion of the interior court which has been named the Old Louvre, in order to distinguish it from the vast additions made by Louis XIV. Still, although many of the older parts of the city date from the middle of the sixteenth century, it is hardly before the beginning of the eighteenth that Paris generally began to show itself at all in its present state. The Revolution caused the destruction or suppression of many churches and convents, some of which have since been converted to secular uses. Policy as well as ambition prompted Napoleon to endeavour to efface all traces of the revolutionary period; and most certainly Paris is greatly indebted to him not only for many embellishments and architectural monuments, but more especially for extensive plans of general improvement, and many works of public utility. The erection of spacious and convenient covered markets, of public abattoirs, or slaughter-houses, of several new bridges across the Seine, and fifteen additional public fountains, besides the formation of the Canal de l'Ourcq, for the purpose of supplying the capital more abundantly with water, are among the useful works of his reign. Again, the clearing the quays along both banks of the river from many erections that disfigured and obstructed them; the opening the noble avenue of the Rue Castiglione into the Place Vendôme; the Rue Rivoli, &c., together with the introduction of trottoirs or foot-pavements, were of very great public utility. The architectural projects first commenced by Napoleon have been since carried on with more or less vigour and spirit, and the reign of Louis Philippe has been one of great activity in that respect. The completion of the Madeleine and the Arc de l'Etoile, of the Ecole des Beaux Arts, and the Hôtel de la Quai d'Orsay, the erection of several new churches, and the extensive works now in progress both at the Palais de Justice and the Hôtel de Ville, the new halls and museums of the Louvre, and many other public works, bear testimony to the encouragement given to art by the present king of the French. Private enterprise has also done much of late years both for the embellishment and improvement of the capital; and a vast number of handsome private houses have been erected, in some places forming almost entirely new districts, and a new branch of architecture and decoration has been displayed in cafés and shops, many of which are fitted up in the most sumptuous manner. In some of them not only gilding but colouring is extensively employed, and occasionally with much taste; nor are paintings in the Pompeian style, with figures or allegorical subjects, by any means uncommon. The numerous Passages, or covered avenues of shops, similar to the Lowther Arcade in London, may likewise be reckoned among the modern improvements of the French capital; of which the Passage Colbert and one or two others possess considerable architectural beauty.

Before making a few remarks on some of the principal buildings of Paris, we shall briefly point out some of the leading characteristics of the French capital as compared with our own. The Thames at London is a nobler river than the Seine at Paris, and its bridges, though not so numerous, are greatly superior to those across the latter river. On the other hand, the quays along both banks of the Seine, lined in many parts by stately ranges of buildings, give Paris in that respect a decided superiority, the Thames being quite blocked with warehouses, or wharfs, &c., in such manner that the view from any of [illegible] bridges presents only a confused mass of mean or [illegible] erections, and even the terrace and river front of Somerset-house produce comparatively little effect. Fountains, though it must be admitted that most of them are too poor to be [illegible] embellishments, are features unknown to London, as are likewise the Boulevards and the Barriers of the French capital. These last, about sixty in number, were erected between the years 1783-9, after the designs of Ledoux. Several of these structures exhibit much originality, and picturesqueness, in their ensemble, but they also betray great want of study in regard to finish and detail. One of the most striking of them, the Barrière St. Martin (now converted into a barrack or guard-house) is a square of about 80 feet, with an octastyle portico of square columns on each of its four fronts, and above this rises a large circular mass 74 feet in diameter, surrounded below by an open arcade of twenty arches (resting upon coupled columns), and as many semicircular windows over them. Pleasing as this architectural mass is on account of its variety, it will not bear critical examination. This and one or two other barrières are given in Legrand and Landon's 'Description de Paris et de ses Edifices,' which, though it has some defects, is an interesting and convenient architectural manual.

In consequence of the changes they have undergone at different times, and of various architects having been employed upon them, the history of some of the buildings of Paris is rendered very perplexed; nor is such difficulty lessened by the repeated changes of names; for instance, what is now the Pont des Invalides was at first called the Pont de Jena, &c. In some cases too political changes have led to more than the mere alteration of names. The costly monumental chapel erected in honour of the Duc de Berri was taken down again after the July revolution, before it was actually completed, instead of being converted to some other purpose.

Travellers and tourists have generally despatched the architecture of Paris very summarily in a few random remarks on the more commonly known buildings. The older parts of the capital are almost unknown to the generality of those who visit it, although they are well worthy of being explored by the artist and antiquary; for if there be a great amount of ugliness and deformity, there is also abundance of the picturesque, together with no little variety. In this latter respect indeed Paris offers many singular contrasts, such as the Eglise de la Visitation, or the Val de Grace, and the Chapelle Expiatoire; the Tuileries, and the portico of the Chamber of Deputies; or the *Neo-Grecian* structure of the Madeleine; in short, extravagant licentiousness of taste, amounting almost to barbarism in some buildings, and scarcely amounting to pedantic affectation in others. Their admiration of the *classical* however has not induced modern French architects to adopt the Grecian orders; the small tetrastyle portico in the court of the Hôpital de la Charité, erected by Antoine about the middle of the last century, is almost the only example of Grecian Doric. It is therefore the Roman style—for the Corinthian can hardly be said to be *Greek* at all—that prevails in the modern structures of Paris. We see it in the Pantheon, the Bourse, and the Madeleine; and if columns alone be allowed to constitute architecture, the second of these buildings may rank much higher than criticism can possibly place it; since, with the exception of the columns, it is not even Roman or antique at all in character, but a formal affectation, wherein, instead of being skilfully blended together so as to produce consistency of style, very opposite elements and modes of architecture are allowed to show themselves.

To proceed to particular buildings, we begin with the cathedral of Notre Dame, the construction of which, says Woods in his 'Letters of an Architect,' 'may be considered as among the boldest and most successful existing in Gothic architecture.' To an English eye however it does not appear the most pleasing specimen of that style; the western front indeed is even disagreeably compact and heavy in its general *form*, probably in consequence of the design not having been completed, since we may presume it was originally intended to crown the two towers by spires. There are many other parts which have evidently *never* been finished, the consequence of which is, that there is a disagreeable contrast between the elaborate richness of some features in the building and the meagreness of the rest. For a detailed description of the whole edifice we must *refer* to that given by Mr. T. Moule, in Weale's 'Continental Cathedrals,' limiting ourselves here to a *few* particulars of its plan and dimensions. The extreme length externally is 430 feet; do. breadth 162; breadth of nave 40, length of do. to transept 156, transept 148, width of front 134, and height of towers 221 feet. The plan is divided into a nave and four aisles, besides a range of seven chapels on each side between the external buttresses; consequently the projection of the transept, or form of the cross, does not show itself at all in the lower part of the building. Still, notwithstanding its greater magnitude, the interior is *frequently* estimated by English travellers as being much less than that of Westminster Abbey, which is probably because they judge chiefly *from* the effect of the naves in the respective buildings.* In the richness of plan produced by the additional aisles and chapels connected with them, the interior of Notre Dame must be allowed to surpass the Abbey, but the latter is superior in point of style, while Henry VII.'s chapel has no parallel in the French capital. During the Revolution, Notre Dame suffered considerable injuries, which have since been repaired under the direction of M. Godde, the architect now employed on the Hôtel de Ville.

If our Westminster Abbey has a rival in Notre Dame, the same cannot be said of our St. Paul's, since Ste. Geneviève, or the Pantheon, falls very far short of the latter, although a work of great merit; of infinitely more, in fact, than a modern French writer (Victor Hugo) has allowed. Very different is the opinion of an able architectural writer (Woods), who says, 'It is certainly a beautiful edifice, the general proportions are good, and there is much grace and elegance in the outline, but there are also many defects.' Compared with the church of the Invalides the exterior presents a totally different style of design, and one marked by grandeur and simplicity. Instead of two small orders so disposed as to create confusion, a single large one, whose columns are sixty feet high, forms a Corinthian hexastyle crowned by a pediment filled with sculpture; there are however twelve other columns, besides four attached ones, for the arrangement of which, as it is not very easy to describe, we refer to PORTICO. The entablature is continued along the whole building, of which it constitutes almost the sole decoration, there being no windows, as the interior is lighted by the dome, and by large semicircular windows above the internal colonnades, which are not visible externally. Hence it has been objected that the sides of the edifice look too plain and bare in comparison with the portico and dome; yet although somewhat more of embellishment would be an improvement, the absence of windows and the extent of unbroken surface give by contrast additional value and relief to the two principal features. The lower part of the dome is encircled by a Corinthian peristyle of thirty-two columns 36 feet high, on an unbroken podium, or stylobate. The interior is a Greek cross in plan, the length from east to west being 295 feet, that of the transept 262, and the breadth uniform, namely, 104. Instead of pier-arches, the aisles are formed by insulated Corinthian columns 40 feet high, thereby producing an air of great richness and lightness. The dome having been described elsewhere, and a section of it given, we refer for an account of it to DOME, pages 68 and 79, where will also be found a notice of that of the Invalides. The total length of the Pantheon, including the portico, is 362 feet.

The new church of the Madeleine, if in some respects superior to the first-mentioned edifice, in others falls short of it, and having no dome, it does not, like that, form a conspicuous object from a distance. Externally, it is merely the model of a Corinthian peripteral temple, upon a noble scale, and so far a very fine piece of classical architecture, perhaps the most imposing in magnitude and the most chaste in character ever produced in modern times.† The dimensions are 328 feet by 138 (those of the Parthenon, only 228 by 100), independently of the projection of the flights of steps at each end, which make the total length of the base or substructure 418 feet; the stylobate, on which the columns are raised, is about 13 feet high; the height of the columns 62; that of the entablature nearly 14, and the entire height from the ground to the apex of the pediment 115 feet. There are in all fifty-two columns; therefore as the porticoes are octastyle, there are eight at each end, and twenty along each side, those at the angles being reckoned again. The door of the south or principal entrance is 32 feet high by 16 wide, and is of bronze, with ten pannels sculptured in relief by Triquetti, with subjects bearing allusion to the Ten Commandments. The interior measures 259 feet by 52, and consists of three compartments in length, covered by as many flat domes, through which the building is lighted, there being no side windows. The roof is entirely of iron and copper, and it is said that no timber has been used in the construction of any part of the building.

---

* In the English one the width of that part is 38 feet, and its length to the transept 200; whereas in the other they are 42 and 195; consequently in the first the proportional length is very much greater, besides which that effect is increased by a greater number of divisions or arches, namely, twelve in the nave of the Abbey, while there are only ten in that of Notre Dame. To facilitate comparison we here subjoin some other measurements of the Abbey: extreme length, including Henry VII.'s chapel, 530 feet; length of chapel 110, width of trans. 110, height of towers, including pinnacles, 225.

† The Town-hall at Birmingham may be quoted as an instance of an octastyle Corinthian peripteral, at least so far as regards the front and sides, for the columns are not continued at the other end; but it is by no means a happy application of such an arrangement, the effect of the colonnades being greatly impaired by the large and numerous windows within them. Besides this the order is raised not on a solid stylobate, but on a lofty basement, pierced with arched doors and windows.

The Louvre, which has long ceased to be a royal habitation, though one of the noblest palatial structures in Europe, is nearly a square, of 576 feet by 538, enclosing a court 394 feet square. The celebrated east front or colonnade is in a style of simple grandeur almost unprecedented, and is so far the very reverse of the Tuileries. The fault usually alleged against it is the coupling of the columns, which is undoubtedly contrary to the practice of the antients, and consequently open to the censure of those who are guided by rules. Yet the effect itself is by no means unpleasing, or rather a peculiar species of richness is thus produced. Unfortunately the basement is not only too high and too plain for the order, which is exceedingly rich, but the size of the windows detracts considerably from the effect of the columns, while their form, which is segmental-headed, produces an offensive discord as to style. Another striking defect is occasioned by the break in the lower part of the centre division, and the large arch being carried up above the level of the basement; which has in turn occasioned one of the greatest blemishes as regards the order itself, namely, the excessive width of the central intercolumn beneath the pediment, which is much more than double any of the others—so wide as to produce the appearance of weakness and poverty of columniation where they ought to have been especially avoided: so far the centre compartment of the south front, or that towards the Seine, is in infinitely better taste. The great gallery extends from the Louvre to the Tuileries, in a line of more than 1400 feet, but the architectural effect is by no means commensurate with the extent. The interior of the Louvre has undergone repeated changes and modifications, and among recent ones are the newly decorated rooms, eighteen in number, appropriated as a museum of Egyptian antiquities, also the new museum of Spanish painters, which contains 405 pictures in five rooms.

The Luxembourg Palace, now the Chamber of Peers, was erected by Mary de' Medici, and is a good specimen of its particular style (the Florentine), where three orders are introduced with rusticated columns and pilasters. It consists of a centre and two wings, which latter are connected by a screen of arcades, in continuation of the lower order, decorated in the centre with a lofty pavilion or vestibule, in three orders, and covered by a dome, and thus enclosing the court (about 196 feet by 230) from the street. One of the most splendid features of the interior is the grand staircase leading to the hall of the Peers, executed by Percier and Fontaine; the hall, or 'chambre,' itself is a semicircle about 80 feet in diameter, lighted from the roof, and decorated with Corinthian columns.

The Chamber of Deputies, formerly the Palais Bourbon, is remarkable for the modern façade towards the river and Place de la Concorde. The whole extent of this side of the building is 236 feet, 136 of which form an advancing central mass faced by a Corinthian portico of twelve columns, leading up to which is an ascent of steps, about 15 feet high, flanked by pedestals and statues. Notwithstanding that it is only a single intercolumn in depth, this portico makes an exceedingly majestic appearance, which is not only owing to its unusual extent, and the richness of its entablature and sculptured pediment, but to the absence of what generally mars all modern pseudo-Grecian designs. No part of the façade is cut up by apertures, but consists almost entirely of lightly rusticated surface, with no other decoration than pannels filled with sculpture; while the doors within the portico occupy only the alternate intercolumns. The 'chambre,' which is behind the portico, is similar in plan to that of the Peers, being a semicircle lighted from above, and surrounded by an Ionic colonnade.

The Hôtel des Monnaies, or Mint, by Antoine, on the Quai Conti, near the south end of the Pont Neuf, is a noble structure of palatial aspect, although certainly without anything characteristic of its particular purpose. It has two fronts of nearly the same extent, 376 feet, one towards the Quai, the other in the Rue Guénégaud. The former is in three divisions, the centre one of which has an Ionic order of six columns above the basement, crowned by an attic, against which are statues over the columns and pannels between them. There are two series of windows in the height of the order, and twenty-seven on a floor. The whole is marked by great nobleness and simplicity, and is comparatively pure in taste.

Although without much architectural beauty, the Halle aux Blés, or Corn-market, merits notice for its convenience and agreeable effect of plan. It is a rotunda whose external diameter is 225 feet, containing within a circular arcade of twenty-five arches, leaving a clear central space, 127 feet in diameter, which was originally an open court, but was afterwards covered in by a timber dome, pierced with *rayons*, or oblong lights, corresponding in number with the arches below. This dome having been destroyed by fire, the present dome was afterwards constructed of iron and copper, and different also in design, there being now only a single skylight in the centre, similar to the opening in the dome of the Pantheon at Rome.*

The Bourse is an insulated building standing in the centre of a large square or *place*. The form is a parallelogram, measuring 164 feet by 234, and is entirely surrounded by a Corinthian peristyle of sixty-four columns, of which there are fourteen at each end, besides which there are two others, viz. behind the second one from each angle of the west front, the portico being there two intercolumns in depth. The columns are 40 feet high and raised upon a solid stylobate of 10 feet, and the extreme height from the ground to the top of the attic, or podium above the entablature, is rather more than 68 feet. As far as mere effect of columniation goes, this structure may be called classical, but it is by no means entitled to the praise which has been indiscriminately lavished upon it. As far as regards the general form, it is that of a Greek temple stripped of its pediments; consequently not only is a very disagreeable monotony produced, but, except the ascent at the ends, there is no marked indication of front, each side being perfectly alike, and it further appears as if it had been intended that the building should be perfectly square. There is no occasion to object to the windows, &c. within the colonnades being arched, because the number alone of those openings destroys the repose so essential to architectural dignity. Like the portico of St. Martin's Church, London, when viewed by moonlight, so that the columns alone show themselves, and all that is behind them is veiled by obscurity, the Bourse is seen to greatest advantage. According to the first design, which had the same number of columns, the order was to have been Ionic; another difference is that, at the west end at least, there would have been no second range of windows, but a long pannel with sculpture and circular reliefs on each side of it, in lieu of such windows. The interior contains several offices and other apartments, and a large central hall for the Exchange—108 feet by 59 (exclusive of the arcades or galleries by which it is surrounded on both floors), and lighted by a central skylight in the vaulted roof.

Passing by several other buildings, some of which will be found mentioned in the annexed table, we must notice three structures of a monumental class, which eclipse everything of the kind in our own metropolis—the Colonne Vendôme, the Arc de l'Etoile, and the Colonne de Juillet. The first-mentioned of these falls far short of the monument of London in magnitude, its entire height being only 132 feet, while that of the other is 202. It is indeed only a few feet loftier than the York column, and, in its general design, merely a copy of that of Trajan; but then it is a copy worthy of the original, the shaft being entirely covered with bronze reliefs, the work of thirty different artists, who executed them under the direction of Denon. The pedestal is likewise highly enriched, and it is this assemblage of sculpture which constitutes the merit and effect of the whole as a work of art, the reliefs, &c. being not so much accessory decorations to the column, as the column is the form adopted for displaying the historical sculpture. The following are the respective diameters of the Monument, York Column, and Colonne Vendôme—15 feet, 11ft. 7½in., and 12ft. 10in. In 1814 the bronze statue of Napoleon, in Roman costume, modelled by Chaudet and cast by Mesnel, was taken down, and afterwards recast to form the horse of the equestrian statue of Henri IV.; but a second bronze figure of Napoleon, in a military dress, designed by the sculptor Seurre, was put up July 28, 1833: it is 13 feet high, or about a foot and a half more than the first.

---

* This spacious covered area, surrounded by a wide portico of arcades, seems to offer an excellent model for an Exchange, it being every way preferable to an open court with merely sheltered walks around it, and capable of accommodating a greater number of persons, in proportion to its area.

The Arc de l'Etoile is, without exception, the most gigantic work of its kind either in ancient or modern times; nor can we perhaps give a better general idea of its colossal dimensions than by stating that eight such structures as Temple Bar, London, would stand within the great arch, that is, four in depth and as many above them, the arch of the Etoile being 47ft. 10in. wide, 95ft. 6in. high, and 73ft. in depth. This structure is perfectly insulated, and forms a mass whose plan is 147 feet by 73, and its height 162, the effect of which extraordinary dimensions is greatly enhanced by its simplicity of form and its solidity, the outline being unbroken by columns and projecting entablatures, and there being only a single opening on each side, viz. the large arch in the direction of east and west, and the smaller one running transversely through the plan from north to south: the height of the latter is 64 feet, and the breadth 27½. There are no columns or pilasters, and the architectural forms are exceedingly simple, but at the same time prodigiously rich: the entablature is 23 feet deep, and the frieze is entirely covered with figures in relief, besides which the mouldings of the cornice are carved, as are likewise those of the archivolts and imposts of the arch. An unusual degree of decoration is also bestowed upon parts where it is often omitted altogether, namely, in the passages through the structure, where the soffits of the archivolts and the vault are richly pannelled and coffered, and the piers formed by the intersection of the smaller arch are covered with wreaths and inscriptions. If it were remarkable for nothing else, this monument would be eminently so on account of the display of sculpture, there being four colossal groups of sculpture, one on each side of the arch in the east and west fronts, the height of which, including their pedestals, is upwards of 36 feet, and that of the figures themselves about 20. Corresponding with these, and above the cornice forming the impost to the large arch, are as many large bas-reliefs. The attic also has a great deal of sculptured ornament. Within the upper part and attic there is, besides some other rooms, a spacious hall, extending from end to end of the building.

The Colonne de Juillet, erected on the Place de la Bastille, in commemoration of the second Revolution, is somewhat loftier than that of the Place Vendôme, but similar in character, yet different in construction, the bronze exterior of the shaft consisting of twenty cylindrical bands or rings, not attached by cramps, but fitted into each other by grooves. The capital is to be cast in one mass, and it is proposed to surmount the whole by a bronze statue. Since Alavoine's death, the execution has been entrusted to Lenoir and Duc.

Under OBELISK there is an account of the Luxor obelisk, now erected in the centre of the Place de la Concorde. Among other embellishments and architectural works, either recently completed or now in progress, may be mentioned the Ecole des Beaux Arts, on the quay between the Pont du Carrousel and the Pont des Arts, an edifice which partakes of the Renaissance style, and in front of which have been erected the portal of the Château d'Anet and that of Château Gaillon. There are also several other buildings, of which it would be premature to attempt to speak at present; for instance, the extensive alterations of the Hôtel de Ville, Palais de Justice, the Gothic church by Gau, in the Faubourg St. Germain, &c., as some time must elapse before they are completed. In fact every year makes some addition to the architecture of Paris.

Table of Public Buildings.

	Date.	Architect.	Remarks.
St. Germain des Prés	ded. 1163		A striking specimen of French architecture of its period. The chapel of the Virgin by Pierre de Montereau. Length 310 feet.
Notre Dame	1010-1260		Total length 442 feet.
La Sainte Chapelle	1242-8	Pierre de Montereau	A beautiful Gothic edifice, divided internally into two stories.
St. Germain l'Auxerrois			Gothic. Length 250 feet. Interior, five aisles and side chapels.
St. Severin	fin. 1495		A fine Gothic specimen.
Hôtel de Cluny	1490-1505		Now converted into a museum.
St. Mary	1520		Gothic.
St. Eustache	1532-42		Interior Gothic.
——— façade	1754	Mansard de Jouy	Two loggie, Doric and Ionic, and two towers, Corinthian.
Fontaine des Innocens	1551	Lescot and Goujon	Now insulated, and forming an upright square pavilion, covered by a dome, and having a large open arch on each side. Remarkable for the beauty of the sculptures.
Hôtel de Ville	1533-1606		Front a singular and uncouth architectural mixture.
Old Louvre	1530-48	Lescot	Profusely adorned with sculpture.
St. Etienne du Mont	1517		Interior Gothic.
——— façade	1610		A barbarous medley, though rich in parts.
Tuileries	1564	Delorme & Bullant	Not only vicious, but positively ugly as to style, nevertheless grand and imposing; garden façade nearly 1100 feet.
Pont Neuf	1578-1610	Du Cerceau	Length 926 feet. Twelve semicircular arches. In better style than any of the later bridges.
St. Gervais	1581		
——— façade	1616	J. Debrosses	A lofty mass, about 140 feet high, Doric and Ionic, with a third order, Corinthian, over centre.
Palais de Justice			
Palais du Luxembourg (Chambre des Pairs)	1614	J. Debrosses	Three orders rusticated; coupled columns; stately in character. Interior greatly altered by Chalgrin, &c. The Chamber of Peers, a semicircle 80 feet in diameter.
Val de Grace	1645	Fr. Mansard	A preposterous composition; façade in two orders, with pediments to both. Dome of enormously lofty proportions, the height being 177 feet, and diameter only 66.
Église de Sorbonne	1650-3	Le Mercier	Hexastyle Corinthian portico; octagonal dome.
Collége Mazarin (Institute)	1663	Levau	Corinthian portico; four columns, those at the angles coupled with a pilaster. Dome with coupled pilasters and arched windows between them.
Observatory	1667-72	Perrault	
Louvre, East front	fin. 1670	Perrault	Length 576 feet; façade in five divisions, centre and two pavilions connected by Corinthian colonnades of coupled columns, forming seven intercolumns each.
Assumption, Church	1670-6	Errard	A rotunda of singular proportions, diameter 78 feet, height to top of dome 144 feet. Low façade, with hexastyle Corinthian portico.
Porte St. Denis	1672	Blondel	A structure marked by simplicity and grandeur. Width 82 feet, depth 22 feet, height 85 feet.

	Date.	Architect.	Remarks.
Porte St. Martin	1674	Bullet	A simple and well proportioned mass, crowned by a handsome entablature, and an attic. Width 56 feet, height 60
Hôtel des Invalides	1675	Lib. Bruant	Style exceedingly heavy and bad. Façade 650 feet. Court 360 feet by 230.
—— Dome	1706	J. H. Mansard	Total height 292 feet, dome gilded.
Place des Victoires	1685	J. H. Mansard	Nearly a circle, 260 feet diameter.
Place Vendôme	1699	J. H. Mansard	Uniform elevations, a Corinthian order on arcades. A square of 430 feet, with angles cut off.
		Eighteenth Century.	
Palais de l'Elysée	1718	Mollet	
Palais Bourbon (Chamber of Deputies)	1722	Girardini	An extensive pile greatly altered and extended at different times. Hall of Louis Philippe added by Joley about 1836
St. Sulpice, façade	1733	Servandoni	Two orders, Doric forming a loggia, Ionic on lofty pedestal with arcades between the columns. Two towers.
St. Roche, façade	1736	De Cotte	Two orders, Doric and Corinthian.
Fontaine de Grenelle	1739	Bouchardon	A showy architectural façade.
Ecole Militaire	1752	Gabriel, J. A.	Façade towards the Champ de Mars, 340 feet, centre a Corinthian tetrastyle.
Garde-meubles	1760	Gabriel, J. A.	Two duplicate façades towards the Place de la Concorde.
Halle aux Blés	1762	Camus de Mezieres	A low rotunda 228 feet diameter. What was originally an inner circular court, 127 feet diameter, was covered by a timber dome, by Legrand and Molinos, 1782, which, being burnt, was replaced by the present metal one, 1806, by Bellanger.
Ste. Géneviève (Pantheon)	1764	Soufflot	Portico 18 Corinthian columns (62 feet high), disposed in front as an hexastyle.
École de Chirurgie	1769	Gondouin	Greatly praised, but in many respects very poor. Almost the only good feature is the Corinthian hexastyle portico within the court.
St. Philippe du Roule	1769-84	Chalgrin	By far the most tasteful specimen of church architecture of its period.
Mint	1771	Antoine	Remarkable for its simple grandeur of character.
Palais de Justice	1777	Moreau, &c.	The new front and court.
La Madeleine	1777	Contant d'Ivry	The building first begun at this period, but quite altered by succeeding architects.
Hôtel Thelusson	1780	Ledoux	Remarkable for the rusticated mass (forming the entrance) pierced by a single low arch 30 feet wide.
Palais Royal, street façade	1781	Moreau	Insignificant in style. The ranges of buildings and arcades towards the garden were erected about the same time.
Lycée Bourbon	1781	Brogniart	A façade of unusual simplicity and elegance with three large doors, niches and bas-reliefs; no windows.
Théâtre de l'Odéon	1782	Dewailly and Peyre	The façade has more of a disagreeable affectation of severity than of either beauty or propriety.
Théâtre Italien (Favart)	1783	Heurtier	At one time greatly admired for its portico or hexastyle Ionic colonnade, though poor in style and without merit as a composition. This structure was burnt down in 1836.
Hôtel de Salm (Palais de la Legion d'Honneur)	1786	Rousseau	Its chief architectural merit, the gateway and Ionic screen of two rows of columns on each side of it.
Pont Louis Seize	1787-90	Perronet	A stone structure of five flat arches; length 1065 feet.
Opera House (Académie de Musique)	1791		Front two orders, Doric and Ionic, with 9 arcades in each.
		Nineteenth Century.	
Rue Rivoli	1802	Percier	
La Madeleine	1804-36	Vignon, Huvé, &c.	A Corinthian peristyle of 52 columns (8 at each end) 62 feet high, raised on a stylobate 13 feet high.
Pont des Arts	1804	Cessart & Dillon	For foot-passengers only: arches cast iron, piers stone.
Arch of the Tuileries	1805-10	Percier & Fontaine	Each front has four Corinthian columns (shafts red marble, and bronze capitals), with a central arch and two smaller ones.
Vendôme Column	1806	Gondouin & Lepère	Stone cased with bronze reliefs; total height 141 feet.
Arc de l'Etoile	1806-36	Chalgrin, &c., finished by Debret	Width 147 feet, height 162 feet, depth 73 feet. Arch 47 feet wide, 96 feet high.
Pont des Invalides (Pont de Jena)	1806	Lamandé	Five arches, length 518 feet.
Fontaine du Palmier	1806-8	Bralle	A column on a pedestal, surmounted by a figure of Fame on a globe. Height to top of capital 49ft. 3in.; total height, with statue, 56 feet.
Portico, Chamber of Deputies	1807	Poyet	A single range of twelve columns (44 feet high) beneath a pediment.
Bourse	1808-1824	Brogniart and Labarre	A Corinthian peristyle of 64 columns (40 feet high), 14 at each end.
Hôtel des Affaires Etrangères (Quai d'Orsay)	1810-1837	Bonnard and Lecointe	An extensive pile, of which the projecting portion forming the façade towards the quay is 370 feet, and consists of two orders, Doric and Ionic, surmounted by an attic, and each containing 19 large arcades or windows.

	Date	Architect	Remarks
Halle aux Vins	1811-13	Gaucher	
Bondy Fountain	1811	Girard	A large circular basin 90 feet in diameter, with other basins or terraces rising from it.
Marché St. Germain	1813	Blondel, M. J. B.	
Chapelle Expiatoire	1815-26	Percier & Fontaine	Tetrastyle portico, Roman Doric attached to a square mass, whose three other sides have semicircular projections crowned by semidomes against the attic of the square part.
École des Beaux Arts	1824-37	Duban and Labrouste	Two Corinthian orders (one in columns, the other in pilasters), upon a basement. The gateway or screen from Château Gaillon, erected in front of the building.
July Column	1833	Alavoine	Pedestal stone, column bronze, total height 154 feet; 13 feet higher than the Vendôme Column.
Pont du Carrousel	1834-6	Polonceau	Timber and iron, with stone piers and abutments. Three arches, centre one 157 feet span, and 16½ rise. Total length 338 feet.
Palais de Justice	1834		Interior remodelled and rebuilt chiefly in the Renaissance style.
Hôtel de Ville	1835	Godde and Lesueur	Restorations, &c. Renaissance style.
Luxor Obelisk	1836		Raised by Lebas, October 25.
Place de la Concorde		Hittorff	Embellished with fountains and architectural decorations.
Notre Dame de Lorette	1823-36	Lebas	Portico, tetrastyle Corinthian.
St. Vincent de Paul		Hittorff and Lepère	
[illegible] Bonne Nouvelle	1837	Froehlicher and Grisart	
Church, Faubourg St. Germain	1839	Gau	Gothic.

The population of Paris at the end of the reign of Louis XVI. (1791) has been estimated, by a calculation founded on the number of births, at upwards of 610,000. The troubles of the Revolution, and the emigrations consequent thereon, must have materially diminished the number; but on the comparative quiet which followed the overthrow of Robespierre, it is probable that the diminution was checked. The calculations formed in the years 1798-1800 exceed that of 1791; but these calculations can only be regarded as loose approximations, for upon the institution of a regular census in 1806-1808, the population, exclusive of the military, was shown to be only 580,609. The next census appears to have been in 1817, when a deficient harvest had led many destitute persons to resort to Paris. There were then ascertained to be *26,751* houses, and 224,922 families, comprehending 657,172 individuals. The hospitals, military establishments, prisons, hotels, and other places for individuals not domiciliated, contained 57,424 persons; making a total of 714,596, of whom no less than 100,000 (in round numbers) were prisoners, inmates of hospitals, or persons receiving charitable relief. (Dulaure, *Hist. de Paris.*) In 1826 the population was 890,431; in 1831, 774,338; and in 1836, 909,125. The extraordinary diminution in the return for 1831, as compared with the preceding return for 1826 and the succeeding return of 1836, was probably owing to some unnoticed variation in the districts included in the return. A remarkable feature in the return for 1817, and which may be considered as applying to the subsequent returns, is the number of families as compared with that of houses. The inequality is accounted for by the vast height of the houses, which are sometimes of eight stories in the older parts of the town, and by the practice of different families occupying suites of apartments in the same house, a practice not confined, as in London, to the humble classes, but common, as in Edinburgh, to all ranks.

The students of various classes form a considerable part of the population of Paris; and in the political excitement which preceded and followed the Revolution of 1830, they acted a very conspicuous part. In 1828 the Académie Universitaire, or University of Paris, was attended by from 7000 to 8000 students; it is the most frequented university in the world. The other institutions for superior education were also attended by a great number of students, swelling the total number to nearly 15,000. There is also a considerable manufacturing population; for in the variety and extent of its productions of industry, Paris may vie with most cities of the world. The carpets of the manufactory of La Savonnerie and the tapestry of the Gobelins are well known. The two establishments are now united at the Gobelins. Cashmere, silk, and woollen shawls; light woollens, cotton goods, hosiery, gloves, hats, embroidery, lace, and other articles of fashionable attire; jewellery, gold and silver plate and trinkets, clocks and watches, bronzes, and musical, mathematical, and philosophical instruments; paper-hangings, household furniture, carriages, saddlery, leather, glue, cutlery, fire-arms, liqueurs, and confectionary are made. Dyeing, printing, engraving, and lithography; the manufacture of salts, acids, oxides, and other chemicals; the refining of sugar, tallow-melting, the distillation of brandy from potatoes, brewing, and the manufacture of potato-starch, are carried on with considerable activity. The number of periodicals published is estimated at 300. The trade of the place comprehends the above-mentioned articles and others requisite for the supply both of the town itself and the district of which it is the emporium. The great manufactures of Lyon, Rouen, and the other chief manufacturing towns of the provinces, have their agencies and their dépôts at Paris. The Seine furnishes the principal means of water-carriage: it is navigable for barges and other small craft. The canal of the Ourcq, which opens a communication with the country to the north-eastward, terminates in the basin of La Villette, just outside the wall of Paris, on the north-east side of the city; and the canals of St. Martin and St. Denis open a communication between the canal of the Ourcq and the Seine. The canal of St. Martin enters the Seine in the very heart of Paris, opposite the island Louvier: its termination toward the Seine is formed by the *gare* (basin or dock) of the Arsenal. The canal of St. Denis opens into the Seine at the town of St. Denis, a short distance north of Paris in the direct line, but a much greater distance following the winding of the river.

In 1824 and 1825 about 15,000 or 16,000 barges and other craft arrived at Paris, besides trains of fire-wood or timber floated down the main stream, or its affluents the Marne and the Oise. Wood is the principal fuel consumed at present, but the consumption of coal is gaining ground. The principal articles conveyed by the river in boats are wine and brandy; grain, pulse, and flour; butter, fish, and fruit; groceries, spices, salt, and oil; hay and straw; bricks, tiles, and stone; cotton, linens, and other woven goods; iron and other metals; earthenware and glass; soap, tobacco and snuff, soda, drugs, paper, &c. For the supply of provisions there are numerous markets, covered or open. The corn-market (*Halle aux Blés*) is in the neighbourhood of the Louvre. The principal granary, known as the *Grenier de Réserve*, extends along the side of the gare (or basin) of the Arsenal, which opens into the Seine: it is an immense building, commenced by Napoléon, but never finished to the extent at first proposed. It is above 1100 feet in length.

and about 75 feet high. The basement is a storehouse for wine and oil. Napoléon designed to erect a large covered meat-market (*Halle à la Viande*) near the *Halle aux Blés*. The space cleared for the purpose (about 360 feet by 175 feet) has been fitted up with wooden stalls, and is appropriated as a market-place for meat: it is supplied with water by six fountains fixed against the wall (*bornes-fontaines*). The poultry-market (*Marché à la Volaille*) is on the south bank of the Seine, opposite La Cité. It is a covered market, about 200 feet long and 150 wide, divided into three parts by rows of pillars and iron rails. The fish-market, near the *Halle à la Viande*, or meat-market, is a covered building, supported by a great number of columns. The *Marché des Innocens*, for fruit, vegetables, and flowers, is an open square in the same neighbourhood, surrounded by small shops for the market-people, and adorned in the centre by a handsome fountain. The *Marché St. Germain*, not far from the Luxembourg Palace, is the largest and best constructed market in Paris: it is an open square of about 300 feet long by 240 or 250 feet wide, with a covered arcade or piazza all round, and having a fountain in the centre. There are vast cellars. The *Halle aux Vins*, or wine depôt, on the south bank of the Seine, opposite the islands St. Louis and Louvier, is a vast enclosure, comprehending extensive covered storehouses for wines and ranges of cellars. Besides the above there are several other markets, and some halls designed for the sale of other articles than provisions, as the wool depôt, the cloth-hall, the leather-hall or skin-market, &c. There are five abattoirs, or general slaughter-houses, in the outskirts of the city, three on the north side of the Seine, and two on the south side, commenced by Napoléon, and finished under the Bourbons: they are of great extent, and under excellent regulation.

A considerable part of the southern quarters of Paris (including the Luxembourg Palace, the churches of Ste. Géneviève and St. Sulpice, and the Observatory) stands on excavations from which the stone was procured for the building of the city. A part of these excavations is occupied by the catacombs, or depositories of the bones brought from the disused cemeteries in the heart of Paris. Nearly all the present burial-places are without the enclosure of the city walls; that of Mont Louis, better known as the cemetery of Père La Chaise, on the north-east side of the city, is the principal.

The offices of the general government and the buildings connected with it are numerous. Paris is the residence of the king, who has the palaces of the Tuileries, the Louvre, and the Palais Royal; and the seat of the legislature, of which the Chamber of Peers meets in the Luxembourg palace, and the Chamber of Deputies in a building annexed to the Bourbon palace. The hôtels, or the offices of the executive government, are chiefly in the neighbourhood of the Tuileries; the chief courts of law are held in the Palais de Justice, in the island of La Cité. The Cour de Cassation is the supreme law court of the kingdom. The Cour Royale of Paris has jurisdiction over the departments of Seine, Seine et Oise, Seine et Marne, Aube, Eure et Loir, Marne, and Yonne. The head-quarters of the first military division, which includes the departments of Seine, Seine et Oise, Seine et Marne, Aisne, Oise, Loiret, and Eure et Loir, are also at Paris.

For the purposes of municipal government, Paris is divided into twelve parts, called 'arrondissemens,' which are subdivided each into four 'quartiers' (quarters), as follows:—

Arrondissemens.	Quartiers.
I.	Du Roule, des Tuileries, des Champs-Elysées, de la Place Vendôme.
II.	De la Chaussée d'Antin, de Feydeau, du Palais Royal, du Faubourg Montmartre.
III.	Du Faubourg Poissonnière, de Montmartre, de St. Eustache, du Mail.
IV.	De St. Honoré, des Marchés, du Louvre, de la Banque de France.
V.	De Bonnes Nouvelles, du Faubourg St. Denis, du Faubourg St. Martin, de Montorgueil.
VI.	Du Temple, des Lombards, de la Porte St. Denis, de St. Martin-des-Champs.
VII.	Des Arcis, de Sainte Avoye, du Mont-de-Piété, du Marché St. Jean.
VIII.	Des Quinze-vingts, de Popincourt, du Faubourg St. Antoine, du Marais.
IX.	De la Cité, de l'Arsenal, de l'Ile St. Louis, de l'Hôtel de Ville.
X.	Des Invalides, de la Monnaie, de St. Thomas d'Aquin, du Faubourg St. Germain.
XI.	Du Luxembourg, du Palais de Justice, de l'École de Médicine, de la Sorbonne.
XII.	De l'Observatoire, de St. Jacques, du Jardin des Plantes, de St. Marcel.

Each arrondissement has a separate mairie, or municipality, over which a maire (mayor) presides. There is also a justice of the peace to each of the twelve arrondissements, who sits at the public office of the arrondissement; and a commissary of police to each of the forty-eight quarters. The council of the department over which the prefect presides [DEPARTMENT] forms a municipal council for Paris. The municipal police has charge of the safety of the public, and the sanatory regulations of the city are confided to it. It is under the direction of a prefect of police, whose office is in the island of La Cité. The police force consists of the town-serjeants and a municipal guard of horse and foot. The national guard of Paris amounts to 80,000 men, with 24 cannon. The regulations for protection against fire and for the extinguishing of fires are excellent. There is an organised body of firemen (*sapeurs-pompiers*), who are distributed in their barracks or stations. There are two large forcing-pumps called *pompes à feu* (fire-pumps), with immense reservoirs, in the western part of the city, on the opposite banks of the Seine. They supply water to many of the fountains, and are worked by steam. The supply of water is generally by public fountains, and not commonly, as with us, by pipes furnishing a supply to every house.

Before the Revolution of 1789, Paris possessed one hundred and sixty places of public worship of the Catholic church, viz. fifty parish churches, ten others with the same rights as parish churches, twenty collegiate churches, and eighty chapels-of-ease; besides three abbeys, and fifty-three other monastic establishments for men, and eight abbeys and forty-six other establishments for women. According to the last edition of Malte Brun (Paris, 1832), there were forty-one Catholic places of worship, namely two basilicæ, or principal churches, twelve churches, and twenty-seven chapels-of-ease. There were very few ecclesiastical communities for men (only four), but several for women; four or five seminaries for the priesthood, two Reformed churches and one Lutheran church, one Greek church, and one Jewish synagogue. Some other places of worship have since been added.

We have no data respecting the institutions for primary or elementary instruction applicable to the present time. Of colleges or public schools of a higher grade there are seven, namely, those of Louis le Grand, of Henri IV., of St. Louis, of Bourbon, of Charlemagne, of Ste. Barbe, and of Stanislas. Of educational establishments of the highest class, or for special or professional instruction, the most important is the Académie Universitaire, or university, with from 7000 to 8000 students. The Collège Royal de France, which may be regarded as equivalent to a university though without the name, has nearly 1000 students; and the lectures on natural philosophy at the Jardin des Plantes are attended by 3000 persons. The Royal Conservatory of Arts and Trades is attended by about 1000 pupils. To these may be added the Polytechnic School, the schools of medicine, of astronomy (at the Observatory), of engineering, of mining, of music and lyric and dramatic elocution, of the fine arts; and a number of others, especially the normal school for the instruction of teachers. The Museum of Natural History, and the Menagerie and Botanic Garden (usually known as the Jardin des Plantes) connected with it, are rich and valuable collections.

There are seventeen important libraries, six of them public, namely, the King's Library, with above 500,000 volumes, 80,000 MSS., 1,600,000 engravings, and 100,000 medals and coins; the Library of the Arsenal, with 180,000 volumes and 5000 MSS.; the Library of Ste. Géneviève, with 112,[illegible] volumes and 2000 MSS.; the Mazarin Library (at the Palais des Beaux Arts); the City Library; and that of the Museum of Natural History at the Jardin des Plantes. Of the libraries not open to the public, the principal is that of the Institute, with 70,000 volumes. The Palace of the Louvre is devoted to collections of paintings, statues, and other objects connected with the fine arts.

There are numerous learned societies, at the head of which is the Institute (*Institut National*), which for a long time comprehended four departments (or, as they are termed, *académies*), the *Académie Française*, the *Académie des Sciences*, *des Inscriptions et Belles-Lettres*, and *des Beaux Arts*. A fifth *Académie*, that of the moral and political sciences, has been added by Louis Philippe, the present king. [INSTITUT NATIONAL.]

The charitable institutions are numerous. There are seventeen hospitals, five of them for the military. The most important of the non-military hospitals is the Hôtel Dieu, in the island of La Cité; of the military hospitals, the Hôtel des Invalides. There are also thirteen hospices, or asylums. Each arrondissement has its *Bureau de Charité*, for relieving the destitute at their own habitations; these bureaux distribute annually about 1,000,000 francs, or 40,000*l*., and relieve from 60,000 to 70,000 persons. There are a variety of other institutions for affording relief or giving employment to the destitute, and vast sums are distributed every year through the medium of the clergy. Nearly two hundred benefit societies exist among the working classes.

Paris contains numerous places of amusement. There are several theatres within the circuit of the town wall, and others beyond the barriers: the most remarkable for their architectural beauty are L'Opéra Comique, Le Grand Opéra, L'Odéon, and Le Théâtre Favart. Public balls are common, and are frequented both in summer and winter; and the public gardens, especially the gardens of the Tuileries and of the Palais Royal, and the Boulevards are much frequented. Gaming houses were numerous and much frequented: it has been estimated that 11,000,000 francs, or about 440,000*l*., were annually risked in these places. The establishments were licensed by the government, and paid a heavy annual sum for their exclusive privilege. But since the beginning of 1838 the system of licensing has been discontinued. [GAMING.] Carriages of every kind, public and private, are numerous at Paris. Nearly one-third of the children born in Paris are illegitimate. The number of persons imprisoned in the department of Seine may on a yearly average be estimated at 20,500.

(Dulaure, *Histoire Physique, Civile, et Morale de Paris*, 10 tom. 8vo., Paris, 1829; Malte Brun, *Précis de Géographie Universelle*, 3rd ed., Paris, 1832, *seq.*; Balbi, *Abrégé de Géographie*, Paris, 1833; *Dictionnaire Géographique Universel*, Paris, 1831; 'Paris and its Historical Scenes,' in the *Library of Entertaining Knowledge*.)

PARIS, BASIN OF. [SEINE, Department.]

PARIS, ABBÉ. [JANSENISTS.]

PARIS, MATTHEW, was born about the end of the twelfth century, took the religious habit in the Benedictine monastery of St. Alban's in 1217, and died there in 1259. Almost the only incident of his life that has been recorded is a journey he made to Norway, by command of the pope, to introduce some reforms into the monastic establishments of that country, which mission he has the credit of having executed with great ability and success. He is said to have stood high in the favour of Henry III., and to have obtained various privileges for the university of Oxford through his influence with that king. His acquirements embraced all the learning and science of his age; besides theology and history, oratory, poetry, painting, architecture, and a practical knowledge of mechanics are reckoned among his accomplishments by his biographers or panegyrists. His memory is now preserved by his history of England, entitled 'Historia Major,' which begins with the Norman Conquest, and comes down to the year of the author's death. Of this work the following are the printed editions: 1. Fol., Lon., 1571, edited by Archbishop Parker; 2. Fol., Tiguri (Zürich), 1606, a mere reprint of the preceding; 3. Fol., Lon., 1640 (or, in some copies, 1641), edited by Dr. William Watts; 4. Fol., Paris, 1644; and 5. Fol., Lon., 1684. Watts's edition, which is sometimes divided into two volumes, besides various readings and copious indexes, contains two other works of the author never before printed, namely, his 'Duorum Offarum Merciorum Regum (S. Albani Fundatorum) Vitae,' and his 'Viginti Trium Abbatum S. Albani Vitae,' together with what he calls his 'Additamenta' to those treatises; and these minor productions are also given in the subsequent Paris and London editions. In the library of Corpus Christi College, Cambridge, there is an epitome, by Matthew Paris himself, of his History, generally referred to by the name of the 'Historia Minor,' or the 'Chronica,' which has never been published, but which, Bishop Nicolson says, contains 'several particulars of note omitted in the larger History;' and some other works, which are now lost, are attributed to him on the doubtful authority of Bale and Pits. Some old notices of his History speak of it as beginning at the creation of the world; and on this account it has been conjectured, though with no probability, that the historical compilation ascribed to the fictitious personage Matthew of Westminster, may really have been the composition of Matthew Paris. But even of the History which bears his name, the portion extending to the year 1235 is very little more than a transcript from the work of Roger de Wendover, Windleshore, or Windsor, who is said to have also been a monk of the monastery of St. Alban's. Mathew Paris writes with considerable spirit and rhetorical display; and his work, which is continued to the death of Henry III. (A.D. 1272) by William Rishanger, another monk of the same abbey, has been the *chief* authority commonly relied upon for the history of that reign. Its spirit however is somewhat fiercely and narrowly English; and from the freedom with which he inveighs against what he regards as the usurpations of the papal see, Romanist writers have always expressed strong dissatisfaction especially with his accounts of ecclesiastical affairs. Cardinal Baronius, while admitting his merits in other respects, characterises him as animated by a most determined hostility to the apostolic see ('animo infensissimo in apostolicam sedem'). Dr. Lingard goes much farther: 'It may appear invidious,' he says, 'to speak harshly of this favourite historian; but this I may say, that when I could confront his pages with authentic records or contemporary writers, I have in most instances found the discrepancy between them so great as to give to his narrative the appearance of a romance rather than a history.' It is admitted however in the sentence which immediately precedes, that this history or romance 'contains many original and some valuable documents;' 'but the writer,' it is added, 'accustomed to lash the great, whether clergy or laity, seems to have collected and preserved every malicious and scandalous anecdote that could gratify his censorious disposition.' With Protestant critics, on the other hand, Matthew Paris has been a favourite, in proportion to the dislike he has incurred from their opponents. Nicolson says, 'The whole book manifests a great deal of candour and exactness in its author, who furnishes us with so particular a relation of the brave repulses given by many of our princes to the usurping power of the Roman see, that it is a wonder how such an heretical history came to survive thus long.' At one time, it seems, it used to be affirmed by the Roman Catholics that the printed Matthew Paris was in many things a mere modern fabrication of the Reformers; but Watts, by collating all the manuscript copies he could find, and noting the various readings, proved that there was no foundation for this charge.

PARIS, also called **ALEXANDER,** one of the most celebrated characters of the mythic age, is said to have been the son of Priam and Hecuba. In consequence of an alarming dream which his mother had previous to his birth, Priam gave him to a slave to be exposed upon Mount Ida. The order was obeyed, but upon returning at the end of five days to the spot where he had exposed the infant, he found that he had been nursed by a bear. The slave took the child to his own home and brought him up as one of his sons, among the shepherds of Mount Ida. When Paris grew up, he became distinguished by his beauty and strength, and in consequence of his success in repelling the attacks of wild beasts and robbers, he is said to have obtained the name of Alexander (from ἀλέξειν). He was afterwards recognised by his parents, and received at the court of his father; but before he left his flocks he is said to have given that celebrated decision in favour of the superior beauty of Aphrodite (Venus), in consequence of which he obtained Helena, but at the same time brought upon himself and the whole Trojan race the implacable enmity of Here (Juno) and Athena (Minerva).

He is said to have carried off Helena from the court of Menelaus, while the latter was absent at Crete; and after touching at Sidon in his way home, to have brought her in safety to Troy. Herodotus however informs us (ii. 112-116), on the authority of the Egyptian priests, that Paris in his voyage home was driven to Egypt by unfavourable winds, and that Helen and all her property were detained by Proteus with the view of restoring them to Menelaus. Herodotus thinks that Homer was acquainted with this story, and quotes some passages in the Iliad and Odyssey in confirmation of his opinion.

We read very little in the Iliad of the exploits of Paris. In the third book he engages in single combat with Menelaus, and is only saved from death by the intervention of Aphrodite. He wounds with his arrows Diomed (xi. 369-383) and Machaon (xi. 505); and is mentioned in the twelfth book (l. 93) as a commander of one of the divisions of the Trojan army. According to later poets, he killed Achilles with one of his arrows. The manner of his death is variously told; but it is generally agreed that he was killed by Philoctetes with one of the arrows of Hercules. Later writers state that while he fed his flocks upon Mount Ida, he was married to Œnone, daughter of the river Cebren, who endeavoured to dissuade him from attempting to carry off Helen, but, unable to succeed in his endeavours, she told him to return to her if he was ever wounded, as she alone could save him. After being wounded by Philoctetes, Paris accordingly desired to be carried to Œnone; but offended by his desertion, she refused to heal him, and left him to his fate.

PARISH. This word is probably derived into the English language from the French *paroisse*, and the Latin *parochia* or *paroecia*, and ultimately from the Greek *paroikia* (παροικία). At the present day it denotes a circumscribed territory, varying in extent and population, but annexed to a single church, whose incumbent or minister is entitled by law to the tithes and spiritual offerings within the territory. In the early ages of Christianity the term appears to have been used in some parts of Europe to signify the district or diocese of a bishop, as distinguished from the 'provincia' of the archbishop or metropolitan. (Du Cange, *Gloss.*, ad verb. 'Parochia;' Selden's *History of Tithes*, chap. vi., sect. 3.) These large ecclesiastical provinces were gradually broken down into subdivisions, for which ministers were appointed, either permanently or occasionally, who were under the rule of the bishop, were paid out of the common treasury of the bishopric, and had no particular interest in the oblations or profits of the church to which their ministry applied. This was the state of things in the primitive times, which probably continued till towards the end of the third century. After that period proprietors of lands began, with the licence of the higher ecclesiastical authorities, to build and endow churches in their own possessions; and in such cases the chaplain or priest was not paid by the bishop, but was permitted to receive for his maintenance and to the particular use of his own church the profits or the proportion of the profits of the lands with which the founder had endowed it, as well as the offerings of such as repaired thither for divine service. This appears to be a probable account of the origin and gradual formation of parochial divisions in almost all countries where Christianity prevailed; and Selden has satisfactorily shown that the history of parishes in England has followed the same course. Soon after the first introduction of Christianity into this country, the heathen temples and other buildings were converted into churches or places of assembly, to which the inhabitants of the surrounding district came to receive religious instruction from the minister, and to exercise the rites of Christian worship. As the members of the new religion increased, a single or occasional minister was insufficient for the purpose; and a bishop, with subordinate priests, began to reside in the immediate neighbourhood of the religious houses, having the charge of districts of various extent, comprehending several towns and villages, and assigned principally with a view to the convenience of the inhabitants in assembling together at the church. Within these districts, or *circuits*, as they were called, which were precisely analogous to the diocesan *parishes* in other parts of Europe, the ministering priests itinerated for the purpose of exercising their *shriving*, but they always resided with the bishop. By degrees other churches were built to meet the demands for public worship, but still at first wholly depending upon the mother-church, and supplied by the bishop from his family of clergy resident at the bishopric with ministers or curates, who were supported by the common stock of the diocese. For the fund or endowment in each of these districts was common; and whatsoever was received from tithes or the offerings of devotees at the different altars, or by any other means given for religious uses, was made into a general treasure or stock for the ecclesiastical purposes of the whole diocese; and was applied by the bishop in the first place to the maintenance of himself and the college of priests resident with him at the church, and afterwards for distribution in alms among the poor and for the reparation of churches.

This community of residence and interest between the bishop and his attending clergy, who are often termed in the chronicles of those days *episcopi clerus*, constituted the notion of cathedral churches and monasteries in their simplest form. How long this state of things continued does not precisely appear, though Selden expresses an opinion that it was in existence as late as the eighth century. (*History of Tithes*, chap. ix., sect. 2.) It has indeed been asserted by Camden (*Britannia*, p. 160), and was formerly the commonly received opinion, that Honorius, the first archbishop of Canterbury after Augustin, divided his province into parishes about the year 630; but Selden proves satisfactorily that Honorius could not have made a parochial division in the sense in which we now understand the term; and that, if made at all, it must have been such a distribution into districts, then called parishes, as is above described, and which was so far from originating with Honorius, that it must have been nearly as antient as bishoprics.

It seems most probable that the creation of parishes in England was not a simultaneous act, but was the gradual result of circumstances, and was not fully effected till near the time of the Conquest. (Hallam's *Middle Ages*, vol. ii., p. 205.) As Christianity became the universal religion, and as population increased, the means of divine worship supplied by the bishoprics and monasteries became inadequate to the wants of society, and lords of manors began to build upon their own demesnes churches and oratories for the religious purposes of their families and tenants. Each founder assigned a definite district, within which the functions of the minister officiating at his church were to be exercised, and expressly limited the burthen as well as the advantages of his ministry to the inhabitants of that district. As these acts of piety tended to the advance of religion, and were in aid of the common treasury of the diocese, they were encouraged by the bishops, who readily consecrated the places of worship so established, and consented that the minister or incumbent should be resident at his church, and receive for his maintenance, and for the use of that particular church, the tithes and offerings of the inhabitants, as well as any endowment or salary which the founder annexed to it. This endowment or salary usually consisted of a glebe, or a portion of land appropriated to that purpose, which was indeed the only means of providing for the maintenance of the incumbent at a time when almost all the wants of life were supplied from the immediate produce of the earth, and, together with the right of receiving the other ecclesiastical profits which arose within the territory limited by the founder, became the settled revenue of the church, and annexed to it in perpetuity. The last concession made to the lay-founder was probably the patronage or right of presenting the clerk to the church, which, by the primitive constitution, belonged exclusively to the bishop; and when this was obtained, these limited territorities differed in no material respect from our modern parishes. Indeed it can scarcely admit of doubt that our parochial divisions arose chiefly from these lay-foundations, the differences in extent being accounted for by the varying limits appointed for them at their origin. Their names were derived from some favourite saint, from the site, or the lordship to which they belonged, or from the mere fancy of the respective founders. Such appears to have been the origin of the lay parishes; and it is reasonable to conclude that as soon as this practice was established, the bishops and religious houses, in the districts or parishes in which they had reserved to themselves the right of presentation, followed the same course by limiting the ecclesiastical profits of each church to the particular incumbent, and restricting the devotions as well as the offerings of the inhabitants to that church only.

The earliest notice of these lay foundations of parishes is by Bede, about the year 700 (*Hist. Eccl.*, lib. v., c. 4 and 5.) By the end of the eighth century they had become frequent, as clearly appears from the charters of confirmation made to Croyland Abbey, by Bertulph, king of Mercia, in which several churches of lay-foundation are comprehended. In the laws of king Edgar (A.D. 970) there is an express provision that every man shall pay his tithes to the [illegible] antient church or monastery where he hears God's service: [illegible] 'Which I understand not otherwise,' says Selden, 'than [illegible] church or monastery whither usually, in respect of his monastery or his parish, he repaired; that is, his parish church or monastery.' (*History of Tithes*, chap. ix., § 4.)

Although the origin of parishes generally in England is pretty clearly ascertained, the history of the formation of particular parishes is almost wholly unknown. As these divisions originated in an unlettered period, and were too local and obscure to be recorded in the chronicles or general histories of the times, and for the most part too antient to be preserved in any episcopal registers now existing, it would be unreasonable to expect any satisfactory evidence of their particular origin; and as a matter of fact, no evidence whatever can be produced on the subject.

However satisfactory this account of the origin of parishes may be with reference to country parishes, it furnishes no explanation of the origin of parishes in towns—a subject which is involved in great obscurity; and indeed the changes which the latter may be shown to have undergone within time of memory seem to point to a different principle of formation.

The country parishes appear to be nearly the same in name and number at the present time as they were at the time of Pope Nicholas's 'Taxation,' compiled in the reign of Edward I. (A.D. 1288); but in some of the large towns the number of parishes has very considerably decreased. Thus, in the city of London there are at present 108 parishes, though at the time of the 'Taxation' the number was 140; in like manner in Norwich the number has been reduced from 70 in the time of Edward I., to 37 at the present day. In other antient towns, such as Bristol, York, and Exeter, the number does not appear to have materially changed, but the names have been often altered. The particular causes of these variations it would be difficult to trace; but greater changes might reasonably be expected in towns than in the country parishes, in consequence of more frequent fluctuations of wealth and population in the former. Where a decrease has taken place in the number of town parishes in the three last centuries, it is probably to be accounted for by the great reduction since the Reformation in the amount of oblations and what are called *personal* tithes, which in cities were almost the only provision for the parochial clergy.

The size of English parishes varies much in different districts. In the northern counties they are extremely large, forty square miles being no unusual area for a parish; and, generally speaking, parishes in the north are said to average seven or eight times the area of the southern counties. (See Rickman's *Preface to Population Returns of* 1831.) The boundaries of parishes in former times appear to have been often ill-defined and uncertain; but since the establishment of a compulsory provision for the poor by means of assessments of the inhabitants of parishes, the limits have in general been ascertained with sufficient precision.

It is not easy to ascertain the exact number of parishes in England and Wales; for although they have been enumerated on several occasions, the number ascertained has usually depended upon the object and purpose of the particular enumeration. Thus in the returns under the Poor-Law Commission, a parish is generally considered as a place or district supporting its own poor, and from these returns it appears that the total number of such places is 15,400. But in this number are included many subdivisions of parishes, such the townships in the northern counties, which by stat. 13 and 14 Car. II., c. 12, § 21, are permitted to maintain their own poor, and also other places which by act of parliament, though not parishes, have the same privilege. Another difficulty, which has probably affected all the enumerations which have hitherto been made, is the large number of doubtful parishes. It is somewhat uncertain at the present day what circumstances constitute a parish church. In the Saxon times, and for some centuries after the Conquest, the characteristics which distinguished a parish church from what were called field-churches, oratories, and chapels, were the rights of baptism and sepulture. (Selden, *History of Tithes*, chap. ix., 4; Degge's *Parsons' Counsellor*, part i., chap. xii.) But in modern times this line of distinction would include as parish churches almost all chapels-of-ease, and also the churches and parochial chapels erected under the stat. 58 Geo. III., c. 45, 'for building additional churches in populous places.' The various views entertained of the constituents of a parish will in a great measure account for the different results of the several enumerations which have been made; and this is in fact one of the reasons assigned by Camden for the difference between the number of the parish-churches in England and Wales stated to Henry VIII. in 1520, by Cardinal Wolsey, and that stated about a century after in James I., the former being 9407, and the latter 9284. (Camden's *Britannia*, 161-2.) The sum total of the parishes mentioned in Pope Nicholas's 'Taxation' above referred to, as nearly as can be ascertained, appears to be between these two accounts. Blackstone says that the number of parishes in England and Wales had been computed at 10,000, but gives rather a questionable authority for his statement. (*Commentaries*, vol. i., p. 111.) In the Preface to the 'Population Returns' of 1831, above referred to, the number of parishes and parochial chapelries in England and Wales is said to be 10,700, and in Scotland 949; but in the next page, where a summary of the number of parishes in the different dioceses is given, the total is stated as 11,077. Perhaps the number of parishes in England and Wales (meaning by the term simply a district annexed to a church whose incumbent is by law entitled to the perception of tithes in that district) may be taken to be about 11,000.

(See Holland's 'Observations on the Origin of Parishes,' in Hearne's *Discourses*, vol. i., p. 194; and Whitaker's *History of Whalley*, book ii., chap. 1.)

PARK. This term, in its legal signification as a privileged enclosure for beasts of the forest and chase, is at the present day nearly obsolete. Under the antient forest-laws, the franchise of the highest degree was that of a forest, which was *nomen generalissimum*, and contained within it the franchises of chase, park, and warren. The only distinction between a chase and a park was, that the latter was enclosed, whereas a chase was always open, and they both differed from a forest, inasmuch as they had no peculiar courts or judicial officers, nor any particular laws, being subject to the general laws of the forest; or, as Sir Edward Coke maintains, to the common law exclusively of the forest-laws. (4 *Inst.*, 314.) A chase and a park differed from a forest also in the nature of the wild animals to the protection of which each was applied. The beasts of the forest, or beasts of venery, as they were called, were *bestiæ silvestres*, that is, as Manwood explains the phrase (*Forest Laws*, chap. iv., sec. 4), animals such as the hart, hind, hare, boar, and wolf, which 'do keep the coverts and haunt the woods more than the plains.' On the other hand, the beasts of chase or park were *bestiæ campestres*, that is to say, they haunted the plains more than the woods. According to the strict legal meaning of the term, no subject can set up a park without the king's grant, or immemorial prescription, which is presumptive evidence of such a grant. In modern times the term is little known, except in its popular acceptation as an ornamental enclosure for the real or ostensible purpose of keeping fallow deer, interspersed with wood and pasture for their protection and support. (Blackstone's *Commentaries*, vol. ii., p. 38.)

PARK, MUNGO, was born on the 10th of September, 1771, at Fowlshiels, a farm on the banks of the Yarrow, not far from the town of Selkirk. His father, an intelligent and successful farmer, died in the year 1792, but not until Mungo had been fairly launched into professional employment; his mother, who was alive in 1816, was the daughter of a farmer in the vicinity of Fowlshiels. Mungo was the seventh child and third son of a family of thirteen, eight of whom attained the years of maturity.

At the usual age, Mungo was sent to the parochial school at Selkirk. 'He had,' says the writer of the biography prefixed to the complete edition of his Travels, 'shown a great love of reading from childhood, and was indefatigable in his application at school, where he was much distinguished and always at the head of his class. Even at that early age, he was remarked for being silent, studious, and thoughtful; but some sparks of latent ambition occasionally broke forth, and traces might be discovered of that ardent and adventurous turn of mind which distinguished him in after-life.' At the age of fifteen, Mungo Park was apprenticed to Mr. Thomas Anderson, a respectable surgeon in the town of Selkirk, with whom he resided three years, during which time he improved his acquaintance with the classics by occasional attendance at the grammar-school.

In 1789 Park removed to the university of Edinburgh, where he attended, during three successive sessions, the course of lectures prescribed to all who wish to graduate as surgeons. There is nothing left on record of his academical life, except that he devoted considerable attention to botany. Any spontaneous inclination he might feel towards botanical pursuits must have been confirmed and encouraged by associating with his brother-in-law Mr. James Dickson, who, having settled in London as a nurseryman and seedsman, and having attracted the notice of Sir Joseph Banks, had acquired considerable reputation as a scientific botanist. A tour which Park made through the Highlands with this gentleman during one of the summers of his college life contributed much to his progress in the science of botany.

On the completion of his studies at Edinburgh, Park repaired to London. Mr. Dickson introduced him to Sir J. Banks, through whose interest he obtained the appointment of assistant-surgeon to the Worcester, East Indiaman. He sailed in that vessel in the month of February, 1792, on a voyage to Sumatra, and returned to England in the course of the following year. He availed himself of the opportunities afforded him by this voyage to extend his acquaintance with natural history. The third volume of the 'Linnæan Transactions' contains a paper read by Park on the 4th of November, 1794, containing descriptions of eight fishes, not previously described, from the waters of Sumatra, which he represents as the fruits of his leisure hours during his stay on that coast.

At the time of Park's return, the exertions of the African Association had concentrated a strong interest upon that quarter of the globe. Under the guidance of Major Rennell, the Association had collected and published, in a systematic form, a considerable amount of information relative to the interior of Africa. The problem which at that moment more especially engaged their attention was the existence and course of the river mentioned by some antient geographers by the name of Niger. Intelligence had been recently received of the death of Major Houghton, who had been sent out by the Association for the purpose of exploring the course of the Niger, and much difficulty was experienced in finding a successor. Park's attention was naturally attracted to the subject through his connection with Sir Joseph Banks, one of the most active and influential members of the Association. A liberal reward had been offered to any person willing to proceed on the arduous mission who should be found qualified for it. Park had a general passion for travelling; he was in the full vigour of youth; he had some experience of a hot climate; he was not insensible to the distinction to be acquired by a discoverer in African geography: he offered his services to the Association; and, after inquiry into his qualifications, the offer was accepted. Two years elapsed however between his return from India and his departure on his African expedition. With the exception of the time occupied by a short visit to Scotland in 1794, he seems to have resided during the whole of this period in London or the neighbourhood, chiefly occupied in acquiring the knowledge and making the preparations necessary for his undertaking.

He sailed from England on the 22nd of May, 1795, and reached Pisania, a British factory about 200 miles up the Gambia, on the 5th of July. Here he remained several months in the house of Dr. Laidley, learning the Mandingo language, and collecting information concerning the countries he was to visit. For two of these months he was confined by a fever contracted by imprudent exposure during the rainy season.

He left Pisania on the 2nd of December, 1795. After passing through the territories of a number of petty negro chiefs, he was induced, in order to avoid the suspicion of being a spy, which might have attached to him had he passed from the territories of the chief of Kaarta into those of the chief of Bambara, those sovereigns being then at war, to adopt a more northerly route across the territory of Ludamar, then governed by the chief of a predatory horde of nomade Moors. He reached Yarra, the frontier town of this state, on the 18th of February, 1796. Ali, the Moorish chief, detained him a captive till the 1st of July. When Park made his escape he possessed nothing more than a horse with its accoutrements, a few articles of clothing, and a pocket-compass, which he had saved from the Moors by concealing it in the sand. Undismayed by his destitute and lonely condition, he pushed on to the Nil el Abid, or Joliba, which he reached at Sego, after a journey of fifteen days; explored the stream downwards to Silla and upwards to Bammakoe, then crossed a mountainous country to Kamalia, a Mandingo town, which he reached on the 14th of September. Here, 500 miles from the nearest European settlement, his health gave way, undermined by the fever which had attacked him at Pisania, assailed by the vexations and sufferings to which he had been exposed, first as a captive and afterwards as a fugitive, dependent for support upon precarious charity, and exposed to the vicissitudes of the weather. For upwards of a month he was rendered helpless by a fever, among a race which, though alive to human sympathy, could neither think nor feel as he thought and felt. He was detained in the same place five months after his recovery, before he could obtain the means of journeying to the coast. At last, on the 10th of June, 1797, he returned to Pisania, and was received by Dr. Laidley 'as one risen from the dead.' His lonely and toilsome wanderings had occupied upwards of nineteen months.

His unexpected return, the rumours which went abroad regarding his adventures and the strange countries he had visited, excited eager curiosity in the public mind. An abstract of the expedition, prepared by Mr. Bryan Edwards, secretary to the African Association, from materials furnished by the traveller himself, was printed and distributed among the members. To this abstract a memoir by Major Rennell was annexed, consisting of geographical illustrations of Park's journey. It was at the same time announced that a complete narrative would be prepared and published by Park himself. The composition of this work occupied him till the spring of 1799, when it was published. His principal place of residence while engaged upon it was London; and while there he was in constant communication with Major Rennell and Mr. Bryan Edwards, especially the latter. The summer and autumn of 1798 he spent among his relations in Scotland; his head-quarters being Fowlsheils, at that time occupied by his mother and one of his brothers. The accounts subsequently collected from his family represent him as leading then the life of a hard student employed on his papers during the whole of the morning, and allowing himself scarcely any recreation beyond a solitary walk on the banks of the Yarrow. He adopted the abstract of Bryan Edwards as the framework of his book; and Major Rennell's Memoir was added as an appendix. The work was well received; two impressions were rapidly sold off. The profits of publication and the liberal remuneration he received from the Association placed him for the moment in easy circumstances.

In 1799 he retired to his native country, and in the August of that year married the daughter of Mr. Anderson, with whom he had served his apprenticeship. He continued to reside for upwards of two years subsequent to his marriage in the house of his mother, unable or unwilling to settle to any steady employment. At last a favourable opportunity for commencing the practice of his profession occurring in Peebles, he settled with his family in that town, in October, 1801. The practice of a country surgeon in Scotland is attended with much toil and even danger, and the remuneration is very inadequate. Park soon obtained a good share of the business of the neighbourhood, but his profits were inconsiderable. In other respects his situation was agreeable. He was a man of retired habits, who sought and found his happiness in the family circle. There were however in the neighbourhood some minds who could appreciate the intellectual and moral worth that lay beneath his cold exterior. Among these were Dr. Adam Ferguson, at one time professor of moral philosophy in the university of Edinburgh, and author of the 'History of Rome,' and Mr (afterwards Sir Walter) Scott. He also received marked personal attentions from Mr. Dugald Stewart. But the gratification of being appreciated by such men and enjoying their society was no sufficient counterpoise to the harassing reflection that his income was inadequate and his family increasing. His mind too had never ceased to dwell upon foreign adventure. An overture made to him on the part of government, in 1798, to take a part in a survey of New Holland then in contemplation, had been renewed in 1799, but without any other result than that of keeping Park's mind unsettled. In 1801, the prospect of an appointment on the surgical staff at Goree, which had been recently captured from the French, seems to have crossed his mind. In 1[illegible] he learned, by a letter from Sir Joseph Banks, that the Association would probably, in the event of peace, renew their efforts in African discovery, and that Park would certainly be recommended as the most eligible person to be employed. In the autumn of 1803, he received a letter from the office of the colonial secretary of state, requesting his immediate attendance in London. The result of his interview with Lord Hobart was his acceptance of the proposal from government that he should command an expedition of discovery into the interior of Africa, and that the expedition should leave England in the end of February. Some changes in the cabinet caused a postponement. Doubts that began to be entertained of the practicability of the attempt occasioned a further delay. It was not till the 30th of January, 1805, that Park actually sailed from Portsmouth. The interval he had employed, at the suggestion and expense of government, in obtaining a knowledge of the Arabic language, and improving himself in the practice of making astronomical observations.

Park had adopted Mr. Maxwell's opinion, that the Congo and the Niger were one stream; and his plan was, with a supply of merchandise sufficient to defray travelling expenses, and a body of soldiers sufficient to ensure immunity from hostile attacks, to cross from the Gambia to the Niger, and then sail down the stream to the ocean. The expedition, as it started from Pisania, consisted of himself, his brother-in-law Mr. Anderson, surgeon, and Mr. George Scott, draughtsman to the expedition, five artificers from the royal dockyards, Lieutenant Martyn and 35 privates of the Royal African corps stationed at Goree, and Isaaco, a Mandingo, a priest and trader, the guide. Supplies of asses had been purchased at St. Jago and Goree to carry the merchandise. The expedition left Pisania on the 4th of May, 1805.

Park's journal, completed up to the time of his departure from Sansanding, and some letters which he despatched along with it, bring the narrative of his adventures down to that period. To Mrs. Park he wrote, on the 19th of November:—'We have already embarked all our things, and shall sail the moment I have finished this letter.' In his letter to Lord Camden (Lord Hobart's successor in the colonial office), he said:—'I am sorry to say that of forty-four Europeans who left the Gambia in perfect health, five only at present are alive, viz. three soldiers (one deranged in his mind), Lieutenant Martyn, and myself.' He added:—'We had no contest whatever with the natives, nor was any one of us killed by wild animals or any other accidents;' and, again:—'Your lordship will recollect that I always spoke of the rainy season with horror, as being extremely fatal to Europeans, and our journey will furnish a melancholy proof of it.' Isaaco stated on his return to the Gambia that Mr. Park arrived at Foulah Dougou with thirty-three white men; and from Foulah Dougou to Sego (which was eight days' march, but which is generally performed in three days by a negro), they lost twenty-one men by the rains, damps, &c.

At Sansanding, Park dismissed Isaaco, and took, upon his recommendation, a man named Amadi Fatouma to guide him to Haoussa. From this man was procured the only direct contemporary evidence regarding the fate of Park and his companions that has been obtained. His accuracy however is established by a strong body of circumstantial evidence: the traditions of the fate of some white men, collected by Clapperton and Lander, on the spot where Fatouma stated that Park and his companions had perished; muskets with the Tower stamp, seen by Lander at Wowow, and said to have been the property of the white men who perished at Boussa; a book of tables seen by Lander at Boussa, among the leaves of which was found a card of invitation to dinner, addressed to Mr. Park by a Mr. Watson, and dated 'Strand, 9th November, 1804.' The story of Amadi Fatouma, corroborated in its essentials by these circumstances, is briefly this:—that in sailing down the Niger they had repeated encounters with the natives; that on arriving at Yaouri, Fatouma's engagement having terminated, he quitted Mr. Park; that after Mr. Park's departure, the chief of Yaouri informed the king (falsely) that the white men had departed without giving the customary present; that the king in rage imprisoned Fatouma, and sent an armed force to intercept the white men at the narrows of the river; that on his release from prison Fatouma learned from a slave (the only survivor of Park's party) that during a skirmish which ensued the boat was jerked into a rapid, and that the white men, in attempting to make their escape, were drowned.

Thus perished Mungo Park, towards the close of 1805, in the thirty-fifth year of his age. In person he is said to have been tall and athletic. His manner was cold and reserved, approximating in part to that shyness which most persons conscious of their own powers are apt to feel in society when the circumstances of their early life have kept them from mingling with it. His last letter to Mrs. Park (in which he affects a degree of confidence and hope he could not possibly have felt, to allay her apprehensions), and many little incidents in his brief history, show the warmth and strength of his attachments. His judicious conduct while detained by the Moorish chief would alone be sufficient to establish his reputation for the control of his passions; and what he achieved in his first journey, together with the simple striking language of his last letter to Lord Camden, show the power of his determination and perseverance. His acquirements in natural history were necessarily limited; for in Scotland, where he laid their foundation, that branch of knowledge was only beginning to attract attention, and his residences in London were brief, and occupied with other matters. It was not till the eve of his departure on his second journey that he acquired the Arabic language, not only the best medium of communication with the Moors and Arabs, but the only key to the civilization of Africa, such as it is. His acquaintance with astronomy does not seem, even at the time of his second journey, to have gone beyond the power of making with accuracy the necessary observations for the ascertaining of latitudes and longitudes; and at the time of his first journey, seems to have been limited to the power of observing for the latitude with the sextant. On his first journey he lost all his instruments, with the exception of a pocket-compass, when taken prisoner by the Moors: on his second journey he was better provided; but his only chronometer seems to have been very defective. These deficiencies however in acquirements and apparatus were in a great extent counterbalanced by a calm courageous self-possession, an unwearied power of observation, and a modest scrupulous veracity that enables us to rely upon his statements as in no instance exaggerated.

Almost the whole of the country which he traversed may be regarded as having been before him unvisited by Europeans, and nothing of any moment has been added to our knowledge of it since his death. His ignorance of Arabic on his first journey exposed him to misappreciate the Arabs; but his detention in a Mandingo village enabled him to master the domestic life of the negroes and their civil and economical organization. His meteorological and botanical observations are valuable: his geological are less so. Walckenaer and his echo Bowditch have impugned the trustworthiness of his observations for latitude on his second journey, on account of an entry in his journal, '31st April,' that month having only 30 days. But Oltmanns has satisfactorily established, in an elaborate and able paper in the 'Transactions of the Berlin Royal Academy,' by comparison of the *data* stated in Park's journal with the Ephemerides of the 'Nautical Almanac' for 1805, that by whatever oversight he may have written '31st April,' he was perfectly correct in his reckoning when he made his observations. On the other hand Oltmanns has pointed out a circumstance which vitiates Park's calculations of his observations for longitude: the confusion arising out of the substitution, without sufficiently explicit warning, in 1805, in the Ephemerides of the 'Nautical Almanac,' of *mean time* for apparent time in the tables for the eclipses of Jupiter's satellites. Unluckily Park has stated only in one instance (Bee-creek) the whole of the *data* upon which his longitudes were calculated; and consequently in that one instance alone can his oversight be corrected. Only one opinion can be entertained of the sound judgment displayed by Park in his conduct during his first journey as a solitary traveller. His judgment in the estimation of obstacles and the calculation of forces by which they might be overcome in planning the expedition in which he perished, is more open to challenge: but he did not seek to shun the consequences. A question regarding the degree of credit due to him in a literary point of view for the narrative of his first travels, seems really of little consequence. It is clear that, unaccustomed to literary composition, he formed his book upon the model of Bryan Edwards's abstract; but that it was his own composition there seems no good reason to doubt. Either owing to natural good taste, or a lucky want of facility in sentence-turning, his style is far less turgid than that of his model.

Park left a widow and three children. Mrs. Park died in the month of February in the present year: it is believed that none of her children have survived her.

tive of Discoveries in Central Africa, &c., Denham and Clapperton, 1 vol. 4to., London, 1826; *Journal of a Second Expedition to Africa, &c.*, Clapperton, 1 vol. 4to., London, 1829; *Journal of an Expedition to explore the Course and Termination of the Niger*, by Richard and John Lander, 3 vols. small 8vo., London; Oltmanns, *Ueber die Nichtigkeit einiger Verbesserungen welche mit Mungo Park's letzten Breitenbestimmungen in Africa vorgenommen sind. Abhandlungen der Königlichen Academie der Wissenschaften zu Berlin aus dem Jahre* 1831.)

PARK OF ARTILLERY, an assemblage of the heavy ordnance belonging to an army, with its carriages, ammunition waggons, and stores, on ground contiguous to that which is occupied by the troops when encamped.

The park is formed in the immediate vicinity of roads by which the artillery may be readily moved to any spot where its service may be required: it is usually in rear of the troops, the guns being arranged in one line if the ground will permit; and if the army is to remain for some time in its position, the park is, for preventing the intrusion of improper persons, surrounded by chevaux-de-frise or other obstacles. At the siege of a fortress the park is situated between the army and the place, and it should be beyond the range of the artillery of the latter. If possible, it may be behind some rising ground, and on a spot from whence the artillery may be speedily brought up to the trenches or batteries.

In determining the extent of a park, 10 feet along the front are allowed for each gun; and since the limber and the ammunition waggon are placed in rear of the gun in one line, and in the direction of the depth, the latter must necessarily be sufficient for these, as well as to permit the horses to be attached to the carriages. The guns of each different calibre are commonly placed in that part of the park which is nearest to the point of ground to be occupied by them when in position; but the artillery is sometimes arranged in the park according to its calibre, the heaviest being on the right of the line. The muzzles are usually turned towards the front of the line; but if the guns are liable to be suddenly called for, the shafts of the limbers and the trails of the guns are then placed in that direction for the sake of a more speedy removal.

A quarter-guard, as it is called, is posted at a certain distance from and opposite the middle of the front of the park: the gunners' tents are arranged along the two flanks; those of the commissioned officers are in the rear; and behind them, generally, the horses are picketed in one line or more, parallel to that of the guns.

At the siege of a fortified place, the stores of gabions, fascines, and other materials used in the operations of the attack, as well as the spades, axes, and other tools for executing the trenches, raising batteries, or cutting down obstacles, are deposited in a particular place, for the purpose of keeping them in security and near at hand when wanted: this constitutes what is called the engineers' park. Like that of the artillery, it is situated where it may be concealed from the view of the enemy, and where means exist for a ready communication, at all times, both with the camp in the rear and with the trenches in front. The necessity of having the parks as far as possible from the place besieged, may be conceived from the fact that, at the siege of Badajos, in consequence of their being within range of artillery, the shot and shells from the town often fell into them; and once the cavalry of the garrison, in a sortie, actually rode through the engineers' park, on which occasion the whole store of materials collected by the besiegers might have been destroyed.

In the French service two parks were sometimes formed for the artillery; a great park for the guns, carriages, &c., and a small park to contain the working places for the carpenters and armourers, with the materials for making the repairs which are constantly required during a campaign.

PARKER, MATTHEW, born 1504, died 1575, a very eminent name in the catalogue of illustrious Englishmen. That he attained to the highest dignity in the English church is not the sole proof of his claim to be so spoken of; but that he was an eminent scholar as well as great churchman, a cultivator of historical literature as well as a great proficient in theological learning, and that he was archbishop of Canterbury in that critical period when the English Protestant or Reformed Church was in its infancy, and that he fulfilled the purposes of those who placed him in that high dignity by the skill with which he conducted the very difficult operations necessary at that time for its formation in a certain order and its perpetual existence.

Parker was a native of the city of Norwich, educated in Corpus Christi College, Cambridge, being intended for the church, and was so diligent in his studies, especially of the Scriptures and the fathers, that before he was thirty he was fixed upon by Wolsey to be one of his professors in the college which he meant to found at Oxford. This honour however Parker declined, probably in consequence of having attached himself to the reforming party in the church, with some of the more eminent of whom he was by that time become intimate. At this early period of his life he had a licence to preach.

We must pass lightly over the succession of his preferments during the reigns of Henry VIII. and Edward VI. Beside having two or three benefices, he was made an archdeacon in 1526; dean of the college of Stoke Clare, his favourite piece of preferment, 1535; one of the king's chaplains, 1537; master of Corpus Christi College, 1544; dean of Lincoln, 1552. In 1545 he was vice-chancellor of his university.

He took a wife in 1547. One of the measures of the reign of Queen Mary, by which it was hoped to re-establish the church in its former state and order, was to deprive the married clergy of all their benefices and preferments. This removed from the church at one stroke no small number of the more zealous reforming divines. It is marvellous that Parker fared no worse in the reign of Mary. It does not appear that he even found it necessary to leave England, but rather that he continued to live quietly in the eastern counties, pursuing his theological studies.

Very soon after the death of Mary, and when Elizabeth had ascended the throne, he was summoned from his retirement, and induced to accept at once the high dignity of archbishop of Canterbury. His consecration took place on December 17, 1559.

He was archbishop more than fifteen years, during which time he was assiduously employed in watching over the interests of the new-formed church, and in giving it that consistency and order which the church of England has since maintained. We cannot enter into the detail of what he did, but we must not forbear to mention that the preparation of the great work called the Bishops' Bible was performed under his auspices, and that the work was completed in 1568. Whoever wishes for more information respecting the labours of this eminent father of the English Protestant church, and the minute particulars of his history and character, may be abundantly satisfied by consulting the folio Life of him written by the indefatigable Strype.

Parker is not to be estimated solely by what he did as an ecclesiastic. He collected a large library of valuable manuscripts, which he gave to his college in Cambridge, where he founded also divers fellowships and scholarships. The manuscripts still remain, having been very carefully preserved. There is a minute and excellent catalogue of them in print by Nasmith, who made also a catalogue of the manuscripts in the Public Library at Cambridge, which has never been printed. Parker gave encouragement to Saxon literature by the publication of a Saxon homily. He caused to be printed also the Chronicles of Matthew of Westminster and Matthew Paris; and there is an original treatise, 'De Antiquitate Britannicæ Ecclesiæ,' which is usually attributed to him, and in the preparation of which he had no doubt much concern.

PARKER, SAMUEL, born 1640, died 1687, a prelate of the English church, was of Puritan extraction, and was remarked for certain Puritan extravagancies, when, as a young man, he entered Wadham College, Oxford. But at Oxford he became acquainted with several persons of a very different turn of mind, and particularly with Dr. Ralph Bathurst, who is said by the writers of his Life to have been chiefly instrumental in drawing him away from a party which was marked for persecution and extinction. He had an active pen, which he employed about the time of the Restoration, and for a few succeeding years, in repeated attacks on the Puritan, or, as it then was become, the Non-conforming party. The controversy is almost forgotten, and we think it needless to recount the titles of the tracts.

He was favoured and promoted in the church. In [illegible] he was made chaplain to Archbishop Sheldon, and in [illegible] he was a prebendary of Canterbury, and had the livings Ickham and Chartham.

When king James II. contemplated the re-union of England to the general church, with its head in the Roman pontiff, he looked among the English divines for persons who might be willing to assist in his designs, and, amongst other persons, he fixed upon Parker, who was made by him bishop of Oxford, in January, 1686; and when Hough was deprived of the presidentship of Magdalen College, it was given to Parker. It is said that he was strongly inclined to popery, but how far he would have gone with the king in that direction cannot well be fully determined, as his life was cut short soon after he had obtained this dignity. He died at Magdalen College, on May 20, 1687.

The only writing of Bishop Parker of any permanent reputation is a treatise entitled 'De Rebus sui Temporis Commentarius.' This treatise was not published till 1726, when it was given to the world by his son, a second Samuel Parker, an eminent non-juring divine.

PARKHURST, JOHN, was the second son of John Parkhurst, Esq., of Catesby in Northamptonshire. He was born in June, 1728, and educated at Rugby Grammar-school, and afterwards at Clare Hall, Cambridge, where he took the degree of B.A. in 1748, and that of M.A. in 1752. He was for some years a fellow of his college. He took orders in the church of England, but never obtained any preferment, having succeeded to a considerable estate, which rendered him independent. He acted, without receiving any salary, as curate of the church at Catesby, the preferment of which was in his own gift.

In 1754 he married Susanna Myster, daughter of John Myster, Esq., of Epsom in Surrey. She died in 1759, leaving him a daughter and two sons. In 1761 he married Millicent Northey, by whom he had a daughter, Mrs. Thomas, who became eminent for her learning: she wrote her father's epitaph in Epsom church.

Parkhurst died at Epsom, on the 21st of March, 1797. He was a man of great integrity and firmness of character. He always lived in retirement, though he possessed qualities which fitted him to shine in society. In spite of a weak constitution, he was a most laborious student, rising for many years at five o'clock in the morning.

His first work was 'A Serious and Friendly Address to the Rev. John Wesley,' remonstrating against the doctrine of the faith of assurance as held by that divine: it was published in 1753. In 1762 he published the first edition of his 'Hebrew and English Lexicon, without Points,' with a Hebrew grammar, which has passed through several editions. His 'Greek and English Lexicon to the New Testament,' with a Greek grammar, appeared in 1769. Of this work there are several editions, both in 4to. and 8vo.: the first of the octavo editions was edited by his daughter, Mrs. Thomas. A new edition, by the Rev. Hugh James Rose, D.D., was published in 1829. The only other work published by Mr. Parkhurst was 'The Divinity and Preexistence of our Lord and Saviour Jesus Christ demonstrated from Scripture, in answer to the First Section of Dr. Priestley's Introduction to the History of Early Opinions concerning Jesus Christ,' Lond., 1787, 8vo. Dr. Priestley replied to this work in 'A Letter to Dr. Horne.'

Parkhurst's lexicons have enjoyed a considerable reputation from the time of their first appearance. They are disfigured by many fanciful and ridiculous etymologies, and they bear traces of the Hutchinsonian opinions of their author. They are now superseded by the works of Gesenius, Winer, Wahl, Bretschneider, and Robinson.

(*Chalmers's Biographical Dictionary.*)

PARKIA, a genus of plants of the natural family or tribe of Mimoseæ, named by Mr. Brown, the chief of botanists, in honour of the great African traveller Mungo Park. The genus contains only a few unarmed trees, which are found on the west coast of Africa, the peninsula of India, Silhet, and in the islands to the eastward of the Bay of Bengal. Parkia is distinguished among the Mimosa-like Leguminosæ by the tubular 5-cleft calyx and the corolla with 5 distinct petals having a more or less imbricate æstivation; stamens 10, hypogynous, monadelphous. Legume many-seeded, 2-valved, with a farinaceous pulp around and between the seeds. Inflorescence an axillary peduncled and club-shaped spike.

P. Africana is the *Nitta* or *Doura* tree of Soudan. The farinaceous matter surrounding the seeds is eaten, and also made into a pleasant drink when steeped in water. The seeds are roasted as coffee is with us, then bruised and allowed to ferment in water. When they begin to become putrid, they are well washed and pounded, and the powder is made into cakes resembling chocolate, which form an excellent sauce for all kinds of meat. (Brown, in Denham.) A species of this genus, the Mimosa pedunculata of Roxburgh, is said by him to be similarly valued by the Malays, that is, they eat the mealy matter which surrounds the seeds, as well as the seeds themselves, which are said to taste like garlic.

PARKINSO'NIA ACULEATA, or the Barbadoes Flower-Fence, is a well known West Indian shrub, very generally employed in such climates as an ornamental plant, and especially for the construction of hedges, for which its strong spines render it well adapted. It has long pinnated leaves, with a winged petiole, and grows as much as twelve or fifteen feet high. The flowers are large, yellow, very numerous, and a little variegated with red spots, and are succeeded by long narrow knotted pods. When in flower it is said to be one of the most splendid objects in the vegetable kingdom. It has long been cultivated in this country, but it seldom flowers, probably from not having room enough given it to grow in. The seeds are said to possess febrifugal qualities.

PARLIAMENT, IMPERIAL, the legislature of the United Kingdom of Great Britain and Ireland, consisting of the king or queen [KING], the lords spiritual and temporal [LORDS, HOUSE OF], and the knights, citizens, and burgesses [COMMONS, HOUSE OF] in parliament assembled.

The word is generally considered to be derived from the French, 'parler,' to speak. 'It was first applied,' says Blackstone, 'to general assemblies of the states under Louis VII. in France about the middle of the twelfth century.' The earliest mention of it in the statutes is in the preamble to the statute of Westminster, A.D. 1272.

Origin and Antiquity of Parliament.

The origin of any antient institution must be difficult to trace, when in the course of time it has undergone great changes; and few subjects have afforded to antiquaries more cause for learned research and ingenious conjecture than the growth of our parliament into the form which it had assumed when authentic records of its existence and constitution are to be found. Great councils of the nation existed in England both under the Saxons and Normans, and appear to have been common amongst all the nations of the north of Europe. They were called by the Saxons *michel-synoth*, or great council; *michel-gemote*, or great meeting; and *witena-gemote*, meeting of wise men—by the last of which they are now most familiarly known.

The constitution of these councils cannot be known with any certainty, and there has been much controversy on the subject, and especially as to the share of authority enjoyed by the people. Different periods have been assigned for their admittance into the legislature. Coke, Spelman, Camden, and Prynne agree that the commons formed part of the great synods or councils before the Conquest; but how they were summoned, and what degree of power they possessed, is a matter of doubt and obscurity. 'The main constitution of parliament, as it now stands,' says Blackstone, 'was marked out so long ago as the seventeenth year of King John, A.D. 1215, in the great charter granted by that prince, wherein he promises to summon all archbishops, bishops, abbots, earls, and greater barons [BARONS] personally, and all other tenants in chief under the crown by the sheriff and bailiffs, to meet at a certain place, with forty days' notice, to assess aids and scutages when necessary; and this constitution has subsisted, in fact at least, from the year 1266, 49 Hen. III., there being still extant writs of that date to summon knights, citizens, and burgesses to parliament.' A statute, also, passed 15 Edw. II. (1322), declares that 'the matters to be established for the estate of the king and of his heirs, and for the estate of the realm and of the people, should be treated, accorded, and established in parliament, by the king and by the assent of the prelates, earls, and barons, and the commonalty of the realm, *according as had been before accustomed*.' In reference to this statute Mr. Hallam observes 'that it not only establishes by a legislative declaration the present constitution of parliament, but recognises it as already standing upon a custom of some length of time.' (*Const. Hist.*, 5.)

Constituent Parts of Parliament.

These have been treated of in separate articles, and nothing more will be attempted in this place than a brief analysis, which will bring the whole under one view. Of the king (or queen), the first in rank, nothing need be repeated.

The House of Lords is at present composed of—

Lords Spiritual.

2 archbishops (York and Canterbury)
24 English bishops
4 Irish representative bishops

Total, 30

Lords Temporal.

3 dukes of the blood royal
21 dukes
20 marquesses
113 earls
20 viscounts
211 barons
16 representative peers of Scotland
28 representative peers of Ireland

Total, 432

The number has been greatly augmented from time to time, and there is no limitation of the power of the crown to add to it by further creations. The introduction of the representative peers of Scotland and Ireland was effected on the union of those kingdoms respectively with England. The former are elected by the hereditary peers of Scotland descended from Scottish peers at the time of the Union, and sit for one parliament only; the latter are chosen for life by the peers of Ireland, whether hereditary or created since the Union. The power of the crown to create Irish peers is limited by the Act of Union, so that one only can be created when three of the peerages of Ireland have become extinct.

The present composition of the House of Commons is as follows:—

England and Wales.

159 knights of shires
341 citizens and burgesses

Total, 500

Scotland.

30 knights of shires
23 citizens and burgesses

Total, 53

Ireland.

64 knights of shires
41 citizens and burgesses

Total, 105
Total of the United Kingdom, 658.

An account of the changes effected in the parliamentary constituencies at different times, more particularly by the Reform Act, and a full view of the present system of representation, is given in the article Commons, House of.

The lords and commons originally were one assembly, but the date of their separation is not known. Sir Edward Coke states that he had seen a record, 30 Hen. I. (1130), of their degrees and seats as one body, and affirms that the separation took place at the desire of the commons. (13 *State Trials*, 1410.) Elsynge avers that 'the commons ever had a place for their consultation apart from the lords, though they did often meet and sit together in one room,' and gives several precedents in support of his position. (*Manner of Holding Parliaments*, pp. 101-104, 155.)

Power and Jurisdiction of Parliament.

1. **Legislative Authority collectively.**—The authority of parliament extends over the United Kingdom and all its colonies and foreign possessions. There are no other limits to its power of making laws for the whole empire than those which are common to it and to all other sovereign authority, the willingness of the people to obey, or their power to resist them. It has power to alter the constitution of the country, for that is the constitution which the last act of parliament has made. It may take away life by acts of attainder, and make an alien be as a natural-born subject.

Parliament does not in the ordinary course legislate directly for the colonies. For some, the queen in council legislates, and others have legislatures of their own, and propound laws for their internal government, subject to the approval of the queen in council; but these may afterwards be repealed or amended by direct statutes from this country. Their legislatures and their laws are both subordinate to the supreme power of the mother country. The constitution of Lower Canada is at the present moment (April, 1840) suspended; and a provisional government, with legislative functions and great executive powers, has been established by the British parliament. Slavery was abolished by an act of parliament in 1833 throughout all the British possessions, whether governed by local legislatures or not; but certain measures for carrying into effect the intentions of parliament were left for subsequent enactment by the local bodies, or by the queen in council. The House of Assembly of Jamaica, the most antient of our colonial legislatures, had neglected to pass an effectual law for the regulation of prisons, which became necessary upon the emancipation of the negroes, and parliament immediately interposed and passed a statute for that purpose. The Assembly were indignant at the interference of the mother country, and neglected their functions, until an act was passed by the imperial parliament suspending the constitution of Jamaica unless they resumed them.

The power of imposing taxes upon colonies for the support of the parent state was attempted to be exercised by parliament upon the provinces of North America; but that attempt was the immediate occasion of the severance of that great country from our own. The injustice and hardship of colonial taxation must be admitted; but the legal power of parliament to impose such taxes can only be restrained by its own acts conferring constitutions and privileges upon the colonies, which are all subject to its authority.

There are some subjects indeed upon which parliament, in familiar language, is said to have no right to legislate; such for instance as the Church; but no one can intend more by that expression than that it is inexpedient to make laws as to such matters. The very prayers and services of the Church are prescribed by statute. Parliament has changed the professed religion of the country, and has altered the hereditary succession to the throne. To conclude, in the words of Sir Edward Coke, the power of parliament 'is so transcendent and absolute, that it cannot be confined, either for causes or persons, within any bounds.'

2. **Distribution of Powers between King, Lords, and Commons.**—Custom and convenience have assigned to different branches of the legislature peculiar powers. These are subject to any limitation or even transference which parliament may think fit. The king swears at the coronation to govern 'according to the statutes in parliament agreed upon,' and these of course may be altered. Prerogatives of the crown which have ever been enjoyed might yet be taken away by the king, with the consent of the three estates of the realm. The king sends and receives ambassadors, enters into treaties with foreign powers, and declares war or peace, without the concurrence of lords and commons; but these things he cannot do without the advice of his ministers, who are responsible to parliament. Without entering into a view of his general prerogatives, which are treated of elsewhere [King], it will be necessary to advert to certain parliamentary functions exercised by him, and which are most important in the conduct of legislation.

Summons.—It is by the act of the king alone that parliament can be assembled. There have been only two instances in which the lords and commons have met of their own authority, namely, previously to the restoration of King Charles II. and at the Revolution in 1688.

The first act of Charles II.'s reign declared the lords and commons to be the two houses of parliament, notwithstanding the irregular manner in which they had been assembled, and all their acts were confirmed by the succeeding parliament summoned by the king; which however qualified the confirmation of them by declaring that 'the manner of the assembling, enforced by the difficulties and exigencies which then lay upon the nation, is not to be drawn into example.' In the same manner the first act of the reign of William and Mary declared the convention of lords and commons to be the two houses of parliament, as if they had been summoned according to the usual form; and the succeeding parliament recognised the legality of their acts. But although the king may determine the period for calling parliaments, his prerogative is restrained within certain limits; as he is bound by statute to [illegible] once within three years after the determination of any parliament; while the practice of providing money for the public service by annual enactments renders it compulsory upon him to meet parliament every year.

There is one contingency upon which the parliament may meet without summons, under the authority of an act of parliament. It was provided by the 6 Anne, c. 7, that 'in case there should be no parliament in being at the time of the demise of the crown, then the last preceding parliament should immediately convene and sit at Westminster, as if the said parliament had never been dissolved.' By the 37 Geo. III., c. 127, a parliament so revived would only continue in existence for six months, if not sooner dissolved.

As the king appoints the time and place of meeting, so also at the commencement of every session he declares to both houses the cause of summons by a speech delivered to them in the house of lords by himself in person, or by commissioners appointed by him. Until he has done this, neither house can proceed with any business.

The causes of summons declared do not make it necessary for parliament to consider them only, or to proceed at once to the consideration of any of them. After the speech, any business may be commenced, and the commons, in order to prove their right to act without reference to any authority but their own, invariably read a bill a first time *pro formâ* before they take the speech into consideration. Other business is also done very frequently at the same time. New writs are issued for places which have become vacant during the recess, returns are ordered, and even addresses are presented on matters unconnected with the speech. In the present session (1840) a question of privilege, arising out of the action of Stockdale against the printers of the house, was entertained before any notice was taken of her Majesty's speech.

Prorogation and Adjournment.—Parliament, it has been seen, can only commence its deliberations at the time appointed by the king; neither can it continue them any longer than he pleases. He may prorogue parliament by having his command signified in his presence by the lord chancellor or speaker of the house of lords to both houses, or by writ under the great seal, or by commission. The effect of a prorogation is at once to suspend all business until parliament may be summoned again. Not only are the sittings of parliament at an end, but all proceedings pending at the time, except impeachments by the commons, are quashed. A bill must be renewed after a prorogation, as if it had never been introduced, though the prorogation be for no more than a day. William III. prorogued parliament from the 21st October, 1689, to the 23rd, in order to renew the Bill of Rights, concerning which a difference had arisen between the two houses that was fatal to it. Owing to a rule that a bill cannot be passed in either house twice in the same session, a prorogation has been resorted to in other cases to enable a second bill to be brought in.

Adjournment is solely in the power of each house respectively. It has not been uncommon indeed for the king's pleasure to be signified, by message or proclamation, that both houses should adjourn. Either of them however may decline complying with what can be considered as no more than a request. Business has frequently been transacted after the king's desire has been made known, and the question for adjournment put in the ordinary manner.

Dissolution.—The king may also put an end to the existence of parliament by a dissolution. He is not however entirely free to define the duration of a parliament, for after seven years it ceases to exist under the statute of George I., commonly known as the Septennial Act. Before the Triennial Act, 6 Wm. and Mary, there was no limit to the continuance of a parliament, except the will of the king. Parliament is dissolved by proclamation, after having been prorogued to a certain day. This practice, according to Hatsell, 'which has now been uniform for above a century, has probably arisen from those motives that are suggested by Charles I., in his speech in 1628, "that it should be a general maxim with kings themselves only to execute pleasing things, and to avoid appearing personally in matters that may seem harsh and disagreeable."'

In addition to these several powers of calling a parliament, appointing its meeting, directing the commencement of its proceedings, determining them for an indefinite time by prorogation, and finally of dissolving it altogether, the crown has the creation of one entire branch of the legislature; together with other parliamentary powers, which will hereafter be noticed in treating of the functions of the two houses.

The judicial functions of the lords and their right to pass bills affecting the peerage which the commons may not amend, are the only properties peculiar to them, apart from their personal rights and privileges.

Taxation.—The chief powers vested in the house of commons are those of imposing taxes and voting money for the public service. Bills for these purposes can only originate in that house, and the lords may not make any alterations in them, except for the correction of clerical errors. On the opening of parliament, the king directs estimates to be laid before the house, but the amount may be varied by the commons at pleasure. Grants distinct from those proposed in the estimates cannot be made without the king's recommendation being signified. The commons will not allow the right of the lords to insert in a bill any pecuniary penalties or to alter the amount or application of any penalty imposed by themselves; but the rigid assertion of this rule was found to be attended with much inconvenience, and a standing order was made in 1831, directing the Speaker in each case to report whether the object of the lords appears to be 'to impose, vary, or take away any pecuniary charge or burthen on the subject,' or 'only to relate to the punishment of offences, and the house shall determine whether it may be expedient in such particular case to insist upon the exercise of their privilege.'

Right of determining Elections.—Another important power peculiar to the commons is that of determining all matters touching the election of their own members, and involving therein the rights of the electors. Upon the latter portion of their right a memorable contest arose between the lords and commons in 1704. Ashby, a burgess of Aylesbury, brought an action at common law against the returning-officers of that town for having refused to permit him to give his vote at an election. A verdict was obtained by him, but a judgement was given against him in the Queen's Bench, which was reversed by the house of lords upon a writ of error. The commons declared that 'the determination of the right of election of members to serve in parliament is the proper business of the house of commons, which they would always be very jealous of, and this jurisdiction of theirs is uncontested; that they exercise a great power in that matter, for they oblige the officer to alter his return according to their judgment; and that they cannot judge of the right of election without determining the right of the electors, and if electors were at liberty to prosecute suits touching their right of giving voices in other courts, there might be different voices in other courts, which would make confusion, and be dishonourable to the house of commons; and that therefore such an action was a breach of privilege.' In addition to the ordinary exercise of their jurisdiction as regarded the right of elections, the commons relied upon an act of the 7 Will. III., c. 7, by which it had been declared, that 'the last determination of the house of commons concerning the right of elections is to be pursued.' On the other hand, it was objected that 'there is a great difference between the right of the electors and the right of the elected: the one is a temporary right to a place in parliament *pro hâc vice*; the other is a freehold or a franchise. Who has a right to sit in the house of commons, may be properly cognisable there; but who has a right to choose, is a matter originally established, even before there is a parliament. A man has a right to his freehold by the common law, and the law having annexed his right of voting to his freehold, it is of the nature of his freehold, and must depend upon it. The same law that gives him his right must defend it for him, and any other power that will pretend to take away his right of voting, may as well pretend to take away the freehold upon which it depends.' These extracts from the Report of a Lords' Committee, 27 March, 1704, upon the conferences and other proceedings in the case of Ashby and White, give an epitome of the main arguments upon which each party in the contest relied. The whole of this Report, together with another of the 13 March, may be read with great interest.

Encouraged by the decision of the house of lords, five other burgesses of Aylesbury, now familiarly known as 'the Aylesbury men,' commenced actions against the constables of their town, and were committed to Newgate by the house of commons for a contempt of their jurisdiction.

They endeavoured to obtain their discharge on writs of *habeas corpus*, but did not succeed. The commons declared their counsel, agents, and solicitors guilty of a breach of privilege, and committed them also. Resolutions condemning these proceedings were passed by the lords; conferences were held, and addresses presented to the queen. At length the queen came down and prorogued parliament, and thus put an end to the contest and to the imprisonment of the Aylesbury men and their counsel.

The question which was agitated at that time has never since arisen. The commons have continued to exercise the sole right of determining whether electors have had the right to vote while inquiring into the conflicting claims of candidates for seats in parliament, and specific modes for trying the right of election by the house have been prescribed by statutes, and its determination declared to be 'final and conclusive in all subsequent elections, and to all intents and purposes whatsoever.'

Connected with the right of the commons to adjudicate upon all matters relating to elections, may be mentioned their power over the eligibility of candidates. John Wilkes was expelled, in 1764, for being the author of a seditious libel. In the next parliament (February 3, 1769) he was again expelled for another libel; a new writ was ordered for the county of Middlesex, which he represented, and he was re-elected without a contest; upon which it was resolved, on the 17th February, 'that having been in this session of parliament expelled this house, he was and is incapable of being elected a member to serve in this present parliament.' The election was declared void, but Mr. Wilkes was again elected, and his election was once more declared void, and another writ issued. A new expedient was now tried. Mr. Luttrell, then a member, accepted the Chiltern Hundreds, and stood against Mr. Wilkes at the election, and, being defeated, petitioned the house against the return of his opponent. The house resolved that although a majority of the electors had voted for Mr. Wilkes, Mr. Luttrell ought to have been returned, and they amended the return accordingly. Against this proceeding the electors of Middlesex presented a petition, without effect, as the house declared that Mr. Luttrell was duly elected. The whole of these proceedings were severely condemned, and on the 3rd of May, 1782, the resolution of the 17th of February, 1769, was ordered to be expunged from the journals as 'subversive of the rights of the whole body of electors of this kingdom.' A resolution similar to that expunged had been passed in the case of the unfortunate Hall, in 1580, as part of the many punishments inflicted upon him, which we shall have occasion to mention.

Oaths.—The power of administering oaths exercised by the lords is not claimed by the house of commons. They formerly endeavoured to attain the end supposed to be secured by the administration of an oath, by resorting to the authority of justices of the peace who happened to be members of their own body; but all such expedients have long since been abandoned, and witnesses guilty of falsehood are punished by the house for a breach of privilege, not being amenable to the laws regarding perjury. Election committees have power by statute to administer oaths, and witnesses giving false evidence are guilty of perjury.

3. Privileges.—Both houses of parliament possess various rights and privileges for the maintenance of their collective authority, and for the protection, convenience, and dignity of individual members. At the commencement of each parliament, the Speaker, on behalf of the commons, has 'laid claim to them of the king' since the reign of Henry VIII., but they appear to have been always enjoyed with equal certainty before that time. Some of them have been subsequently confirmed, modified, and even abolished by acts of parliament, but the petition of the Speaker remains unchanged, and prays for some which have been disallowed by law since the original form was adopted.

Commitment and Fines.—The power of commitment for contempt has always been exercised by both houses. It has been repeatedly brought under the cognizance of the courts, and allowed without question. Mr. Wynn, in his 'Argument,' states that there are upwards of one thousand cases of commitment by the house of commons to be found in their Journals since 1547. Breaches of privilege committed in one session may be punished by commitment in another, as in the well-known case of Murray, in 1751-2, who was imprisoned in Newgate for a libel until the end of the session, and on the next meeting of parliament was again ordered to be committed; but he had absconded in the meanwhile. Contempts of a former parliament may also be punished. The lords may commit for a definite period beyond the duration of the session or parliament; but a commitment by the commons holds good only until the close of the session.

The house of lords, in addition to the power of commitment, may impose fines. This privilege is not exercised by the commons, although there is a case in D'Ewes's 'Journals of Queen Elizabeth,' in which Mr. Hall, a member who had incurred their displeasure, by publishing a work 'very slanderous and derogatory to the general authority, power, and state of the house, and prejudicial to the validity of its proceedings in making and establishing laws,' was ordered to 'pay a fine to the queen of five hundred marks.' The house at the same time assumed a power not found to have been exercised in other cases. It committed Mr. Hall to the Tower, and ordered that he should remain there for 'six months, and until he should made retraction of the book.' This punishment was commitment for a time certain without reference to the continuance of the session, and, in the event of a refusal to retract the book, amounted to perpetual imprisonment. A practice still exists which partakes of the nature of a fine. There are certain fees payable by persons committed to the custody of the serjeant-at-arms, and it is usual on discharging them out of custody to attach the condition of the 'payment of the fees.' These fees are occasionally remitted under particular circumstances—in one case, on account of the poverty of the prisoner.

Freedom of Speech.—Freedom of speech is one of the privileges claimed by the Speaker on behalf of the commons; but it has long since been confirmed as the right of both houses of parliament by statutes. It was acknowledged in an act in the reign of Henry VIII., by which the proceedings of the stannary court with respect to Richard Strode, a member, who was fined and imprisoned by that court for having proposed a bill to regulate the tinners in Cornwall, were declared illegal, and the repetition of similar encroachments upon the privilege of parliament provided against. The language however was thought ambiguous, and it was by limiting its operation to the case of Strode that a judgment was obtained in the King's Bench against Sir John Elliot, Denzil Hollis, and Valentine, in the reign of Charles I. A true interpretation of the law was subsequently established by resolutions of both houses of parliament, and by a formal reversal of this judgment by the house of lords. The most solemn recognition of the privilege is contained in the Bill of Rights, which declares 'that the freedom of speech and debates and proceedings in parliament ought not to be impeached or questioned in any court or place out of parliament.'

There are however certain legal incidents to this privilege, which it is necessary to notice. The law presumes that everything said in parliament is with the view to the public good and necessary for the conduct of public business; but should the member publish his speech, he is viewed as author only, and if it contain libellous matter, he will not be protected by the privilege of parliament. In 1795, an information was filed against Lord Abingdon for libel. His lordship had accused his attorney, in parliament, of improper conduct in his profession. He afterwards published his speech in several newspapers at his own expense. His lordship pleaded his own cause, and contended that he had a right to print what he had, by the law of parliament, a right to speak; but Lord Kenyon said 'that a member of parliament had certainly a right to publish his speech, but that speech should not be made a vehicle of slander against any individual; if it was, it was a libel.' In 1813, a much stronger case of the same kind occurred. Mr. Creevey, a member, had made a charge against an individual in the house of commons, and incorrect reports of his speech having appeared in several newspapers, Mr. Creevey sent a correct report to an editor, requesting him to publish it in his newspaper. A jury found Mr. Creevey guilty of libel, and the court of King's Bench refused an application for a new trial; on which occasion Lord Ellenborough said 'a member of that house has spoken what he thought material, and what he was at liberty to speak, in his character as a member of that house. So far he is privileged: but he has not stopped there; but, unauthorised by the house, he has chosen to publish an account of that speech in what he has pleased to call a perverted form, and in that publication has thrown out reflections injurious to the character of an individual.'

Freedom from Arrest.—The Speaker's petition prays on behalf of the commons 'that their persons, *their estates, and servants*, may be free from arrests and all molestations.' These words are not more extensive than the privilege as formerly enjoyed, and instances in which it has been enforced may be found in nearly every page of the earlier volumes of the Journals. This privilege has however been limited by statute, the last of which (10 Geo. III., c. 50) states in the preamble that the previous laws were insufficient to obviate the inconveniences arising from the delay of suits by reason of privilege of parliament, and enacts that 'any person may at any time commence and prosecute any action or suit, &c., against any peer or lord of parliament, or against any of the knights, citizens, or burgesses for the time being, or against any of their menial or any other servants, or any other person entitled to the privilege of parliament, and no such action shall be impeached, stayed, or delayed by or under colour or pretence of any privilege of parliament.' Obedience to any rule of the courts at Westminster may be enforced by distress infinite, in case any person entitled to the benefit of such rule shall choose to proceed in that way.

The persons of members are still free from arrest or imprisonment in civil actions, but their property is as liable to the legal claims of all other persons as that of any private individual. Their servants do not enjoy any privilege or immunity whatever.

The privilege of freedom from arrest has always been subject to the exception of cases of 'treason, felony, and surety of the peace;' and though in other criminal charges each house may, if it see fit, prevent the abstraction of a member from his parliamentary duties, the case of Lord Cochrane, in 1815, will show how little protection the house of commons extends to its members in such cases. Lord Cochrane, having been indicted and convicted for a conspiracy, was committed to the King's Bench prison. He afterwards escaped, and was arrested by the marshal while sitting on the privy councillor's bench in the house of commons, on the right hand of the chair, at which time there was no member present, prayers not having been read. The committee of privileges declared that by this proceeding of the marshal of the King's Bench 'the privileges of parliament did not appear to have been violated so as to call for the interposition of the house.'

Courts of justice have committed privileged persons for contempt, and parliament has refused to protect them. By a standing order of the house of lords, 6th June, 1757, it was declared 'that no peer or lord of parliament hath privilege of peerage or of parliament against being compelled by process of the courts of Westminster hall to pay obedience to a writ of habeas corpus directed to him;' and in the case of Earl Ferrers, it was decided that an attachment may be granted if a peer refuses obedience to the writ of habeas corpus. There have been two recent cases, that of Mr. Long Wellesley in 1831, and that of Mr. Lechmere Charlton in 1837, in which members committed by the lord-chancellor for contempt have laid claims to privilege, which were not admitted by the house of commons.

Peers are always free from arrest; and as regards the commons, their privilege is supposed to exist for 40 days after every prorogation and 40 days before the next appointed meeting.

Jurisdiction of Courts of Law in Matters of Privilege.—In connection with the exercise of privilege, an important point of law arises as to the jurisdiction of courts of justice. It is one of great interest and still greater doubt at the present moment, and has at various times been the occasion of much dispute and difficulty. Each house of parliament is acknowledged to be the judge of its own privileges. Sir Edward Coke affirms, 'whatever matter arises concerning either house of parliament, ought to be examined, discussed, and adjudged in that house to which it relates, and not elsewhere.' (4 *Inst.*) But again, in the disputes in the case of the Aylesbury men, which has been already referred to, the lords communicated to the commons at a conference a resolution, 'that neither house of parliament have power by any vote or declaration to create to themselves new privileges not warranted by the known laws and customs of parliament;' which was assented to by the commons. (14 *Commons' Journals*, 555, 560.) The degree of jurisdiction to be exercised by the courts and the proper mode of dealing with causes involving matters of privilege, it would indeed be difficult to determine, after the inconsistencies which have been shown in practice and the great variety of opinions expressed by learned men. No more than a concise statement of a few cases will be needed to show the difficulties in which the question is involved.

First, as to the right of courts to inquire into the existence and nature of privileges claimed by either house of parliament. Coke lays it down, that 'judges ought not to give any opinion of a matter of parliament, because it is not to be decided by the common laws, but *secundum leges et consuetudinem parliamenti*; and so the judges in divers parliaments have confessed.' (4 *Inst.*, 15.) When Paty, one of the Aylesbury men, was brought before the Queen's Bench on a writ of habeas corpus, Mr. Justice Powell said 'this court may judge of privilege, but not contrary to the judgment of the house of commons;' and again, 'this court judges of privilege only incidentally; for when an action is brought in this court, it must be given one way or other.' (2 Lord Raymond, 1105.) The opinions of other judges to the same effect, expressed at different times, might also be given. The words contained in the Bill of Rights, that the 'debates and *proceedings* in parliament ought not to be impeached or questioned in any court or place out of parliament,' are generally relied upon as confirmation of this doctrine. If this view were always taken of the question, little difference between parliament and the courts of law would arise. The course would be simple. Whatever action might be brought would be determined in a manner agreeable to the house whose privileges were questioned; and if the lords, in case of appeal, were to abide by the same rule, there would be no dissensions. But as such unanimity of opinion has not always existed, there has been a clashing of jurisdictions which nothing probably but a statute can prevent for the future.

A judgment was obtained against Sir W. Williams, the Speaker of the house of commons, in the second year of James II., for having caused a paper entitled 'Dangerfield's Narrative' to be printed by order of the house. This the house declared to be 'an illegal judgment,' and against the freedom of parliament. A bill was also brought in to reverse the judgment, but it miscarried in three different sessions. (10 *Commons' Journals*, 177, 205.)

The denial of the exclusive jurisdiction claimed by the commons in 1704, in respect of the right of elections, as stated above, is another important occasion in which the privilege of the commons has clashed with the judgments of legal tribunals.

The only other case which need be mentioned in this place is that of Stockdale v. Hansard. Messrs. Hansard, the printers of the house of commons, had printed, by order of that house, the Reports of the Inspectors of Prisons, in which a book published by Stockdale was described in a manner which he conceived to be libellous. He brought an action against Messrs. Hansard during a recess, but had a verdict against him upon a plea of justification, as the jury considered the description of the work in question to be accurate. On that occasion Lord Chief Justice Denman, who tried the cause, made a declaration adverse to the privileges of the house, which Messrs. Hansard had set up as part of their defence. In his direction to the jury, his lordship said 'that the fact of the house of commons having directed Messrs. Hansard to publish all their parliamentary reports is no justification for them, or for any bookseller who publishes a parliamentary report containing a libel against any man.' In consequence of these proceedings, a committee was appointed, on the meeting of parliament in 1837, to examine precedents and to ascertain the law and practice of parliament in reference to the publication of papers printed by order of the house. The result of these inquiries was the passing of the following resolutions by the house:—

'That the power of publishing such of its reports, votes, and proceedings as it shall deem necessary or conducive to the public interests is an essential incident to the constitutional functions of parliament, more especially of this house as the representative portion of it.

'That by the law and privilege of parliament, this house has the sole and exclusive jurisdiction to determine upon the existence and extent of its privileges, and that the institution or prosecution of any action, suit, or other proceeding, for the purpose of bringing them into discussion or decision before any court or tribunal elsewhere than in parliament, is a high breach of privilege, and renders all parties concerned therein amenable to its just displeasure, and to the punishment consequent thereon.

'That for any court or tribunal to assume to decide upon matters of privilege inconsistent with the determination of either house of parliament is contrary to the law of parliament, and is a breach and contempt of the privileges of parliament.'

Notwithstanding these resolutions, Stockdale immediately commenced another action. The Queen's Bench decided against the privileges of the house. A third action was then brought by Stockdale, and not being defended, judgment went by default, and the damages were assessed in the sheriff's court.

As yet the jurisdiction of the courts to inquire into the privileges of parliament and to give judgments inconsistent with its determination has alone been touched upon; the next question is as to the mode of dealing with actions involving privilege when brought in the courts. The practice has been extremely various and inconsistent, as a rapid view of it will show. An action had been brought against Topham, the serjeant-at-arms, for executing the orders of the house of commons in arresting certain persons. Topham pleaded *to the jurisdiction of the court*, but his plea was overruled, and judgment was given against him. The house declared the judgment to be a breach of privilege, and committed Sir F. Pemberton and Sir T. Jones, the judges, to the custody of the serjeant. (10 *Commons' Journals*, 227.) In speaking of this proceeding, Lord Ellenborough expressed his surprise 'that a judge should have been questioned for having given a judgment which no other judge who ever sat in his place could have differed from.'

In the case of Ashby and White, so often referred to, the commons declared 'that whoever shall presume to commence any action, and all attorneys, solicitors, counsellors, and serjeants-at-law soliciting, prosecuting, or pleading in any case, are guilty of a high breach of the privileges of this house.' The effect of this resolution, if obeyed, would be to prevent the courts from coming to any decision at all upon matters of privilege, as an action would be stopped at its commencement; but the principle has not been adhered to.

When Sir Francis Burdett brought actions against the Speaker and the serjeant-at-arms, in 1810, for taking him to the Tower in obedience to the orders of the house of commons, they were directed to plead, and the attorney-general received instructions to defend them. A committee at the same time reported a resolution 'that the bringing these actions for acts done in obedience to the orders of the house is a breach of privilege,' but it was not adopted by the house. The actions proceeded in the regular course, and the court of King's Bench sustained and vindicated the authority of the house.

It has been already said that Stockdale's first action was brought when parliament was not sitting. Having no specific directions therefore from the house, Messrs. Hansard pleaded to the action. On the general issue they proved the orders of the house, which were held to be no protection, but had judgment upon a plea which would have availed them equally had they printed the report complained of on their own account. Notwithstanding its resolutions, the house, on being acquainted with this action, instead of acting upon them when a second was commenced, reverted to the precedent of 1810, and directed Messrs. Hansard to plead, and the attorney-general to defend them. In this case nothing but the privileges of the house of commons were relied upon in defence of Messrs. Hansard, and the court of Queen's Bench unanimously decided against them. Still the house of commons was reluctant to act upon its own resolutions, and instead of punishing the plaintiff and his legal advisers, 'under the special circumstances of the case,' it ordered the damages and costs to be paid. The resolutions however were not rescinded, and it was then determined that in case of future actions, Messrs. Hansard should not plead at all; and that the parties should suffer for their contempt of the resolutions and authority of the house. Another action was brought by the same person and for the same publication. Messrs. Hansard did not plead, the judgment went against them by default, and the damages were assessed by a jury in the sheriff's court at 600*l*. The sheriffs of Middlesex levied for that amount, but having been served with copies of the resolutions of the house, they were anxious not to pay the money to Stockdale until they were unable to delay the payment any longer. At the opening of the session of parliament in 1840, the money was still in their hands. The House of Commons at once entered on the consideration of these proceedings, which had been carried on in spite of its resolutions, and in the first place committed Stockdale to the custody of the serjeant-at-arms. The sheriffs were desired to refund the money, and, on their refusal, were also committed. Mr. Howard, the solicitor of Mr. Stockdale, was suffered to escape with a reprimand. The sheriffs retained possession of the money until an attachment was issued from the Queen's Bench, when they paid it over to Stockdale. Stockdale, while in prison, commenced a fourth action by the same solicitor, and with him was committed to Newgate for the offence; and Messrs. Hansard were again ordered not to plead. Once more judgment was entered up against them, and a writ of inquiry of damages issued.

Mr. France, the under-sheriff, upon whom the execution of this writ devolved, having been served with the resolutions of the commons, expressed by petition his anxiety to pay obedience to them, and sought the protection of the house. He then obtained leave to show cause before the court of Queen's Bench on the fourth day of Eastern term why the writ of inquiry should not be executed. Meanwhile the imprisonment of the plaintiff and his attorney did not prevent the prosecution of further actions. Mr Howard's son, and his clerk, Mr. Pearce, having been concerned in conducting such actions, were committed for the contempt, and Messrs. Hansard, as before, were instructed not to plead. At length as there appeared to be no probability of these vexatious actions being discontinued, a bill was introduced into the commons, by which proceedings, criminal or civil, against persons for publication of papers printed by order of either house of parliament, are to be stayed by the courts, upon delivery of a certificate and affidavit to the effect that such publication is by order of parliament. This bill passed the commons, and was sent up to the lords, by whom it was returned with certain amendments, to which the commons agreed. In executing the Speaker's warrant for taking Mr. Howard into custody, the messengers had remained some time in his house, for which he brought an action of trespass against them. As it was possible that they might have exceeded their authority, and as the right of the house to commit was not directly brought into question, the defendants were, in this case, instructed to plead; although a clause for staying further proceedings in the action was contained in the bill which was pending, at that time, in the house of lords; by whom however it was afterwards omitted.

FORMS OF PROCEDURE.

Meeting of Parliament: Preliminary Proceedings.—On the meeting of a new parliament it is the practice for the lord chancellor, with other peers appointed by commission under the great seal for that purpose, to open the parliament by stating 'that her Majesty will, as soon as the members of both houses shall be sworn, declare the causes of her calling this parliament; and it being necessary a Speaker of the house of commons should be first chosen that you, gentlemen of the house of commons, repair to the place where you are to sit, and there proceed to the appointment of some proper person to be your Speaker; and that you present such person whom you shall so choose here, to-morrow (at an hour stated) for her Majesty's royal approbation.' The commons then proceed at once to the election of their Speaker. If any debate arises, the clerk at the table acts as Speaker, and standing up, points to the members as they rise. He also puts the question. When the Speaker is chosen, his proposer and seconder conduct him to the chair, where, standing on the upper step, he thanks the house and takes his seat. It is usual for some members to congratulate him when he has taken the chair. As yet he is only Speaker elect, and as such presents himself on the following day, in the house of lords, and acquaints the lords commissioners that the choice of the commons has 'fallen upon him,' that he feels the difficulties of his high and arduous office, and that, 'if it should be her Majesty's pleasure to disapprove of this choice, her majesty's faithful commons will at once select some other member of the house better qualified to fill the station than himself.' It is stated by Hatsell, that there have been only two instances 'in which neither this form, of having the royal permission to proceed to the election of a Speaker, nor the other, of the king's approbation of the person elected, have been obser

The first is the election of Sir Harbottle Grimstone, on the 25th of April, 1660, to be Speaker of the Convention Parliament which met at the Restoration; the other, is the election of Mr Powle, 22nd January, 1688-9, in the Convention Parliament at the Revolution.' The only instance of the royal approbation being refused is in the case of Sir Edward Seymour in 1678. Sir John Topham indeed was elected Speaker in 1450, but his excuse was admitted by the king, and another was chosen by the commons in his place. In order to avoid a similar proceeding on the part of the king, Sir Edward Seymour, who knew that it had been determined to accept his excuse, omitted the usual form.

When the Speaker has been approved, he lays claim on behalf of the commons, 'by humble petition, to all their ancient and undoubted rights and privileges,' which being confirmed, the Speaker with the commons retires from the bar of the house of lords.

Both houses then proceed to take the oaths required by law. In the commons the Speaker takes them before any other member. Three or four days are usually occupied in this duty before the queen declares to both houses, in person or by commission, the causes of calling the parliament. From this time business proceeds regularly. The first thing usually done in both houses is to vote an address in answer to the speech from the throne.

Before any business is undertaken, prayers are read; in the house of lords by a bishop, and in the commons by their chaplain. The former usually meet at five o'clock in the afternoon, the latter at four.

Conduct of Business, Divisions, &c.—In the house of lords business may proceed when three peers are present, but forty members are required to assist in the deliberations of the lower house. If that number be not present at four o'clock in the afternoon, or if notice be taken, or if it appear on a division, that less than that number are present, the Speaker adjourns the house until the next sitting day. In both houses all questions are decided by a majority, but in the lords proxies are counted, while in the commons none may vote but those present in the house when the question is put by the Speaker or chairman. When any question arises upon which a difference of opinion is expressed, it becomes necessary to ascertain the numbers on each side. In the lords, the party in favour of the question are called 'content,' and that opposed to it, 'not-content.' In the commons these parties are described as the 'ayes' and 'noes.' When the Speaker cannot decide by the voices which party has the majority, or when his decision is disputed, a division takes place. This is effected in the lords by sending the 'contents' or 'non-contents,' as the case may be, to the other side of the bar, and leaving one party in the house. Each party is thus counted separately. The practice in the other house, until 1836, was to send one party forth into the lobby, the other remaining in the house. Two tellers for each party then counted the numbers, and reported them. In 1836 it was thought advisable to adopt some mode of recording the names of members who voted, and for this purpose several contrivances were proposed. The one adopted and now in operation is this. There are two lobbies, one at each end of the house; on a division the house is entirely cleared, one party being sent to each of the lobbies. Two clerks are stationed at each of the entrances to the house, holding lists of the members in alphabetical order printed upon large sheets of thick pasteboard so as to avoid the trouble and delay of turning over pages. While the members are passing into the house again, the clerks place a mark against each of their names, and the tellers count the number. These sheets of pasteboard are sent off to the printer, who prints the marked names in their order; and the division lists are then delivered on the following morning together with the votes and proceedings of the house. This plan has been quite successful: the names are taken down with great accuracy, and very little delay is occasioned by the process.

In committees of the whole house, divisions are taken by the members of each party crossing over to the opposite side of the house, unless five members require that the division shall be taken in the usual manner.

In addition to the power of expressing assent or dissent by a vote, peers may record their opinion and the grounds of it by a 'protest,' which is entered in the Journals, together with the names of all the peers who concur in it.

When matters of great interest are to be debated in the upper house, the lords are 'summoned;' and in the house of commons an order is occasionally made that the house be called over, and members not attending when their names are called, are reported as defaulters, and ordered to attend on another day, when, if they are still absent and no excuse be offered, they are sometimes committed to the custody of the serjeant-at-arms.

The business which occupies nearly the whole attention of both houses (if we except the hearing of appeals by the lords and the trial of controverted elections by the commons) is the passing of bills; and the mode of proceeding with respect to them may be briefly described in the first place.

Bills, Public and Private.

Bills are divided into two classes—such as are of a public nature affecting the general interests of the state, and such as relate only to local or private matters. The former are introduced directly by the motions of members; the latter are brought in upon petitions from the parties interested, after the necessary notices have been given and all forms required by the standing orders have been complied with.

With few exceptions, public bills may originate in either house, unless they be for granting supplies of any kind, or involve directly or indirectly the levying or appropriation of any tax or fine upon the people. The exclusive right of the commons to deal with all legislation of this nature affects very extensively the practice of introducing private bills into either house. Thus, all those which authorise the levying of local tolls or rates are brought in upon petition to the lower house. These compose by far the greater part of all private bills. All measures of local improvement, whether for enclosing lands, lighting, watching, and improving towns, establishing police, or making roads, bridges, railways, canals, or other public works, originate in the commons. On the other hand, many bills of a personal nature are always sent down from the lords, such as bills affecting private estates, for dissolving marriages, and for the naturalization of aliens. As a question of principle it is perhaps unavoidable that so large a proportion of bills must begin in one house, but much obstruction to business and a very unequal division of labour are the results of the practice. Bills affecting the peerage must originate in the lords, and acts of grace with the crown, where the prerogative of mercy is vested.

Progress of Bills: Public Bills.—Motions for leave to bring in bills of a public nature are not very frequently refused. The more usual time for opposing any measure in its progress is on the second reading, when all the provisions are known, and the general principle and effect of them may be considered. When leave is given to bring in a bill, certain members are ordered to prepare it, being the proposer and seconder of the motion, to whom others are sometimes added. It is then brought in and read a first time, and a day is fixed for the second reading, which generally leaves a sufficient interval for the printing and circulation of the bill.

It has been already said that the second reading is the occasion on which a bill is more particularly canvassed. Its principle is at that time made the subject of discussion, and if it meet with approval, the bill is committed, either to a committee of the whole house or to a select committee, to consider its several provisions in detail. A committee of the whole house is in fact the house itself, in the absence of the Speaker from the chair; but the rule which allows members to speak as often as they think fit, instead of restricting them to a single speech, as at other times, affords great facilities for the careful examination and full discussion of details. The practice of referring bills of an intricate and technical description to select committees has become very prevalent of late years, and might be extended with advantage. Many bills are understood by a few members only, whose observations are listened to with impatience, and thus valuable suggestions are often withheld in the house, which in a committee might be embodied in the bill. By leaving such bills to a select committee, the house is enabled to attend to measures more generally interesting, while other business, of perhaps equal importance, is proceeding at the same time; and it has always the opportunity of revising amendments introduced by the committee.

Before a bill goes into committee there are certain blanks for dates, amount of penalties, &c., which are filled up in this stage. Bills of importance are often recommitted, or in other words, pass twice, and even in some instances three or four times through the committee. When the proceedings in committee are terminated, the bill is reported with the amendments to the house, on which occasion they are agreed to, amended, or disagreed to, as the case may be. If many amendments have been made, it is a common and very useful practice to reprint the bill before the report is taken into consideration. After the report has been agreed to, the bill with the amendments is ordered to be engrossed previous to the third reading. A proposition was made not long since, but without success, for discontinuing the custom of engrossment upon parchment, and for using an examined copy of the printed bill, signed by the clerk of the house, for all the purposes for which the engrossed copy is now required.

The third reading is a stage of great importance, on which the entire measure is reviewed, and the house determines whether, after the amendments that have been made on previous stages, it is fit on the whole to pass and become law. The question, 'that this bill do pass,' which immediately succeeds the third reading, is usually no more than a form, but there have been occasions on which that question has been opposed, and even negatived. The title of the bill is settled last of all.

An interval of some days usually elapses between each of the principal stages of a bill; but when there is any particular cause for haste, and there is no opposition, these delays are dispensed with, and the bill is allowed to pass through several stages, and occasionally through all, on the same day.

This statement of the progress of bills applies equally to both houses of parliament. There is however a slight distinction in the title of a bill while pending in the lords, which is always 'intituled an act,' whether it has originated in the lords or has been brought up from the commons.

When the commons have passed a bill, they send it to the lords by one of their own members, who is usually accompanied by others. The lords send down bills by two masters in chancery; unless they relate to the crown or the royal family, in which case they are generally sent by two judges.

Private Bills.—In deliberating upon private bills parliament may be considered as acting judicially. The conflicting interests of private parties, the rights of individuals, and the protection of the public have to be reconciled. Care must be taken, in furthering an apparently useful object, that injustice be not done to individuals, although the public may derive advantage from it. Vigilance and caution should be exercised lest parties professing to have the public interests in view should be establishing, under the protection of a statute, an injurious monopoly. The rights of landowners amongst themselves, and of the poor, must be scrutinised in passing an enclosure bill. Every description of interest is affected by the making of a railway. Land, houses, parks, and pleasure-grounds are sacrificed to the superior claim of public utility over private rights. The repugnance of some proprietors to permit the line to approach their estates—the eagerness of others to share in the bounty of the company and to receive treble the value of their land, embarrass the decision of parliament as to the real merits of the undertaking, which would be sufficiently difficult without such contentions. If a company receive authority to disturb the rights of persons not interested in their works, it is indispensable that ample security be taken that they are able to complete them so as to attain that public utility which alone justified the powers being entrusted to them. The imprudence of speculators is to be restrained, and unprofitable adventures discountenanced, or directed into channels of usefulness and profit. In short, parliament must be the umpire between all parties, and endeavour to reconcile all interests.

The inquiries that are necessary to be conducted in order to determine upon the merits of private bills are too extensive for the house to undertake, and it has therefore been usual to delegate them to committees. To prevent parties from being taken by surprise, the standing orders require certain notices to be given (to the public by advertisement, and to parties interested by personal service) of the intention to petition parliament. The first thing which is done by the commons on receiving the petition therefore is to inquire whether these notices have been properly given, and if all other forms prescribed by the standing orders have been observed. This inquiry is confided to a committee, who report their determination to the house. It will be necessary here to explain the constitution of this committee. Until very recently it was the practice for the Speaker to prepare 'lists' of members who were to form committees on bills relating to particular counties, in such a manner as to combine a fair proportion of members connected with the locality, with the representatives of places removed from any local influence or prejudice. Each of these lists consisted of upwards of a hundred members, any five of whom formed the committee. This system was liable to many objections. The number of the committee was too great to allow any responsibility to attach to the members. They were canvassed to vote by each of the opposing parties without having heard the evidence or arguments on either side; and were sometimes induced to crowd into the committee-room and reverse decisions which had been arrived at after long and patient inquiry. These evils led to an experiment which has not long been tried, but which is undoubtedly an improvement upon the former system. All petitions for private bills are referred to the same select committee which is appointed at the beginning of each session, and is composed of members whose habits of business and practical acquaintance with this branch of legislation constitute them a tribunal in every respect superior to the old list committees. A uniform construction of the standing orders is more likely to be maintained by one committee than by several; and partiality in any one case is scarcely conceivable in a body which has to decide upon all.

The report which this committee makes to the house is simply whether the standing orders have been complied with or not. If it be favourable, leave is at once given to bring in the bill; if not, it is referred to another committee also appointed at the beginning of the session, and called the 'committee on standing orders,' whose province it is to inquire into the circumstances of the case, and report their opinion as to the propriety of dispensing with the standing orders, of requiring notices, or imposing new conditions. If this committee decide that the parties are not entitled to indulgence, it is still competent for the house to relax its standing orders, as it does not by any means delegate its authority; yet in practice the report is final. Attempts are sometimes made to overrule it, but never, we believe, with success.

When nothing has occurred to obstruct the progress of the bill, it is read a first time; after which seven clear days must elapse before the second reading, the bill being printed and delivered to members in the interval. The principle is now considered by the house, as in the case of public bills, and if the question for reading the bill be carried, it is then committed to a select committee. The constitution of committees on petitions has already been explained. While the list committees were resorted to, both the petition and the bill itself were referred to the same committee, but at present a new mode of appointing committees is in operation. It has been tried for a short time only, and must be tested by further experience before any decided opinion can be given upon its merits. The lists which have already been described are much reduced in number, and a committee of selection is appointed, to whom members upon the list must signify their intention to attend throughout the whole proceedings before they are permitted to vote. The committee of selection have power also to add to the Speaker's list any member who declares that his constituents are locally interested in the bill, provided they be satisfied as to the reality of such interest. They then add a certain number of other members not locally interested, in such a proportion as they may think fit.

In committee, the bill, if opposed, undergoes a severe examination. Petitions against it are presented to the house and referred to the committee, who hear counsel and examine witnesses. The principle of the bill has been by no means established by the second reading, for the preamble is discussed in the committee, and if it be determined by them that it has not been proved, there is an end of the bill. The report is ordered to lie upon the table, and generally no further notice is taken of it. The house indeed seems to delegate its authority more entirely to the committee on a bill than to any other committee, as it allows them to decide against a principle in favour of which it has already declared an opinion: however it has sometimes interfered in a manner which will be best explained by briefly detailing the cases. In 1836 the committee on the Durham (South-West) Railway Bill reported, according to the usual form, that the preamble had not been proved to their satisfaction; upon which they were ordered to re-assemble for the purpose of reporting specially the preamble, and the evidence with reasons in detail on which they had come to their conclusions. The detailed report was accordingly made, but the decision of the committee was still further questioned. In 1837 the bills for making four distinct lines of railway to Brighton had been referred to one committee. An unprecedented contest arose between the promoters of the competing lines; and at length it was apprehended that all the bills would be lost by the combination of three of the parties against each of the lines on which the committee would have to determine separately. This consequence was prevented by an instruction to the committee to 'make a special report of the engineering particulars of each of the lines, to enable the house to determine which to send back for the purpose of having the landowners heard and the clauses settled.'

If the committee allow that the allegations of the preamble have been proved, they proceed to consider the bill clause by clause. But before we quit the subject of the preamble, the modern practice concerning railway bills may be adverted to. There are so many grounds upon which the preamble may fail to be proved, and so many points on which the committee should be informed before a just decision can be given, that in 1836 a rule was established which obliges the committee to report in detail. On receiving the report, the house is now acquainted with the chief particulars from which the expediency of the measure may be collected. The length of the line,—the probable expenses of the works, and the sufficiency of the estimates,—the revenue expected from passengers and from agricultural produce or merchandise, with the grounds of the calculation,—the engineering difficulties—the gradients and curves, are all distinctly stated. This system might be extended, with great advantage, to other classes of bills; but is confined at present to railway bills alone. Much attention has been paid of late to the improvement of the modes of conducting private business, and it is not improbable that detailed reports may form part of the future recommendations of committees, on whom the task of suggesting further improvements may be imposed.

By a standing order, 14th December, 1837, parties complaining of any vote of a committee on a private bill are at liberty to petition against that particular vote, on entering into a bond with two sureties for payment of costs. A committee of seven may then be appointed, by ballot, out of their members who are chosen at the beginning of the session as 'the committee of appeal.' This power of objecting to the votes of a committee however is very rarely resorted to, and appears to be little more than nominal. There have been shown by the house some reluctance to permit any effectual appeal, and a desire to limit the application of the standing order.

It has been said that public bills are occasionally referred to select committees; these however must also pass through a committee of the whole house. Private bills are committed to select committees only. Bills for divorce, by a standing order, were committed, like public bills, to committees of the whole house, until the 12th February, 1840, when an order was made for referring them to a select committee of nine members.

It will not be necessary to pursue any further the progress of private bills, which differs only from that already described in respect of bills of a public nature, in the necessity for certain specified intervals between each stage, and for notices in the private bill office.

In the house of lords, when a private bill is unopposed, it is committed to the permanent chairman of committees, and any other peers may attend; but when a bill is to be opposed, the committee on standing orders inquires whether the standing orders have been complied with, and if so, the bill is referred to a committee of five appointed by a standing committee of five peers, to whom is confided the duty of selecting all committees on opposed bills, according to the circumstances of each case.

In order to ensure a proper acquaintance with the provisions of private bills, some of which are very voluminous, the house of commons have lately adopted a rule requiring copies of the bills to be laid before them six days before the second reading, and copies of the amendments made by the committee, before the house take the report into consideration.

Conferences between the two Houses.—The progress of bills in each house of parliament having been detailed, it only remains to describe the subsequent proceedings in case of difference between them. When a bill has been returned by either house to the other, with amendments which are disagreed to, a conference is desired by the house which disagrees to the amendment, to acquaint the other with the reasons for such disagreement; in order, to use the words of Hatsell, 'that after considering those reasons, the house may be induced, either not to insist upon their amendments, or may, in their turn, assign such arguments for having made them, as may prevail upon the other house to agree to them. If the house which amend the bill are not satisfied and convinced by the reasons urged for disagreeing to the amendments, but persevere in insisting upon their amendments, the form is to desire another conference; at which, in their turn, they state their arguments in favour of the amendments, and the reasons why they cannot depart from them; and if after such second conference the other house resolve to insist upon disagreeing to the amendments, they ought then to demand a "free conference," at which the arguments on both sides may be more amply and freely discussed. If this measure should prove ineffectual, and if, after several free conferences, neither house can be induced to depart from the point they originally insisted upon, nothing further can be done, and the bill must be lost.' An interesting occasion on which all these proceedings were successively adopted has recently occurred; a free conference had not been held since 1740, until a contest arose in 1836 upon amendments made by the lords to a bill for amending the Act for regulating Municipal Corporations.

Whether the conference be desired by the lords or by the commons, the former have the sole right of appointing the time and place of meeting. The house that seeks the conference must clearly express in their message the subject upon which it is desired, and it is not granted as a matter of course. There are many instances to be found in the Journals in which a conference has been refused, but not of late years. The reasons that are to be offered to the other house are prepared by a committee appointed for that purpose, who report them for the approval of the house. These reasons are generally very short, but in some cases arguments have been entered into at considerable length. The conference is conducted by 'Managers' for both houses, who, on the part of the house desiring the conference, are the members of the committee who have drawn up the reasons, to whom others are occasionally added. Their duty is to read and deliver the reasons with which they are entrusted to the managers of the other house, who report them to the house which they represent. At a free conference the managers on either side have more discretion vested in them, and may urge whatever arguments they think fit. A debate arose in the last free conference, to which we have just alluded, and the speeches of the managers were taken in short-hand and printed. While the conference is being held, the business of both houses is suspended until the return of the managers.

Amendments made to bills by either house are not the only occasions upon which conferences are demanded. Resolutions of importance, in which the concurrence of the other house is desired, are communicated in this manner. Reports of committees have also been communicated by means of a conference. In 1829 a conference was demanded by the commons to request an explanation of the circumstances under which a bill that had been amended by the lords had received the royal assent without being returned to the commons for their concurrence. The lords expressed their regret at the mistake, and stated that they had themselves been prepared to desire a conference upon the subject, when they received the message from the commons.

Conferences were formerly held in the Painted Chamber, but since the destruction of the houses of parliament by fire in 1834, that apartment has been appropriated to the sittings of the house of peers, and conferences now meet in one of the lords' committee rooms.

Royal Assent to Bills.—When a bill has passed both houses, it remains in the house of lords until the royal assent is given, unless it be a bill of supply, in which case it is returned to the commons. The royal assent may be signified by the king either in person or by commission. Several bills are usually allowed to accumulate before the royal assent is given, and then, if it be during a session, a commission is generally issued under the great seal for that purpose. Three of the lords commissioners, seated on a form between the throne and the woolsack in the house of lords, command their usher of the black rod to signify to the commons that their attendance is desired, upon which the commons with the Speaker come to the bar. The titles of the bills being then read, the royal assent to each is signified by the clerk of the parliament in Norman French. For a public bill the form of expression is '*Le roy le veult;*' for a private bill, '*Soit fait come il est desiree;*' upon a petition demanding a right, whether public or private, '*Soit droit fait come il est desiree.*' [PETITION OF RIGHT.] A bill of supply is carried up and presented by the Speaker, and the assent is pronounced in the words '*Le roy remercie ses bons subjects, accepte leur benevolence, et ainsi le veult.*' In an act of grace which has the royal assent before it is agreed to by the two houses, the clerk says, '*Les prelats, seigniors, et commons en ce present parliament assemblees, au nom de touts vos autres subjects remercient tres humblement vostre majestee et prient a Dieu vous doner en santé bone vie et longue.*' The form of words used to express a denial of the royal assent was '*Le roy s'avisera.*' The last occasion in which this power was exercised was in 1707, when Queen Anne refused her assent to a bill for settling the militia in Scotland.

The royal assent is rarely given in person, except at the close of a session, when the king attends to prorogue the parliament, and then he signifies his assent to such bills as may have passed since the last commission was issued: but bills for making provision for the honour and dignity of the crown, such as the bills for settling the Civil Lists, have generally been assented to by the king in person immediately after they have passed both houses.

During the Commonwealth the lord protector consented to bills in English, but on the Restoration the old form of words was reverted to, and only one attempt has been made to abolish it. In 1706 the lords passed a bill 'for abolishing the use of the French tongue in all proceedings in Parliament and courts of justice.' This bill dropped in the house of commons. An act passed in 1731, for conducting all proceedings in courts of justice in English, but no alteration was made in the old forms still in use in parliament.

Committees.—Committees are either 'of the whole house' or 'select.' The former are in fact the house itself, with a chairman instead of the lord chancellor or Speaker presiding. There is a more free and unlimited power of debate when the house is in committee, as members may speak any number of times upon the same question, from which they are restrained on other occasions. Select committees are specially appointed, generally for inquiring into particular subjects connected with legislation. It is usual to give them the 'power to send for persons, papers, and records;' but in case of any disobedience to their orders, they have no direct means of enforcing compliance, but must report the circumstances to the house, which will immediately interfere.

In case of an equality of voices, the chairman, who is chosen by the committee out of its own members, gives the casting vote. Some misconception appears to have existed as to the precise nature of the chairman's right of voting. In 1836, the house of commons was informed that the chairman of a select committee had first claimed the privilege to vote as a member of the committee, and afterwards, when the voices were equal, of giving a casting vote as chairman, and that such practice had of late years prevailed in some select committees; when it was declared by the house that, according to the established rules of parliament, the chairman of a select committee can only vote when there is an equality of voices. (91 *Commons' Journals*, p. 214.) This error was very probably occasioned by the practice of election committees, which was however confined to them, and only existed under the provisions of acts of parliament.

In 1837, some regulations were made by the house of commons for rendering select committees more efficient and responsible. The number of members on a committee was limited to fifteen. Lists of their names are to be affixed in some conspicuous place in the committee-clerk's office and the lobby. Members moving for the committee are to ascertain whether the gentlemen they propose to name will attend. To every question asked of a witness, the name of the member who asks it is prefixed in the minutes of evidence laid before the house; and the names of the members present at each sitting, and, in the event of any division, the question proposed, the name of the proposer, and the votes of each member, are entered on the minutes and reported to the house. [COMMITTEES.]

It is not intended to touch upon the elective franchise, or upon the proceedings at elections; but the mode of trying election petitions will require a notice in this place.

Trial of Election Petitions.—Before the year 1770, controverted elections were tried and determined by the whole house of commons, as mere party questions, upon which the strength of contending factions might be tested. In 1741, Sir Robert Walpole, after repeated attacks upon his government, was at last driven from office by a vote upon the Chippenham election petition. 'Instead of trusting to the merits of their respective causes,' said Mr. Grenville, in proposing the measure which has since borne his name, 'the principal dependence of both parties is their private interest among us, and it is scandalously notorious that we are as earnestly canvassed to attend in favour of the opposite sides, as if we were wholly self-elective and not bound to act by the principles of justice, but by the discretionary impulse of our own inclinations; nay, it is well known that in every contested election, many members of this house, who are ultimately to judge in a kind of judicial capacity between the competitors, enlist themselves as parties in the contention, and take upon themselves the partial management of the very business upon which they should determine with the strictest impartiality.' The principle of the Grenville Act, and of others which were passed at different times since 1770, was to select committees for the trial of election petitions by lot. By the last of these (9 Geo. IV., cap. 22), thirty-three names were balloted from the members present at the time, and each of the parties to the election was entitled to strike off eleven names, and thus reduce the number of the committee to eleven. Whatever party attended on the day appointed for a ballot in the greatest force, was likely to have a preponderance in the committee; and the expedient of chance did not therefore operate as a sufficient check to party spirit in the appointment of election committees. Partiality or incompetence was very generally complained of in the decisions of committees appointed in this manner, and in 1839 an act passed establishing a new system,—upon different principles,—increasing the responsibility of individual members, and leaving scarcely anything to the operation of chance.

The following is an outline of the present mode of selecting members for the trial of election petitions. At the beginning of a session the Speaker appoints a general committee of six members, to any or all of whom the house may object, in which case the Speaker is bound to appoint others. If by irreconcileable disagreement of opinion, or by the continued absence of more than two members, the committee, when appointed, should be unable to proceed in the discharge of its duties, or if the house should determine that it shall be dissolved, its functions are to cease. To this general committee all election petitions are referred. The names of all the members of the house are put into an alphabetical list and called over, when certain excuses are allowed to be made; but all who do not then excuse themselves from serving are bound to act as members of election committees when hereafter chosen.* This list is taken by the general committee, from which are selected six, eight, ten, or twelve members, who, on signifying their willingness to serve, are formed into 'the chairman's panel.' The list is then divided into five panels by the general committee, exclusive of the chairman, the order of which is decided by lot, and a number attached to each in the order in which it is drawn. These panels are to be corrected from time to time by the general committee, according to circumstances. The general committee gives three weeks' notice to the parties before it proceeds to appoint a committee for the trial of an election petition. At the expiration of that time it chooses, from the panel standing first in order of service, six members, whose names are read to the parties, who have power to object to any of them on grounds of disqualification specified in the act. When the six members are finally chosen, the chairman's panel appoint one of their own body to act as chairman, who is added accordingly by the general committee. The committee, when thus completed, is sworn, and proceeds to business. If it be reduced to less than six by the non-attendance of members, except it has already sat fourteen days or more, it is dissolved. It may sit with four members only, if it has met for twenty-five days, and with any number, without reference to the time during which it has met, provided all the parties give their consent. All questions are decided by a majority, and in case of an equality of voices, the chairman gives a second or casting vote.

As witnesses giving false evidence before an election committed, or guilty of perjury, it is usual for the house, when acquainted with such misconduct, to instruct the attorney-general to prosecute the parties. The same course has also been pursued with respect to persons proved to have been concerned in bribery.

The determinations of election committees are final, and are immediately carried into effect by the house. If an election be declared void, a new writ is issued; if it be decided that a member has not been duly elected and that another candidate should have been returned, the deputy clerk of the crown is ordered to attend and amend the return, after which the new member is sworn, and takes his seat; and if a petition or the opposition to it be held by the committee to have been frivolous or vexatious, the petitioner or sitting member, as the case may be, is liable to the payment of all the costs.

The last proceeding in parliament which we shall describe is that of

Impeachment.—Impeachment by the commons is a proceeding of great importance, involving the exercise of the highest judicial powers by parliament, and though in modern times it has rarely been resorted to, in former periods of our history it was of frequent occurrence. The earliest instance of impeachment by the commons at the bar of the house of lords was in the reign of Edward III. (1376). Before that time the lords appear to have tried both peers and commoners for great public offences, but not upon complaints addressed to them by the commons. During the next four reigns, cases of regular impeachment were frequent, but no instances occurred in the reigns of Edward IV., Henry VII., Henry VIII., Edward VI., Queen Mary, or Queen Elizabeth. The institution 'had fallen into disuse,' says Mr. Hallam, 'partly from the loss of that control which the commons had obtained under Richard II. and the Lancastrian kings, and partly from the preference the Tudor princes had given to bills of attainder or of pains and penalties, when they wished to turn the arm of parliament against an obnoxious subject.' Prosecutions also in the Star-chamber during that time were perpetually resorted to by the crown for the punishment of state offenders. In the reign of James I., the practice of impeachment was revived, and was used with great energy by the commons, both as an instrument of popular power and for the furtherance of public justice. Between the year 1620, when Sir Giles Mompesson and Lord Bacon were impeached, and the Revolution in 1688, there were about 40 cases of impeachment. In the reigns of William III., Anne, and George I. there were 15, and in George II. only one (that of Lord Lovat, in 1746, for high treason). The last memorable cases are those of Warren Hastings, in 1788, and Lord Melville, in 1805.

An outline of the forms observed in the conduct of impeachments may be briefly given. A member of the house of commons charges the accused of certain high crimes and misdemeanors, and moves that he be impeached. If the house agree to it, the member is ordered to go to the lords, and at their bar, in the name of the house of commons and of all the commons of the United Kingdom, to impeach the accused. A committee is then ordered to draw up articles of impeachment, which are reported to the house, and having been discussed and agreed upon, are engrossed and delivered to the lords. Further articles may be delivered from time to time. In the case of Warren Hastings the articles had been prepared before his impeachment at the bar of the house of lords. The accused sends answers to each article, which are communicated to the commons by the lords; to these, replications are returned if necessary. After these preliminaries the lords appoint a day for the trial. The commons desire the lords to summon the witnesses required to prove their charges, and appoint managers to conduct the proceedings. Westminster Hall has been usually fitted up as the court, which is presided over by the lord high steward. The commons attend with the managers as a committee of the whole house. The accused remains in the custody of the usher of the black rod, to whom he is delivered, if a commoner, by the serjeant-at-arms attending the house of commons. The managers should confine themselves to charges contained in the articles of impeachment. Mr. Warren Hastings complained of matters having been introduced which had not been originally laid to his charge, and the house resolved that certain words ought not to have been spoken by Mr. Burke. Persons impeached of high treason are entitled, by statute 20 Geo. II., c. 30, to make their full defence by counsel, a privilege which is not denied to persons charged with high crimes and misdemeanors.

When the managers have made their charges and adduced evidence in support of them, the accused answers them, and the managers have a right to reply. The lords then proceed to judgment in this manner:—The lord high steward puts to each peer, beginning with the junior baron, the question upon the first article, whether the accused be guilty of the crimes charged therein. The peers in succession rise in their places when the question is put, and standing uncovered, and laying their right hands upon their breast, answer 'guilty,' or 'not guilty,' as the case may be, 'upon my honour.' Each article is proceeded with separately in the same manner, the lord high steward giving his own opinion the last. The numbers are then cast up, and being ascertained, are declared by the lord high steward to the lords, and the accused is acquainted with the result.

(Coke's *Fourth Institute*, cap. 1; *The Sovereigne Power of Parliaments*, by W. Prynne, 1643; *Parliamentary Writs*, by W. Prynne, in four parts, 1659-1664; *Privileges of the Baronage of England when they sit in Parliament*, by John Selden, 12mo., 1642; *Modus tenendi Parliamentum*, by W. PARLIAMENT OF IRELAND. In Ireland, as in England, from the conquest of the country by Henry II. in the latter part of the twelfth century, meetings of the barons were occasionally summoned to consult on public affairs, to which the old historians sometimes give the name of parliaments. But parliaments, in the modern sense, cannot be traced back in Ireland farther than to the latter end of the thirteenth century, or to a date about thirty years subsequent to that of the earliest parliament which is ascertained to have consisted both of lords and commons in England. Simon de Montfort's celebrated parliament, the first for which writs are extant summoning representatives of the counties and boroughs, met at Westminster in 1265 [HENRY III., vol. xii., p. 124]; and the first Irish parliament to which, as far as is known, the sheriffs were directed to return two representatives for each county was held in 1295. Representatives of boroughs in Ireland cannot be traced much higher than to the middle of the fourteenth century. They first make their appearance in 1341, and in an act or ordinance of 1359 they are spoken of as forming an essential part of the parliament.

At this time however and down to a much lower date it was only the small portion of Ireland occupied by the English settlers that was represented in the legislature. Even in the reign of Edward III. only the province of Munster and a part of Leinster were considered as shire land; they were divided into twelve counties. But in the course of the fifteenth century much the greater part of these districts had become to all intents and purposes independent of the English crown; and in the reign of Henry VII. the English dominion and the parliamentary representation were alike confined to the counties composing what was called the Pale, that is, to those of Dublin, Louth, Kildare, and Meath (then comprehending both East and West Meath), with a very few seaports beyond these limits. The vigorous measures taken under Henry VIII. and succeeding kings however gradually extended the authority of the English institutions and laws. The possessors of some of the surginal Irish peerages, after maintaining for centuries an independence as complete as that of the native chieftains themselves, were induced to give their attendance in the house of lords, and many new peerages were conferred, some on Englishmen or persons of English descent, some on the heads of the old Irish families. The twelve antient counties were all reclaimed in the reign of Henry VIII., and others were added by Mary, Elizabeth, and James, till, in the time of the last-mentioned king, the whole island was divided into thirty-two counties, as at present, each returning two representatives. Of these thirty-two counties however it is said there were seventeen in which there was not a single parliamentary borough, while in the remaining fifteen there were only about thirty. But either this account must be wrong or the common statement that James added only forty new boroughs must be an under statement, if, as appears, the entire number of the Irish commons in 1613 was 232. In this number however would be included the two representatives of Trinity College, Dublin. Subsequent new charters to boroughs augmented the house by the year 1692 to 300, at which number it remained stationary. In 1634 the number of peers was 122, and more than 500 Irish peerages were created between that date and the Union. Of course however some also became extinct.

It was only for a very short period of its existence that the Irish parliament was held to be a supreme legislature. Ireland being regarded as a conquered dependency, it was maintained that its parliament was in all respects subordinate to that of England, and subsequently to that of Great Britain, which might make laws to bind the people of the one country as well as of the other. The received legal doctrine used to be, that King John, in the twelfth year of his reign (A.D. 1210), ordained by letters-patent, in right of the dominion of conquest, that Ireland should be governed by the laws of England; in consequence of which both the common law of England and all English statutes enacted prior to that date were held to be of the same authority in Ireland as in England. With regard to English acts passed subsequently to that date, it was also held, in the first place, that Ireland was bound by all of them in which it was either specially named or included under general words. But further, inasmuch as one of the Irish acts called Poyning's Laws, passed in the tenth year of Henry VII. (A.D. 1495), in the lord-lieutenancy of Sir Edward Poyning, or Poynings, declared that all statutes 'lately' made in England should be deemed also good and effectual in Ireland, it was held that this established the authority in Ireland of all preceding English statutes whatsoever; making those enacted since the 12th of John of the same force with those enacted before that date. This however was admitted to be the last general imposition of the laws of England upon Ireland. Of the English statutes passed since the 10th of Henry VII., it was allowed that those only were binding upon Ireland in which that country was specially named or included under general words.

But the above-mentioned was only one of Poyning's laws. Others provided, as their substance is given by Blackstone (1 *Com.*, 102): '1. That before any (Irish) parliament be summoned or holden, the chief governor and council of Ireland shall certify to the king, under the great seal of Ireland, the considerations and causes thereof, and the articles of the acts proposed to be passed therein. 2, That after the king, in his council of England, shall have considered, approved, or altered the said acts, or any of them, and certified them back under the great seal of England, and shall have given licence to summon and hold a parliament, then the same shall be summoned and held; and therein the said acts so certified, and no other, shall be proposed, received, or rejected.' It was found however, in the course of time, that many inconveniences were occasioned by these severely restrictive regulations, which prevented any laws from being proposed, except only such as were drawn up before the parliament which should pass them was in being; and therefore, by the 3 & 4 Ph. and M., c. 4, it was provided that any new propositions might be certified to England for approval, even after the summons and during the session of parliament. Still this left to the parliament of Ireland nothing more than merely the power of rejecting any law proposed to it; it could neither initiate a new law nor repeal an old one, nor even amend or alter that which was offered for its acceptance. In practice however the letter of the statute was somewhat relaxed. Blackstone goes on to state that the practice in his day (some years after the middle of the last century) was, 'that bills are often framed in either house, under the denomination of "heads for a bill or bills," and in that shape they are offered to the consideration of the lord-lieutenant and privy-council, who, upon such parliamentary intimation, or otherwise upon the application of private persons, receive and transmit such heads, or reject them without any transmission, to England.' These heads of bills however really differed in nothing from bills or acts of parliament, except that, instead of the words 'Be it enacted,' the formal commencement of each paragraph or clause was, 'We pray that it may be enacted;' and the motion for presenting them scarcely differed, except in form, from the motion in the English House of Commons for leave to bring in a bill, a motion necessary in all cases to be assented to or carried in the affirmative before the actual bringing in of any bill. And as for the consent of the crown or the government, which it was necessary to obtain before either house of the Irish parliament could take up the consideration of any proposed law, with a view to its enactment, that would in practice probably be found to operate much in the same way with the assent of the crown, which even in England was necessary to give validity to any bill after it had passed both houses. In the Irish as well as in the English parliament there was in fact an opportunity of discussing the proposition without the permission of the crown. An English as well as an Irish bill required the assent of the crown before it could become law. This view of the matter has scarcely been sufficiently attended to in comparing the circumstances of the two legislatures. The practice of presenting heads of bills however was not introduced into the Irish parliament till after the Revolution. In the reign of Charles II., according to Lord Mountmorres, 'the council framed bills altogether; a negative alone on them and their several provisos was left to parliament; only a general proposition for a bill, by way of address to the lord-lieutenant and council, came from parliament:' that is to say, all that the parliament was suffered to do was simply to request that some measure might be brought in for effecting a particular object. The object might be specified, but the means by which it was to be attained or attempted, in other words, the details and whole character of the measure, were to be left to the government. With regard to these, the parliament had only the power of accepting or rejecting them in the mass.

But the dependence of Ireland upon the English crown, and the consequent subordination of the Irish legislature, were held to go still farther than to the establishment of the principle that laws might be made by the parliament of England to bind Ireland. The Irish House of Lords had entertained writs of error upon judgments in the courts of common law from the reign of Charles I., and appeals in equity from the Restoration. Nevertheless, in the year 1719, a judgment in the Court of Exchequer having been reversed by the House of Lords, the question was carried to the House of Lords of Great Britain, by which the judgment of the Court of Exchequer was affirmed. On this the Irish House of Lords resolved that no appeal lay from the Court of Exchequer in Ireland to the parliament of Great Britain. But this resolution was immediately met by an act of the British parliament, the 5 Geo. I., c. 1, declaring that 'the king's majesty, by and with the advice and consent of the lords spiritual and temporal of Great Britain in parliament assembled, had, hath, and of right ought to have full power and authority to make laws and statutes of sufficient force and validity to bind the people and the kingdom of Ireland; and that the House of Lords of Ireland has not nor of right ought to have any jurisdiction to judge of, reverse, or affirm any judgment, sentence, or decree given or made in any court within the said kingdom; and that all proceedings before the said House of Lords upon any such judgment, sentence, or decree are and are hereby declared to be utterly null and void to all intents and purposes whatsoever.'

In this state the law remained till the year 1782. In that year the statute 5 Geo. I., c. 1, was repealed by the 22 Geo. III., c. 53; and the following year the 23 Geo. III., c. 28, declared the exclusive right and authority of the Irish parliament and courts of justice in all matters of legislation and judicature for Ireland. Finally, in 1800, by the Act of Union, the 39 and 40 Geo. III., c. 67, the Irish parliauntil was extinguished; and it was enacted that the United Kingdom should be represented in one and the same parliament, to be called the parliament of the United Kingdom of Great Britain and Ireland.

The earliest Irish statutes on record are of the year 1310; but from that date there are none till the year 1429, from which time there is a regular series. The whole have been printed, and there are also abridgments by Bolingbroke and Belcher, Hunt, and others.

(Lord Mountmorres's *History of the Irish Parliament*; Blackstone's *Commentaries*; Oldfield's *Representative History of Great Britain and Ireland*; Wakefield's *Account of Ireland*; Hallam's *Constitutional History of England*.)

PARMA, DUCHY OF, a sovereign state in Northern Italy, which extends from the Apennines to the Po, and forms part of the great basin of that river. It is bounded on the north by Austrian Lombardy, from which it is divided by the course of the Po, on the east by the duchy of Modena, on the west by the Sardinian territory, and on the south partly by the Riviera of Genoa, partly by the Tuscan territory of Pontremoli, and partly by the Modenese district of Lunigiana. [MODENA.] The length of the duchy from east to west is about 80 miles, and its breadth is from 30 to 45 miles; the area is reckoned at 2280 square miles. The state of Parma consists of three territories which were formerly separate states, namely Parma, Piacenza, and Guastalla; and it is divided for administrative purposes into five districts, namely—1, Parma, which contains 32 communes and 141,270 inhabitants; 2, Piacenza, 30 communes and 127,140 inhabitants; 3, Borgo San Donnino, 25 communes and 124,300 inhabitants; 4, Borgo Taro, 11 communes and 43,650 inhabitants; 5, Guastalla, 4 communes and 29,240 inhabitants. The whole population of the state is 465,520 inhabitants, of whom about 300,000 live in the plain of the Po, 47,000 in the hilly part of the country along the lower offsets of the Apennines, and 118,000 in the highlands or mountains and valleys of the Apennines. (Serristori, *Statistica d'Italia*, 1836.) The mountain region, which constitutes about one-third of the whole country, is rugged, poor in produce, and bleak in winter; the forests of chestnut-trees which clothe the sides of the mountains supply the inhabitants with their chief article of food. Thousands of these highlanders quit their homes every year, many to seek employment in other and often distant countries, whilst others emigrate with their flocks to pass the winter in the lowlands. Many of the Italian boys who go about England and France with organs, monkeys, &c., come from the mountains of Parma. The lower hills and plains, which extend between the Apennines and the Po, and along the southern bank of that river, are very fertile, well cultivated, and populous; the lands have the advantage of a regular system of artificial irrigation by means of canals and sluices, as in Piedmont. The pasture-lands are remarkably rich. The principal products are corn of every kind, part of which is exported; pulse, fruit, wine, some of which is of a superior kind; silk, wool, cattle, and poultry. The horned cattle of the state of Parma are remarkably fine, and considerable numbers are exported. The rich cheese, known all over Europe by the name of Parmesan, is not made in the state of Parma, but in the province of Lodi in the Milanese territory; the name of Parmesan has been given to it, as it is said, because at one time Parma used to be the great mart for its sale. Good cheese however is made in the territory of Parma. The mineral wealth of the country consists of iron and copper mines near Bardi, where there are iron furnaces; salt-springs near Salso Maggiore, from which 10,000 cwt. of salt are made yearly; stones for lithography; marble and alabaster. The manufactures are few, and consist of paper, gunpowder, woollen cloth, glass, and delft ware.

The Ligurian Apennines, which in the Eastern Riviera are grouped in large masses, covering a considerable surface of country between the sources of the Scrivia, the Trebbia, the Nure, and the Taro, enter the state of Parma from the south; the central ridge runs in an eastern direction along the southern boundary of the duchy, separating the sources of the Taro, which run into the Po, from those of the Magra, which flows into the Mediterranean, and detaching various offsets to the north-east towards the Po. Between these offsets flow numerous streams, all of which are affluents of the Po; and though nearly dry in seasons of drought, become impetuous torrents during the rains. The first stream on entering the state of Parma from the west by the high road from Alessandria and Voghera to Piacenza, is the Tidone, which has a short course, the Apennines here approaching near to the Po. Farther to the east is the Trebbia, a larger stream, which has its sources at Montebruno, in the Apennines of the Riviera of Genoa, and flows northwards by Bobbio, a small town and a bishop's see in the Sardinian territory. Bobbio was once celebrated for its monastery, one of the oldest in Italy, now suppressed, and for its library, among the MSS. of which, transferred to the Ambrosian library at Milan, have been found several palimpsests, deciphered by Mai. The Trebbia then enters the state of Parma, and after a course of about 50 miles joins the Po above Piacenza. The Trebbia has an historical name. On the banks of this river Hannibal defeated the consul Sempronius; and here also Suwarrow defeated the French under Macdonald after three days' desperate fighting, on the 17th, 18th, and 19th of June, 1799, in which the French lost 6000 killed or wounded, and 3000 prisoners, whilst the Austro-Russians had about an equal number of killed and wounded. East of the Trebbia flows the Nure, which enters the Po below Piacenza. Farther east is the Taro, the largest river of the state of Parma, which rises in the Ligurian Apennines, and after flowing through a deep and long valley called by its name, and passing by Fornovo (where Charles VIII. of France, in his retreat, defeated the Venetians and their allies, in July, 1495), enters the plain of Parma near Castel Guelfo, and joins the Po after a winding course of about 60 miles. A road leads from the Val di Taro to Pontremoli and Sarzana in the valley of the Magra, passing over the Apennines of La Cisa at an elevation of about 3000 feet. The other rivers of the duchy are the Parma, which flows through the capital, and the Lenza, which forms the boundary between Parma and Modena.

The principal towns are:—1, PARMA; 2, PIACENZA; 3, Borgo San Donnino, a bustling town in a fertile plain, with 3000 inhabitants, a bishop's see, a gymnasium, and a clerical seminary; 4, Fiorenzuola, with 3000 inhabitants and a gymnasium; 5, Borgo Taro, the chief town of a district in the highlands of the Apennines, with about 1600 inhabitants, two elementary schools, and an old castle. The fortress of Compiano, situated in the neighbouring mountains, was one of Napoleon's state prisons for political offenders. 6, Guastalla, situated on the river Crostolo, not far from the Po, at the eastern extremity of the state; its small territory is confined between the Modenese state and the Po; it is a bishop's see, has a cathedral, a clerical seminary, a public library of 6000 volumes, and about 3000 inhabitants. Guastalla was for a long time a separate duchy, the history of which has been written by Father Affò, the historian of Parma. A very good map of the state of Parma was published at Milan in 1828.

PARMA, the capital of the duchy of Parma, situated in a fine plain about 12 miles south of the Po, is rather more than four miles in circumference, and is surrounded by walls and ditches; it is a bishop's see, and has 35,000 inhabitants. The streets are wide and straight, but appear somewhat dull and deserted. Parma has a 'scuola superiore,' or lyceum, with chairs of theology, medicine, and philosophy, attended by about 300 students; a secondary or grammar school, two colleges for boarders, besides a military college, a school for the arts, a house of education for young ladies, seventeen elementary schools for boys and seven for girls. The public library, which was opened in 1770, contains 80,000 printed volumes and 4000 MSS.; it was increased in 1816 by the purchase of the library of the Hebraist De Rossi, consisting of 3400 volumes, many of which are Hebrew and other Oriental MSS. (*Manuscripti Cod. Hebraici Biblioth. J. Bapt. De Rossi, accurate ab eodem descripti et illustrati*, 3 vols. 8vo., Parma, 1803-4.) Among the curiosities in the Parma library is a Koran which was found in the tent of the grand-vizier Kara Mustapha when he was defeated by Sobiesky under the walls of Vienna, and a Hebrew psalter which once belonged to Luther, with his interlinear and marginal annotations. The library of Parma has had in succession three learned librarians, well known for their literary works, Paciaudi, Affò, and Pezzana. The museum has 20,000 medals, and many inscriptions, bronzes, and other remains of antiquity, dug up at Veleia (VELEIA), an ancient town situated at the foot of the Apennines, south of Piacenza, near the village of Macinesso, not far from the river Nure.

The Ducal Gallery has many valuable paintings by Correggio, Guercino, the Caracci, Parmigiano, and other great masters: among the rest is the celebrated St. Jerome, by Correggio, which was sent to Paris by Bonaparte, but was restored in 1815; and the beautiful Madonna, called Della Scodella, another masterpiece of that great artist. The ducal palace has nothing remarkable in its architecture.

Most of the churches of Parma are adorned with paintings by Correggio. The most remarkable buildings are:—the cathedral; the Baptistery, which is built of marble and adorned with numerous statues and frescoes; St. John the Evangelist; l'Annunziata; and la Madonna della Steccata, which contains the tombs of the dukes of Parma, among others that of Alessandro Farnese. In the convent of St. Paul is an apartment exquisitely painted by Correggio, and the Palazzo del Giardino is adorned with frescoes by Agostino Carracci and Cignani. The great theatre Farnese, the largest in Italy, has not been used for many years, and is now in a dilapidated state. A new theatre, of more moderate dimensions, and better suited to a town of the size of Parma, was finished in 1829. The printing establishment of the late Bodoni deserves to be visited; his splendid editions have however much fallen in price of late years. Several palaces belonging to the nobility also deserve notice.

Parma has a Monte di Pietà, founded in 1488 by Father Bernardino da Feltre, a philanthropist who invented this kind of institution for the accommodation and relief of the labouring classes. Among the other beneficent institutions of Parma are—an hospital for incurable patients, a school of mechanical trades, a house for the poor, another for the insane, and a school for midwives, all founded by the present duchess, Maria Louisa.

The country residence of the dukes at Colorno, a few miles to the north of Parma, consists of a large mansion with extensive gardens: another villa, called Casino dei Boschi, near Sala, to the south of the capital, seems to be preferred by the present duchess as a summer residence. Selva Piana, a wood 15 miles distant from Parma, on one of the lower offsets of the Apennines, with a magnificent view, was a favourite residence of Petrarch; but the house in which he lived no longer exists.

History.—Parma was once a town of the Etruscans, and afterwards of the Boii: it was made a Roman colony at the same time as Mutina (Modena), B.C. 183. (Livy, xxxix. 55.) Martial speaks in several places of the abundance of its flocks and the fineness of their wool; and Pliny extols the salubrity of the climate. Of the antient town of Parma nothing remains except two milliary columns, which are in the little square near the church of La Steccata, a sarcophagus, and a cippus, with an inscription, in which Parma is styled 'Colonia Augusta.' (Valéry, *Voyages Littéraires*, b. viii., c. 10.) These two last monuments stand in front of the cathedral.

After the fall of the Western Empire, Parma was subject successively to the Goths, the Longobards, and the Carlovingians; it afterwards governed itself, for a time, as a republic, like its neighbours of Piacenza, Modena, Reggio, and Bologna, and it generally sided with the Guelph party and the popes. It sustained a long siege against Frederic II., who was defeated under the walls by an allied force of Bologna, Modena, and other Guelph towns. Parma afterwards was possessed in succession by the Visconti of Milan, and by Can della Scala, lord of Verona, after whose death the citizens placed themselves under the allegiance of the pope; but in 1334 the family of Correggio drove away the papal governor, and took possession of the government. It afterwards returned under the dominion of the Visconti, and then came under the Sforza, dukes of Milan. Louis XII. of France, having conquered the duchy of Milan, took Parma also; but in 1512, Pope Julius II., having driven away the French, took Parma and Piacenza, and annexed both to the papal dominions. Francis I. having conquered the duchy of Milan, Pope Leo X. gave up to him Parma and Piacenza; but Leo having afterwards joined Charles V. against the French, the latter were again driven away from Italy, and Parma and Piacenza returned to the papal allegiance. Pope Paul III., in 1545, created his son, Pier Luigi Farnese, duke of Parma and Piacenza, tributary however to the see of Rome; but the emperor Charles V., who, as duke of Milan, asserted his claims over Parma and Piacenza, refused to grant him the investiture, and the question of the sovereign dominion over Parma continued for centuries to be a subject of controversy between the House of Austria and the popes. The dukes Farnese soon found that it was their interest to be on good terms with their powerful neighbours the Austrian sovereigns of Milan, especially as the succeeding popes had no longer any tie of connection or interest with the Farnese family. Odoardo Farnese had even a serious quarrel and a kind of war with Pope Urban VIII. on account of his territories of Castro and Ronciglione. [**FARNESE.**]

In 1707, the duke Francesco Farnese having acknowledged himself a feudatory of the emperor, and as such having paid him tribute, Pope Clement XI. protested against this measure, and even issued a bull of excommunication against the Austrian troops and their commanders, who were at that time quartered in the state of Parma, which Clement qualified as a territory under the sovereignty of the see of Rome. The emperor Joseph I. replied, by a spirited declaration, that the states of Parma and Piacenza were old dependencies of the crown of Italy, and that the dukes Farnese had repeatedly acknowledged this by asking and receiving the investiture from the emperors his predecessors. (*Istoria del Dominio Temporale della Sede Apostolica nel Ducato di Parma e Piacenza*, libri iii., fol., Rome, 1720.) The whole history of the controversies between the court of Rome, the dukes Farnese, and the House of Austria, on account of Parma and its dependencies, is very curious. Botta, in his 'Storia d'Italia,' books vii., viii., ix., xxiii., xxxvi., xxxviii., and xlvii., notices these transactions at some length.

The dynasty of Farnese continued to reign at Parma and Piacenza till the extinction of the male line of that family in 1731. Elizabeth Farnese however, wife of Philip V. of Spain, claimed the duchy for her son the infant Don Carlos, to whom the last duke had bequeathed it. The pope protested; but his protest was disregarded, and Don Carlos took possession of Parma in 1732. In the subsequent war of the Austrian succession, Parma and Piacenza were taken by the Austrians, and afterwards retaken by the Spaniards in 1745. By the peace of Aix-la-Chapelle, 1748, Don Carlos having become king of the Two Sicilies, his younger brother the infante Don Philip was acknowledged as duke of Parma, Piacenza, and Guastalla. Philip, with the assistance of his minister Dutillot, administered his states with great wisdom. He died in 1765, and was succeeded by his son Don Ferdinand, during whose minority the minister Dutillot proceeded in the same system of gradual reforms, and Parma was one of the most thriving and best governed states of Italy.

At Ferdinand's accession a repetition of the usual controversy took place with the court of Rome concerning the tribute which the latter demanded as an acknowledgment of vassalage, but Dutillot resisted the claim. Then came another controversy concerning an edict of the duke, prohibiting appeals to the tribunals of Rome, and forbidding the publication of papal bulls and briefs without his own 'exequatur.' One of the best written publications on this occasion was by Professor Contini in defence of the independence of the duchy. Ferdinand, after he came of age, dismissed Dutillot, and gave himself up to the guidance of the clergy, and occupied himself much more with devotional practices than with the affairs of the administration. When Bonaparte invaded Italy in 1796, the Duke of Parma professed neutrality, which however he was made to purchase by giving up twenty of his most valuable paintings, besides two millions of francs, several thousand head of cattle, corn, and other provisions for the French army. Notwithstanding this the country was occupied by French troops, and in 18[illegible] a treaty was concluded between France and Spain, by which the state of Parma was to be given up to France at the death of the duke, and Ferdinand's son, Ludovico, was proclaimed king of Etruria, that is, Tuscany. Duke Ferdinand died in the following year, upon which Bonaparte ordered his agent Moreau de St. Méry to take possession of that state and administer it for the time. In 1805 Parma and Piacenza were definitively united with the French empire, under the name of the department of the Taro. The new king of Etruria, Ludovico, having died in 1803, his widow, Maria Luisa of Spain, administered the kingdom for her infant son Carlo Ludovico, till 1808, when they were both unceremoniously removed from Tuscany by Napoleon, and sent in a kind of banishment to France. After the fall of Napoleon in 1814, the Congress of Vienna decided that the duchy of Parma and Piacenza should be the apanage of his wife Maria Louisa of Austria during her lifetime; that the ex-queen of Etruria and her son should have the duchy of Lucca; and that after the death of Maria Louisa of Austria, the Duke of Lucca should be restored to his paternal states of Parma, and Lucca be annexed to the grand-duchy of Tuscany.

Parma is therefore at present under the government of Maria Louisa, archduchess of Austria and former empress of France. The government of this princess is generally acknowledged to be mild and adapted to secure the welfare of the people. New codes have been compiled and published. The civil code is liberal in its spirit; the penal code is rather severe, especially with regard to political offences; trials are public. There are civil and criminal courts at Parma and Piacenza, and a court of appeal in each of these towns.

The revenue amounts to about seven millions of livres, or 280,000 pounds sterling; there is a funded debt of 10,700,000 livres. The military establishment consists of about 1000 men.

The number of the secular or parochial clergy is 2470, and that of the parishes 763; the number of monks and friars is 479, and that of nuns 245. (Serristori, *Statistica d'Italia.*) The number of boys and girls who attend the elementary schools is about 9780. Twenty-five communes are still without schools.

(Valery; Neigebaur; Affò, *Storia della Città di Parma*, 4 vols. 4to., 1792; Affò, *Memorie degli Scrittori e Letterati Parmigiani*, 5 vols. 4to., continued by Pezzana; Donato, *Descrizione del Gran Teatro Farnesiano di Parma*, 4to., 1817; *Fiore della Ducale Galleria Parmense*, published by Toschi in fol.; Donato, *Nuova Descrizione della Città di Parma*, 8vo., 1824; Cortesi, *Saggi Geologici degli Stati di Parma e Piacenza*, 4to., 1819, with plates.)

PARMA, DUKE OF. [FARNESE.]

PARMACELLA. [LIMAX, vol. xiii., p. 487.]

PARME'NIDES (*Παρμενίδης*), the second in the series of the Eleatic philosophers, was a native of Elea. He was descended from a noble family, and is said to have been induced to study philosophy by Ameinias. (Diog. Laert., ix. 21.) He is also stated to have received instruction from Diochætas, the Pythagorean, to whom he erected an heroum. Later writers inform us that he heard Xenophanes, the founder of the Eleatic school, but Aristotle (*Met.*, i. 5) speaks of it with some doubt. We read that Parmenides gave a code of laws to his native city, which was so highly esteemed that at first the citizens took an oath every year to observe it. (Diog. Laert., ix. 23; Plut., *Adv. Colot.*, 32; Strabo, vi., p. 252, Casaub.)

The time when Parmenides lived has been much disputed. According to Plato (*Parmenid.*, p. 127), Parmenides, at the age of sixty-five, accompanied by Zeno, at the age of forty, visited Athens during the great Panathenæa, and stopped at the house of Pythodorus. As this visit to Athens probably occurred about B.C. 454 (Clinton, *Fast. Hell.*, p. 364), Parmenides would have been born about B.C. 519. But to this date two objections are urged; first, that Diogenes Laertius (ix. 23) says that Parmenides flourished (ἤκμαζε) in the 69th Olympiad, that is about B.C. 503; and consequently if he was born B.C. 519 he would only have been about sixteen in the 69th Olympiad; and secondly, that Socrates is stated by Plato in the dialogue entitled Parmenides, to have conversed with Parmenides and Zeno on the doctrine of ideas, which we can hardly suppose to have been the case, as Socrates at that time was only thirteen or fourteen. Athenæus (xi., p. 505) accordingly has censured Plato for saying that such a dialogue ever took place. But in reply to these objections it may be remarked, first, that little reliance can be placed upon the vague statement of such a careless writer as Diogenes; and secondly, that though the dialogue which Plato represents Socrates to have had with Parmenides and Zeno is doubtless fictitious, yet it was founded on a fact that Socrates when a boy had heard Parmenides at Athens. Plato mentions, both in the 'Theætetus' (p. 183) and the '*Sophistes*' (p. 127) that Socrates was very young (πάνυ νέος) when he heard Parmenides.

We have no other particulars respecting the life of Parmenides. He taught Empedocles and Zeno, and with the latter he lived on the most intimate terms. (*Plat., Parm.*, 127.) He is always spoken of by the ancient writers with the greatest respect. In the 'Theætetus' (p. 183) Plato compares him with Homer; and in the '*Sophistes*' (p. 237) he calls him 'the Great.' (Compare Aristot., *Met.*, i. 5.)

Parmenides wrote a poem, which is usually cited by the title 'On Nature'—*περὶ φύσεως* (Sext. Empir., *Adv. Mathem.*, vii. 111; Theophrastus, *Ap. Diog. Laert.*, viii. 55), but which may have other titles. Suidas (*Parmenid.*) calls it φυσιολογίαν, and says, on the authority of Plato, that he also wrote works in prose. The passage of Plato (*Soph.*, p. 237) however, to which Suidas refers, perhaps only means an oral exposition of his system, which interpretation is rendered more probable by the fact that Sextus Empiricus (*Adv. Mathem.*, vii. 111) and Diogenes Laertius (i. 16) expressly state that Parmenides only wrote one work. Several fragments of this work, 'On Nature,' have come down to us, principally in the writings of Sextus Empiricus and Simplicius. They were first published by Stephanus in his '*Poesis Philosophica*' (Par., 1573), and next by Fülleborn, with a translation in verse, Züllichau, 1795. Brandis, in his 'Commentationes Eleaticæ,' Hafniæ, 1813, also published the fragments of Parmenides, together with those of Xenophanes and Melissus, but the most recent and most complete edition is by Karsten, in the second volume of his 'Philosophorum Græcorum veterum, præsertim qui ante Platonem floruerunt, Operum Reliquiæ,' Brux., 1835.

The fragments of his work which have come down to us are sufficient to enable us to judge of its general method and subject. It opened with an allegory, which was intended to exhibit the soul's longing after truth. The soul is represented as drawn by steeds along an untrodden road to the residence of Justice (Δίκη), who promises to reveal everything to it. After this introduction the work is divided into two parts; the first part treats of the knowledge of truth, and the second explains the physiological system of the Eleatic school, of which an account is given under ELEATIC PHILOSOPHY.

PARME'NIO, a Macedonian general, who distinguished himself in the service of Philip, father of Alexander the Great. He gained a decisive victory over the Illyrians, about the time of Alexander's birth, and the news of both events reached Philip, who was then absent from his capital on some expedition, together with that of his having won the prize at the Olympic games. Philip, while preparing to invade the Persian empire, sent a considerable force into Asia as an advanced guard, and he chose Parmenio and Attalus as the leaders of the expedition. These commanders began by expelling the Persian garrisons from several Greek towns of Asia Minor. Parmenio took Grynium in Æolis, the inhabitants of which, having sided with the Persians, and fought against the Macedonians, were sold as slaves. When Alexander set out on his Asiatic expedition, Parmenio had one of the chief commands in the army. At the head of the Thessalian cavalry he contributed materially to the victory of the Granicus; and at Issus he had the command of the cavalry on the left wing, which was placed near the sea-coast, and had to sustain for a time the principal attack of the Persians. In the field of Gaugamela, he advised Alexander not to give battle until he had well reconnoitred the ground. Being in command of the left wing, he was attacked in flank by the Persians, and was for a time in some danger, until Alexander, who had been successful in another part of the field, came to his assistance. Parmenio afterwards pursued the fugitives, and took possession of the Persian camp, with the elephants, camels, and all the baggage. When Alexander marched beyond the Caspian gates in pursuit of Darius and Bessus, he left Parmenio, who was now advanced in years, in Media, at the head of a considerable force. Some time after, whilst Alexander was encamped at Artacoana, a conspiracy is said to have been discovered against his life. The informer was a boy of infamous character, and the persons accused were officers, though not of exalted rank. The informer said that he had first told his secret to Philotas, the son of Parmenio, who had daily access to Alexander, but who had taken no notice of it for two days, at the end of which time, through the means of another officer near Alexander's person, the information was conveyed to the king. This threw strong suspicion upon Philotas, who however was not implicated by either the informer or any of the accused in their confessions. But Craterus, who had an old jealousy against Philotas, on account of the favour the latter enjoyed with the king, encouraged the suspicions of Alexander, who recollected what Philotas had said at the time when he claimed Jupiter Ammon for his father—he pitied those who were doomed to serve a man who fancied himself a god. Craterus had also for some time previous bribed a courtesan kept by Philotas, who reported to him, and through him to the king, all the boastful vapourings and expressions of discontent uttered by Philotas in his unguarded moments. In short, Alexander, according to Curtius, was induced to order Philotas to be tortured, in consequence of the suggestions of Craterus, Hephæstion, and others of the king's companions. Cœnus, who had married the sister of Philotas, was one of the most violent against the accused, for fear, it was supposed, of being thought an abettor of his brother-in-law. The torture was administered by Craterus himself, and Philotas, after enduring dreadful agonies, confessed, though in vague terms, that he had conspired against the life of Alexander, and that his father Parmenio was cognizant of it. This being considered sufficient evidence, Philotas was stoned to death, and Alexander despatched a messenger to Media with secret orders to Cleander and other officers who were serving under Parmenio, to put their commander to death. The unsuspecting veteran, while conversing with his officers, was run through the body by Cleander. This is the substance of the account of Curtius (vi. and vii.), a compiler by no means unfavourably disposed towards Alexander.

Arrian, after stating that he derived his knowledge of these occurrences from the work of Ptolemy, briefly says that Philotas was charged by Alexander, before the assembled Macedonians, with having conspired against him: that Philotas at first succeeded in justifying himself, but that afterwards fresh evidence was produced to criminate him, and among other arguments urged against him on his trial, one of the strongest was, that having received information of a plot against the king's life, he did not reveal it, although he had access to Alexander's person twice a-day. The result of the trial was that Philotas and his accomplices were run through with spears by the Macedonians. Alexander despatched Polydamanthus to Media with letters for Cleander, Sitalces, and Menides, three officers who were serving under Parmenio. Parmenio was put to death, pursuant to the orders of Alexander: 'Whether it was,' Arrian observes, 'that Alexander thought it unlikely that Parmenio should be ignorant of the treachery of his son Philotas, or that, even if he was ignorant of it, it appeared to Alexander a dangerous thing to leave him alive after the execution of his son, especially as Parmenio's authority was so great with the troops, both Macedonian and auxiliary.' (Arrian, b. iii.)

Whatever may be thought of the trial and execution of Philotas, and it appears to have been at least a summary and unsatisfactory proceeding, the murder of Parmenio and the manner of it form one of the darkest blots in Alexander's character. Parmenio was evidently sacrificed in cold blood to what have been styled in after-ages 'reasons of state.' He was seventy years of age; he had lost two sons in the campaigns of Alexander, and Philotas was the last remaining to him. Parmenio appears to have been a steady, brave, and prudent commander.

An instance of the careless manner in which history has been often commented upon, even by writers of eminence, appears in Montesquieu (*Esprit des Lois*, x. 14), where he sums up the character of Alexander by saying that 'he committed two bad actions, burning Persepolis and killing Cleitus, but he expiated both by his repentance, so that they came to be looked upon rather as misfortunes than as crimes.' Montesquieu says nothing of the murder of Parmenio, nor of that of Callisthenes, deeds of darker guilt than those which he mentions, the former of which is doubtful, and the second has at least the excuse of being the result of a drunken brawl.

PARMIGIA'NO, FRANCESCO MAZZUOLI, sometimes called, in the diminutive form, PARMIGIANINO, was born at Parma in 1503, and was the son of Filippo Mazzuoli, called dell' Erbette. He studied painting under his uncles Michele and Filippo and his countryman Marmitta. In his sixteenth year he finished a picture of the Baptism of Christ, now in the palace of Count Sanvitati. Correggio's visit to Parma in 1521 made him acquainted with the style of that master. In 1522 he painted, among other works, a Madonna with the Child, and St. Jerome and St. Bernardin (in the convent Della Nunziata), but which has suffered from time and the hands of unskilful restorers. In hopes of giving Pope Clement VII. proofs of his skill, he went in 1523 to Rome, where the sight of the works of Raphael made a deep impression on him. In his subsequent works he endeavoured to combine with the grace of Raphael the contrasts of Michael Angelo and the grace and harmony of Correggio; whence he was called Il Raffaellino. On the taking of Rome, 1527, when he sustained considerable loss, he went to Bologna, where the engraver Fantuzzi, commonly called Antonio de Trento, stole several of his drawings, which was afterwards found in the collection of the Earl of Arundel, and brought back to Italy by Count Zanetti, who published them in 1749, admirably cut on wood and printed in colours.

Among the finest works executed by Parmigiano in Bologna were St. Rochus, painted for the church of St. Petronius, the Madonna della Rosa, now in the Dresden Gallery, which he had changed from a Venus to a Madonna, and the St. Margaret. He afterwards returned to his own country, where he painted the Cupid fashioning his bow, with two infants at his feet, one laughing, and the other crying, of which there are numerous repetitions; and began to adorn with several paintings the newly built church Della Steccata. But his health being greatly weakened, he was unable to work, and the directors of the building threw him into prison, as he had received a sum of money in advance. They indeed set him at liberty on his promise to complete the work; but indignant at this treatment, he fled to Casal Maggiore, where he died in 1540. His works, especially his easel pieces, are very scarce. The predominant features of his style are elegance of form, grace of countenance, contrast in the attitudes, perfect knowledge of the chiaroscuro, and the charm of colour. But his figures are often characterised by excessive slenderness rather than real elegance of form, and his grace sometimes degenerates into affectation and his contrasts into extravagance. His taste was exquisite, but it led him to imitate the effects rather than the principles of his masters. Parmigiano was celebrated for the care and freedom with which he designed, and for those bold strokes of the pencil which Albano calls divine. There are few altar-pieces by him: the most valued is that of St. Margaret in Bologna, a composition rich in figures, which was studied by the Carracci, and which Guido even preferred to the St. Cecilia of Raphael.

The etchings of Parmigiano are universally known as models of taste, delicacy, and freedom. He has been erroneously considered as the inventor of the art of etching, which was practised by Albert Dürer before him; but he was the first who introduced it into Italy.

PARMO'PHORUS. [CERVICOBRANCHIATA, vol. vi., p. 444 et seq.]

PARNASSOS (Παρνασσός), the name of a mountain-chain in Phocis, which extends in a north-easterly direction from the country of the Locri Ozolæ to Mount Œta, and in a south-westerly direction through the middle of Phocis till it joins Mount Helicon on the borders of Bœotia. Strabo (ix., p. 316. Casaubon) says that Parnassus divided Phocis into two parts; but the name was more usually restricted to the lofty mountain upon which Delphi was situated. According to Stephanus of Byzantium it was antiently called Larnassus, because the ark or larnax of Deucalion landed here after the flood. (Compare Ovid, *Met.*, i. 318.) Pausanias (x. 6, s. 1) derives the name from Parnassus, the son of Poseidon and Cleodora. It is called at the present day Liakura.

Parnassus is the highest mountain in central Greece. Strabo says (viii., p. 379) that it could be seen from the Acrocorinthus in Corinth, and also states (viii., p. 4[illegible]) that it was of the same height as Mount Helicon; but in the latter point he was mistaken, according to Colonel Leake, who informs us (*Travels in Northern Greece*, vol. ii., p. 527) that Liakura is some hundreds of feet higher than Paleoruna, which is the highest point of Helicon. Parnassus was covered the greatest part of the year with snow, whence the epithet of 'snowy,' so generally applied to it by the poets. (Soph., *Œd. Tyr.*, 473; Eurip., *Phœn.*, 214.) When Brennus invaded Greece, we learn from Pausanias (x. 23, s. 3, 4) that it was covered with snow.

Above Delphi there were two lofty rocks, from which the mountain is frequently called by the poets the two-headed (δικόρυφος), one of which Herodotus (viii. 39) names Hyampeia, but which were usually called Phædriades. Between these two rocks the celebrated Castalian fountain flows from the upper part of the mountain, which at present 'is clear, and forms an excellent beverage. The water which oozes from the rock was in antient times introduced into a hollow square, where it was retained for the use of the Pythia and the oracular priests. The fountain is ornamented with pendant ivy, and overshadowed by a large fig tree.' (Dodwell's *Travels*, vol. i., p. 172.) Above the spring, at the distance of 60 stadia from Delphi, was the Corycian cave, sacred to Pan and the Corycian nymphs, which Pausanias (x. 32, s. 2, 5) speaks of as superior to every other known cavern. (Compare Strabo, ix., p. 417.) When the Persians were marching against Delphi, a great part of the inhabitants took refuge in this cavern. (Herod., viii. 36.) It is described by a modern traveller (Raikes, in Walpole's *Collection*, &c., vol. i., p. 312) as 330 feet long and nearly 200 wide. As far as this cave the road from Delphi was accessible by horses and mules, but beyond it the ascent was difficult even for an active man (ἀνδρὶ εὐζώνῳ; Paus., x. 32, s. 5, 6). Above this cave, and near the summit of Parnassus, at the distance of 80 stadia from Delphi (Paus., x. 32, s. 6), was the town of Tithorea or Neon, the ruins of which are near the modern village of Velitza. For an account of the towns in the neighbourhood of the Parnassus, see PHOCIS.

PARNELL, THOMAS, was born in Dublin in 1679. He entered Trinity College, Dublin, at the age of 13, and became Master of Arts in 1700. In the same year, though under the canonical age, he was ordained a deacon, a dispensation having been granted by the bishop of Derry. About three years afterwards he took priest's orders, and in 1705 received the archdeaconry of Clogher from Dr. Ashe, the bishop of the diocese. Nearly at the same time he married Mrs. Anne Minchin, by whom he had two sons and a daughter. Parnell was on a familiar footing with the leading wits of the time of Queen Anne. On the ejection of the Whigs towards the close of her reign, he abandoned that party, to which he had been previously attached, and was cordially welcomed as an adherent by the Oxford administration. His hopes of preferment from this quarter however were disappointed by the dismissal of the Tories from office on the death of the queen. Thereafter he is represented to have fallen into intemperate habits, occasioned, it is said, chiefly by the untimely death of one of his sons, or the loss of his wife, who died in 1712. On the recommendation of Swift, he obtained a prebend from Archbishop King in 1713; and in May, 1716, was presented to the vicarage of Finglass. He died at Chester, on his way to Ireland, in July, 1717, in the 38th year of his age. A selected edition of his poems was published by Pope soon after his death, and dedicated to the earl of Oxford. A volume, said to contain his posthumous works, the authenticity of which is doubtful, appeared in Dublin in 1758. As a poet, Parnell is principally remarkable for the smoothness and ease of his versification, and the elegance and purity of his sentiments. The pieces on which his fame must rest are, the 'Rise of Woman,' the 'Fairy Tale,' the 'Hymn to Contentment,' 'Health,' the 'Vigil of Venus' (Pervigilium Veneris), the 'Night-Piece on Death,' the 'Allegory on Man,' and 'The Hermit.' Parnell was the author of the 'Life of Homer' prefixed to Pope's translation, certain papers in the 'Spectator' and 'Guardian,' and various unacknowledged performances.

(*Life*, by Goldsmith; *Poetical Works*, Glasg., 1786, fol.)

PARODY (from the Greek *παρῳδία*, and that from *ᾠδή*, an ode). A parody is a poetical pleasantry, which consists in turning what is intended as a serious composition into ridicule, by adapting it to some new purpose, or by the affected imitation of its peculiarities. It had its origin among the Greeks, from whose language the name is derived. It seems to be synonymous with the French *travestie*. Its most common form is that in which a performance, while its principal features are retained, is, by a slight change, diverted from its proper design, and made to bear a ludicrous signification. Sometimes the alteration of a single word, or even a single letter, is sufficient for the accomplishment of this. Another form of parody is that in which, without any change in the original, it receives a ludicrous character by its application to some object quite foreign to the original intention of the author. A third kind consists in choosing a mean and ridiculous subject, and treating it in the style and manner of approved writers; and a fourth, in exemplifying, in the illustration of any subject, the defects and absurdities of writers held in little esteem. Of the last two sorts of parody, more successful specimens will scarcely be found anywhere than those which occur in the work entitled 'Rejected Addresses.' The rules of parody have respect to the choice of the subject and the mode of handling it. It is necessary that the subject should be celebrated, or at least well known, and that in treating it there should be no departure from the requirements of good humour.

The term parody is also employed in music, and is given by the French writers to those pieces in which the words have been composed for the music and not the music for the words.

(*Mém. de l'Acad. des Belles-Lettres*, tom. 9.)

PAROL. This term, which signifies 'a word,' has been adopted from the Norman French as a term of art in English law, to denote verbal or oral proceedings, as distinguished from matters which have been recorded in public tribunals or otherwise reduced to writing. Thus a parol contract is an agreement by word of mouth, as opposed to a contract by deed. Parol evidence is the testimony of witnesses given orally, as opposed to records or written instruments. This is the popular acceptation of *parol*; but, strictly speaking, everything, even in writing, is parol which is not under seal.

The formal allegations of the parties to a suit in the common law courts, called pleadings, which are now made in writing, were formerly conducted orally at the bar, and in the year-books are commonly denominated the parol. Hence in certain actions brought by or against an infant, either party may suggest the fact of the infancy, and pray that the proceedings may be stayed; and where such a suggestion was complied with, the technical phrase was that the *Parol demurred* (demurrabat), that is, the pleadings were suspended until the infant had attained his full age.

PAROS, one of the larger Cyclades, is situated west of Naxos, from which it is separated by a channel five or six miles wide. Paros is estimated to be about one half the size of Naxos; it is about 36 miles in circumference. The surface is hilly, but the hills are not so high as those of Naxos: it produces corn, abundance of fruit, and has flocks of sheep and herds of swine, and plenty of partridges and other game. The population, according to Thiersch (*État de la Grèce*), is about 4000. It was hardly 2000 at the end of the last century, when Olivier visited the island. But Paros was then suffering under the infliction of a yearly visit from the captain-pasha's fleet, which anchored in the port for several weeks in the summer, in order to collect the capitation-tax from Paros and the neighbouring islands. During this time all kinds of oppression and extortion were practised by the Turks upon the defenceless and dispirited inhabitants. Tournefort, a century earlier, bore witness to the same kind of treatment. The head town of Paros, called Parichia, is on the site of the ancient town, in the inner recess of a bay on the north-west coast of the island. The principal harbour is on the north-east coast, and is the finest in the archipelago. The mountain Marpessa, now called Capresso, near the centre of the island, abounds with white marble, which was often used by the ancient sculptors. On a rock above the entrance of one of the quarries Tournefort saw a basso-rilievo representing, as he conjectured, a Bacchanalian feast, some of the figures of which were unfinished. There are four or five villages on the island, besides the capital, and several Greek monasteries scattered about.

Paros is said to have been colonised by the Cretans, and to have been at one time called Minoa, from Minos, king of Crete. It attained a great degree of prosperity by its maritime trade, and the chief town was wealthy and well fortified. When Darius invaded Greece, the inhabitants of Paros submitted to the Persians, and furnished sailors for the Persian fleet, in consequence of which, after the battle of Marathon, Miltiades went with an Athenian squadron to attack the island; but he failed in the attempt, and received the wound of which he shortly after died. [MILTIADES.] After the defeat of Xerxes at Salamis, Themistocles obliged Paros to pay tribute to Athens. The island afterwards underwent the same vicissitudes as the rest of the Cyclades, until it fell at last under the dominion of the Romans. Paros is mentioned in the inscription of Adule among the countries subject at one time to the Ptolemies of Egypt. When the Franks took possession of Constantinople, Paros, like most of the Cyclades, became subject to the Venetians. It formed for a time part of the dukedom of Naxos, but afterwards became a separate principality of the Venetian family of Veniero, under which it remained till Barbarossa took it in the sixteenth century. During the war of Candia in the following century, the Venetians landed at Paros; but soon after abandoned it, after destroying the olive plantation, the principal wealth of the island. In the latter part of the eighteenth century, the Russians took possession of Paros, and made it for a time the station of their fleet. It now belongs to the kingdom of Greece.

The Greek inscription called the 'PARIAN CHRONICLE' was found in this island.

West of Paros, and separated from it by a narrow channel, is the smaller island called Antiparos, formerly Olearos. The island produces some corn, and contains a village which is inhabited by a few hundred people. Antiparos is noted for its natural cave or grotto, one of the largest and finest that is known. It is described by Tournefort in his 'Travels,' who gives a print of the interior

Coin of Parus.
British Museum. Actual size.

PARO'TIA. [Bird of Paradise, vol. iv., p. 420.]

PAROTID GLAND (from παρά, 'near,' and οὖς, 'the ear') is the largest of the three principal glands by which the saliva is secreted and poured into the mouth. The parotid glands are situated, one on each side of the face, behind the ascending part of the lower jaw, and below and in front of the ear. The most anterior portion of each lies upon a part of the masseter muscle, immediately beneath the skin of the face, at the most backward part of the cheek; and hence the main duct passes forwards, penetrating obliquely through the fat of the cheek and through the buccinator muscle, to open into the cavity of the mouth nearly opposite to the second molar tooth of the upper jaw. The more posterior part of the gland is placed in an intricate manner among the tissues behind the jaw and beneath the outer part of the base of the skull, fitting into the irregularities that are left between them, and in some parts passing very deeply down beneath the skin.

The structure of the parotid, like that of all the glands secreting saliva, is lobulated, being made up of a number of minute cells, the terminations of the branches of the main duct, upon whose walls a net-work of capillary blood-vessels is arranged, and which are collected together in uncertain numbers to form the several lobules of which the whole gland is made up. [Digestion.]

The principal disease to which the parotid gland is subject is the mumps. [Mumps.] It is often attacked with inflammation and suppuration in the course of severe fevers, and is liable to be affected by the different kinds of malignant growths, as cancer, fungus hæmatodes, &c. In these cases the whole or the affected part of the gland has sometimes been removed with success, but the operation must be considered one of the most dangerous and uncertain in surgery. Wounds of the parotid duct, which, from its exposed situation, are not rare, often lead to the formation of salivary fistulæ, the constant flowing of saliva through the aperture preventing the complete healing of the skin, and thus establishing a permanent opening on the exterior of the cheek, through which the saliva flows. To prevent this evil, the sides of any wound in which it is suspected that the parotid duct is divided, should be brought together with peculiar care, and held in exact apposition by gentle compression: for its cure, when the fistulous opening is formed, an operation is generally necessary, which consists in perforating the interior of the cheek from the outer opening, and then endeavouring, by compression of the latter, to turn the course of the saliva inwards, and restore the natural passage into the mouth.

PARR, CATHERINE. [Henry VIII.]

PARR, SAMUEL, was born at Harrow-on-the-Hill, 1747, where his father was a surgeon and apothecary. He was early distinguished for his love of books and his aptitude at learning. He received his education at the grammar-school of Harrow, and gave the highest satisfaction to the masters under whom he was placed, and who predicted his future eminence. In his fifteenth year he was removed from school and put to the business of his father. But the progress he had made in classical literature, and the intellectual habits he had formed, enabled him to continue his studies with the greatest advantage and success. Being disgusted with the employment selected for him, and having early displayed a grave and serious disposition, a predilection for the clerical profession, and an attachment to ecclesiastical pomp and circumstance, it was at length determined to send him to the university. Accordingly, in 1765, in his nineteenth year, he was entered at Emanuel College, Cambridge, where he applied himself with great diligence to classical and philological pursuits. But his father dying soon after, he was compelled, before he had taken a degree, to relinquish his academic career, where so bright a prospect was opening upon him, and in 1767 became one of the assistants in Harrow School. In this situation he remained five years, with the greatest credit to himself: and on the death of Dr. Sumner, offered himself as a candidate for the vacant mastership, but without success. His youth was the ostensible, while in all probability his politics were the real objection against him in the mind of the governors. With bitterness of spirit he now left the place of his birth and the scenes of his boyhood, and kept a school successively at Stanmore, at Colchester, and at Norwich. In 1786 he settled at Hatton, in Warwickshire, to the small living of which place he had been presented; and here he spent the remainder of his life, in discharging the duties of his parish, in the instruction of youth, and in accumulating those stores of philological learning for which he became so eminently distinguished. The highest preferment he obtained in the church was a prebendal stall in St. Paul's The Whigs, to whom he had attached himself, had few opportunities of disposing of the patronage of the state; and when the occasion offered, Lord Grenville, with a base and cool ingratitude, urged against him, who had so long and so faithfully served his party, his unpopularity with the members of his profession. In fact, while he served his party, he did not attach or fix himself upon the individuals of his party.

Parr was a man of great talents, of very extensive learning, and of pre-eminent conversational powers; but he was vain, arrogant, and overbearing. His friends uniformly represent him as possessing much benevolence and kindliness of feeling; but he required the most abject submission, and exacted the most slavish attention from all who approached him, or he never hesitated about insulting and making himself exquisitely offensive to them. Neither can some of his acts be altogether reconciled with the character of generosity ascribed to him. He printed an edition of Bellendenus [Bellendenus], with a preface, in which he eulogised the eloquence and ability of the *tria lumina Anglorum*, Lord North, Fox, and Burke; but he seems to have undertaken the task rather for the sake of bearding his political foes than passing an encomium upon his political friends. He re-published 'Tracts by Warburton and a Warburtonian,' to annoy Bishop Hurd, the editor of Warburton; and felt no compunction about injuring the fame of the latter, whom he pretended to admire and respect, if he could only quarrel with the former, who had given him no offence save what an inordinate and morbid self-conceit might imagine. In his literary and political disputes he argued and declaimed with the fierceness of party-feeling and the petulance of self-love, and forgot alike both the equities and the decencies of controversy. Though of unquestioned ability, he spoke and wrote with the fluency of ready knowledge, rather than with the profoundness of original thought or the compass of a philosophic spirit. He was a determined and violent Whig, but he had no right views, no just sentiments, with respect to freedom; as his opinions on the slave trade and Test Act questions fully testify. It must be stated however that on these subjects his mind underwent a change in the latter part of his life. Still his notions about civil and religious liberty were never the clearest or the most comprehensive, for while he could recommend conciliation to the Catholics and the Unitarians, he did not hesitate to suggest persecution against the Methodists.

He left a vast mass of papers behind him, consisting of his correspondence, and of historical, critical, and metaphysical disquisition. His published writings, by Dr. Johnstone, fill eight thick 8vo. volumes. They are distinguished by copious erudition, a ready conception, and a vigorous and ample style But he has left no great work; nor will his name go down to posterity associated with any important principle or extensive literary undertaking. His fame rests upon a learning which, whatever may have been its accuracy and its extent, has bequeathed to the world no memorable results, and upon a colloquial power which, with the exception of Dr. Johnson, left him without a rival. He died in 1825, in the 79th year of his age, and was buried at Hatton.

PARRA. [Rallidæ.]

PARRAL. [Mexican States.]

PARRHA'SIUS, son and pupil of Evenor, was a native of Ephesus, but became a citizen of Athens. He raised the art of painting to perfection in all that regarded the essential. He compared his three great predecessors with one another, rejected that which was exceptionable, and adopted that which was admirable in each. The classic invention of Polygnotus, the magic tone of Apollodorus, and the exquisite design of Zeuxis, were all united in the works of Parrhasius; what they had produced in practice he reduced to theory. He so circumscribed and defined, says Quintilian (*Inst. Or.*, xii. 10), all the powers and objects of art, that he was termed the Legislator; and all contemporary and subsequent artists adopted his standard of divine and heroic proportions.

Parrhasius himself was aware of his ability: he assumed the epithet of the Elegant (Ἁβροδίαιτος), and styled himself Prince of Painters; he wrote an epigram upon himself (Athenæus, xii. p. 543, Casaub.), in which he proclaimed his birth-place, celebrated his father, and pretended that in himself the art of painting had attained perfection. He also declared himself to be descended from Apollo, and carried his arrogance so far as to substitute his own portrait in a temple as Mercury, and thus receive the adoration of the multitude. (Themist., xxi.) He wore a purple robe and a golden garland; he carried a staff wound round with tendrils of gold, and his sandals were bound with golden straps. (Ælian, *Var. Hist.*, ix. 11.) It appears then that Pliny justly terms him the most insolent and most arrogant of artists. (*Hist. Nat.*, xxxv. 10, 36.)

The branch of art in which Parrhasius eminently excelled was a beautiful outline as well in form as execution, particularly in the extremities, for, says Pliny, when compared with himself, the intermediate parts were inferior.

One of the most celebrated works of Parrhasius was his allegorical figure of the Athenian people, or Demos. Pliny says that it represented, and expressed equally, all the good and bad qualities of the Athenians at the same time; one might trace the changeable, the irritable, the kind, the unjust, the forgiving, the vain-glorious, the proud, the humble, the fierce, and the timid. How all these contrasting and counteracting qualities could have been represented at the same time, it is difficult to conceive; if we are to suppose it to have been a single figure, it is very certain that it could not have been such as Pliny has described it (xxxv. 10.36), for, except by symbols, it is totally incompatible with the means of art.

Parrhasius painted a Theseus, which, after the general spoliation of Greece, was placed in the Capitol at Rome. It was probably for this picture that he was made a citizen of Athens. When Euphranor remarked that the Theseus of Parrhasius had fed upon roses, and his own upon beef, he seems to have alluded particularly to the style of design, and not, as one might suppose, to the colour; for, as Winckelmann has observed, the word used by Plutarch (γλαφυρῶς, 'elegantly') relates expressly to form. (*De Glor. Ath.*, 2.) According to the taste of Euphranor, the figure of Parrhasius was too elegant, too delicate, too effeminate for heroic beauty.

Pliny enumerates many other works by Parrhasius; a naval commander in his armour; a Meleager, Hercules, and Perseus upon the same tablet; Ulysses feigning insanity; Castor and Pollux; Bacchus and Virtue; a Cretan nurse with an infant in her arms; a priest officiating, with an attendant youth bearing incense; two youthful boys, in whom were admirably depicted the innocent simplicity of their age, and its happy security from all care; a Philiscus; a Telephus; an Achilles; an Agamemnon; an Æneas; and two famous pictures of Hoplites, or heavy-armed warriors, one in action, the other in repose, admirably painted.

Parrhasius amused himself also with painting small libidinous pieces. The Archigallus mentioned by Pliny was most probably of this description, both from the particular favour of Tiberius with which it was honoured, and the peculiar nature of the rites of Cybele, whose chief priest was the Archigallus. To this class we may add the picture of Meleager and Atalanta, mentioned by Suetonius (*Tib.*, c. 44): this picture was bequeathed to Tiberius on the conditions that if he should be offended with the subject, he should receive in its stead 1,000,000 sesterces ('decies H-S,' about 8000*l.*). The emperor not only preferred the picture to the money, but had it fixed up in his own chamber, where the Archigallus was also preserved, and which was valued at [illegible] (about 530*l.*). These productions entitle Parrhasius to the epithet of Pornographus, and prove that this style of painting was in fashion long before the [illegible] of Tiberius.

Plutarch instances Parrhasius's picture of Ulysses feigning insanity as an improper subject for the pencil, yet commended to our taste through the spirit of the conception and the truth of the execution. (*De Aud. Poet.*)

Parrhasius painted a Hercules, which he affirmed was a facsimile of the god as he had frequently appeared to him in his dreams. (Athenæus, xii. 543.) He painted also a Philoctetes. (*Anthol. Gr.*, iv. 8, 23.) Pliny mentions a contest between Parrhasius and Timanthes of Cythnus, in which the former was beaten: the subject of the picture was the contest of Ulysses and Ajax. The proud painter, indignant at the decision of the judges, is said to have remarked, that the unfortunate son of Telamon was for a second time, in the same cause, defeated by an unworthy rival. (Athen., xii. 543.)

Pliny records also a trial of skill between Parrhasius and Zeuxis, in which the latter allowed his grapes to have been surpassed by the drapery of the former: this contest, says Fuseli, 'if not a fable, was an effort of puerile dexterity.'

The story told by Seneca of Parrhasius having crucified an old Olynthian captive when about to paint a Prometheus chained, that he might see from nature the true expression of bodily agony, cannot relate to this Parrhasius, and is probably a fiction: it is nowhere to be found but in the 'Controversiæ' (v. 10) of the preceptor of Nero. Olynthus was taken by Philip in the second year of the 108th Olympiad, or B.C. 347, which is nearly half a century later than the latest accounts we have of Parrhasius. Socrates died in the 95th Olympiad, and Parrhasius must therefore have been already celebrated before that time, from his dialogue with that philosopher upon the principles of art as preserved by Xenophon. (*Mem.*, iii. 10.) He is even mentioned by Pausanias (i. 28) in the 84th Olympiad, when he is said to have painted a battle of the Lapithæ and Centaurs on the shield of the Minerva of Phidias at Athens: supposing such to be the case (for although improbable, it is still not impossible), Parrhasius, if living, must have been at least 120 years of age when Philip took Olynthus. A similar story is told of Giotto, with probably as much truth; and some have also said the same of Michael Angelo Buonarotti.

PARROT. [PSITTACIDÆ.]

PARSEES. [PERSIA.]

PARSLEY. The garden parsley (*Petroselinum sativum*) is a hardy biennial, a native of Sardinia, introduced into this country about the middle of the sixteenth century. There are three varieties, two of which are well known, and commonly used as pot-herbs, and for garnishing, namely: the common or *plain-leaved*; the *curled*; and the *Hamburg, large* or *carrot-rooted*, which last is cultivated only for its roots, occasionally used as young carrots. The curled variety is by far the most useful, and from its beautiful curled foliage it cannot be mistaken for the *Æthusa Cynapium*, or fool's parsley, a poisonous plant somewhat resembling the plain-leaved parsley. [ÆTHUSA.]

The cultivation is simply that of sowing, usually in spring, in shallow drills about a foot apart; or in single rows along the borders of a kitchen-garden. The Hamburg requires to be sown in tolerably light soil, such as would suit the carrot, like which it requires in all respects to be treated.

PARSNIP. The cultivated parsnip (*Pastinaca sativa*) is a native of England, and ranks amongst the hardiest of kitchen-garden productions, as is proved by the fact of its having withstood the intense frost of 1838, in the open ground. There are four varieties, namely, the *Common*, *Guernsey*, *Hollow-crowned*, and *Round* or *Turnip-rooted*. The Hollow-crowned has been found the best. The mode of culture is very simple. The soil ought to be deep and rather light, but by no means adhesive; and it should be trenched to the depth of at least two feet. In order that the roots may be clean and sound, fresh manure should not be applied; indeed if the soil be in tolerably good condition, no manure is required; and on the contrary, if it be poor, a more liberal supply should be given in the previous season, so that any immediate application along with the parsnip crop is not requisite.

The seed should be sown in March, and as early in that month as the weather and state of the soil will permit, in shallow drills eighteen inches apart, the plants being afterwards thinned to about a foot asunder in the rows. The roots are not in perfection for culinary purposes till their first season's growth is completed, which is indicated by the decay of the greater part of the leaves.

Some may be then taken up, their tops cut off, but not [illegible] closely, and the roots stored in sand in a cool place, so as to guard against the stimuli of light and heat as much as possible. This precaution of storing in the early part of winter is only necessary in case of frost becoming so severe as to render the operation of removal difficult: but the whole of the crop should be taken out of the ground before vegetation recommences in the spring, and treated as above.

Besides the use of the roots for the kitchen, a wine is sometimes prepared from them. Abounding in saccharine matter, they afford by distillation an ardent spirit, the process of fermentation being facilitated by the addition of a small portion of malt liquor.

PARSON. [Benefice, p. 219.]

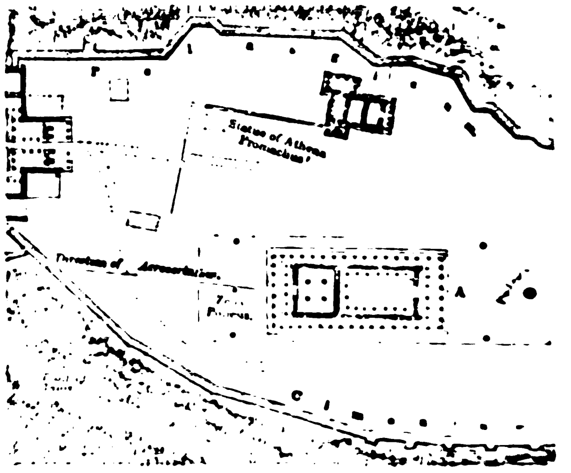
PARTHENAY. [Sevres.]

PARTHE'NIUS, the antient name of the Bartan or Bartin. This river rises in Mount Olgassys, which is a continuation of the mountain-chain which runs from Mysia towards Armenia, and is known by the names of Ida, Olympus, &c. It flows in a north-westerly direction into the Euxine, and separates Bithynia and Paphlagonia. The country through which it flows is very fertile and beautiful. (Strabo, xii. 543; Tournefort, vol. ii., p. 88.) Ovid (*Ex Ponto*, iv. 10, l. 49) and Ammianus Marcellinus (xxii. 8) speak of the Parthenius as a rapid stream; and Xenophon (*Anab.*, v. 6, s. 9) says that it is impassable. It is mentioned in the Iliad (ii. 854).

The etymology of the name is differently explained. The Greek writers connect it with the Greek word *parthenos*, 'a virgin,' and for the most part suppose that it derived its name from Artemis being accustomed to bathe in its waters. (Apoll., *Argon.*, ii. 938.) Strabo (xii., p. 543) supposes that it was so called on account of the fertile country through which it flows; but the name was probably a native word, and had no connection with the Greek *parthenos*, except an accidental similarity of sound. Some modern writers imagine that it may be connected with the Hebrew-Phœnician *phorath*, which means fruitful. The antient name is still preserved by the Greeks, who call it Bartin, or Bartan, but it is called Dolap by the Turks.

PAR'THENON (Παρθενών), the temple of the virgin goddess Athene, or Minerva, the protectress of Athens, is situated on the Acropolis of that city. This edifice was erected in the time of Pericles (about B.C. 448). The architects were Callicrates and Ictinus, and the sculptures were executed by Phidias and his assistants. This temple has always been considered the most refined example of the Grecian Doric style, and one of the noblest monuments of antiquity. Yet its grandeur was by no means owing to its extraordinary dimensions, since in point of size it falls very short of many other structures, modern* as well as antient, its extreme length being only 228 feet, and its breadth 100, and the interior of the cella only 145 ft. 6 in. by 63 ft. 6 in., which is little more as to length than the size of the Elgin Hall in the British Museum, viz. 143 by 46 feet. Technically described, this temple was peripteral octastyle, that is, it had columns along its sides and at both ends, viz. eight beneath each pediment, making in all 46 columns, there being, including those at the angles, 17 on each side, or 16 intercolumns. Besides these external columns, there was likewise a range of inner columns at each end, forming the pronaos and opisthodomus, namely six, not however placed *in antis*, as usually, but the extreme columns in front of the antæ extending from the walls of the cella. The cella itself was hypæthral, that is, the central space between the columns along each side was open to the sky. This portion of the structure however was so shattered by an explosion in 16[illegible], when it was used as a powder-magazine by the Turks, at the time of the city being besieged by the Venetians, that its original design is now altogether matter of conjecture; besides which, the interior of the temple had been more or less injured by having been converted first into a Christian church, and afterwards into a Turkish mosque. Still, even in its present shattered and mangled state, it is the admiration of all travellers and artists who have beheld it, and some of whom have spoken of it in terms of enthusiasm that appear quite exaggerated. It is said that what now remains of it far exceeds any idea that can be derived from descriptions or drawings, and that it appears to be upon a much larger scale than it really is. In its original state indeed the effect must have been exceedingly impressive and fine; taking the building by itself, without reference to advantages of site, locality, climate, &c., it was distinguished by beauty of material, exquisiteness of execution, and grandeur of style; while to these architectural merits must be added the extraordinarily rich display of sculpture in the pediments, the metopes, and the frieze along the exterior of the cella, and also the decoration of painting [Polychromy], and of bronze ornaments. The chief portion of the sculpture of the edifice was removed by Lord Elgin. [Elgin Marbles.] This circumstance called forth at the time severe animadversion, though it is now well known that there was imminent danger of those relics of art being utterly destroyed by the wanton barbarism of the Turks and others. One object of art that originally decorated the interior or shrine was the chryselephantine statue of Minerva, 39 feet high, which was the work of Phidias. This figure was ornamented with gold, to the amount of 40 talents according to Thucydides, but according to Philochorus, 44 talents, or about 120,000l. sterling; of which however it was stripped by Lachares, somewhat more than a century and a quarter after the death of Pericles.

The Parthenon.



Plan of a portion of the Acropolis. A, the Parthenon.

Since the establishment of King Otho's government, 1833, excavations have been made on the Acropolis and around the Parthenon, and a great number of fragments of sculpture and architecture have been brought to light. Some of the fallen columns have also been replaced, and measures taken to restore the structure as far as circumstances will permit. For particulars as to the order and dimensions, see Column, page 3[illegible]5, and table, page 3[illegible]7.

In 1823, an edifice was begun on the Calton Hill, Edinburgh, which was, externally at least, to have been an exact model of the Parthenon, but after fourteen columns were put up, it was discontinued, nor is there any prospect of its being ever completed.

---

* For the dimensions of the Madeleine, which is externally a peripteral Greek temple, see Paris, page 287.

PARTHENOPE (Zoology). [PARTHENOPIANS.]

PARTHENO'PIANS. This tribe, in the arrangement of M. Milne Edwards, corresponds nearly to the genus *Parthenope* as established by Fabricius; but the species are separated by M. Edwards into the genera *Eumedonus, Eurynome, Lambrus, Parthenope,* and *Cryptopodia,* forming a natural group which, in the opinion of the last-named zoologist, establishes the passage between the *Maians* [MAIIDÆ] and the *Cyclometopes.*

Characters of the Tribe.—Carapace ordinarily triangular and hardly longer than it is wide; its latero-posterior borders in general nearly transverse, and the latero-anterior borders following the same direction as the edges of the rostrum; but the lateral spaces of the carapace are sometimes rounded, and its surface is nearly always lumpy and tuberculous. *Rostrum* in general small and entire, or only notched at the end; the *eyes* are nearly always perfectly retractile; the basilary joint of the *external antennæ* sometimes presents the same disposition as in the *Maians,* but in the great majority of cases it is quite otherwise; it is short, and is not joined to the neighbouring parts of the shell; its internal border does not concur to form the lower orbital wall, and its extremity does not reach to the front; the moveable stem of these antennæ is short, and takes its origin in a gap of the internal orbital angle. The *epistome* is much wider than it is long, and the form of the *external jaw-feet* is nearly the same as in the *Maians.* The anterior *feet* are very much developed, and widen so as nearly to make a right angle with the body; in the male they are always more than twice as long as the post-frontal portion of the carapace, and sometimes four times as long; the hand is nearly always triangular, and the claw suddenly curved downwards, so that its axis forms a very marked angle with that of the hand. The succeeding feet are, on the contrary, short; the second pair in general are less than once and a half of the length of the post-frontal portion of the carapace, and the others progressively diminish. The *abdomen* in the male presents considerable differences in the number of distinct joints, whilst in the female there are always seven.

Geographical Distribution.—The tribe is widely distributed, and species are found in the English Channel, the Mediterranean Sea, and the Indian Ocean.

Place in the System.—The Parthenopians are placed by M. Milne Edwards between the *Maians* and the *Cyclometopes.*

Eumedonus. (Edwards.)

This genus, in the opinion of the last-named author, establishes in some sort the passage between the *Stenorhynchi* and the *Achæi* on one side, and *Eurynome, Lambrus,* and *Parthenope,* on the other.

Generic Character.—Carapace nearly pentagonal, as in *Parthenope,* but it scarcely ever goes beyond the level of the third pair of feet. *Body* depressed; *rostrum* very wide and very much advanced, and divided at its extremity only; *eyes* very short, their peduncle entirely filling the orbits, which are circular, a character which again approximates this genus to the Stenorhynchi; internal *antennæ* bent back very obliquely outwards; external antennæ but little developed; their first joint does not distinctly concur in the formation of the lower wall of the orbit; their moveable stem arises in the slit which the two internal angles of that cavity leave between them nearly as in the Parthenopes, and their terminal joint is very short. The *epistome* is shorter than in most of the *Oxyrhynchi.* The *external jaw-feet* present nothing remarkable. In the male the first pair of thoracic feet are stout and much longer than the succeeding ones; all these last are a little compressed; and their third joint is surmounted by a crest which is not distinctly visible on their other joints. The second pair of feet are rather shorter than the third and fifth, which are nearly as long as the fourth; instead of being placed on the same level, they are inserted above so as partially to cover them. The *abdomen* of the male is composed of seven joints, the two first of which are visible on the dorsal surface of the body. Abdomen of the female unknown to M. Edwards.

Example, *Eumedonus niger.*

Description.—This small and only known species is remarkable for the great prolongation on each side of the carapace: these points are directed outwards, and their base occupies the whole of the hepatic region. There are some depressions on the upper surface of the carapace, which is, like all the rest of the body, covered by small miliary granulations. The rostrum is very wide, flat, slightly notched at the end, and about one-third of the length of the entire carapace. The anterior feet are armed with a strong spine which occupies the lower border of the carpus, and two small points placed on the upper border of the hand, which is slightly tumid. The pincers are armed with some rounded teeth, and are not sensibly curved inwards. The other feet are slightly hairy. Colour brownish black.

Locality.—Coasts of China.

Eumedonus niger.

Eurynome. (Leach.)

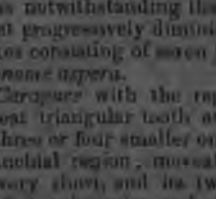
This genus, in the opinion of M. Edwards, establishes the passage between the *Lambri* and the other Oxyrhynchi. The general form of the body and its aspect approximate these crustaceans to *Parthenope,* whilst the disposition of their external antennæ is similar to what is seen in *Maia.*

Generic Character.—Carapace nearly triangular, with a rounded base, very much embossed and covered with asperities. *Rostrum* horizontal and divided into two triangular horns. *Eyes* small; *orbits* deep, their upper border very projecting and separated from the external angle by a slit. The internal *antennæ* bent back longitudinally; the first joint of the external ones terminating at the internal angle of the orbit and supporting the succeeding joint at the upper edge of its extremity, so that the moveable stem of these antennæ, which is prolonged under the *rostrum,* appears to spring from the internal canthus of the eyes. *Epistome* nearly square, and third joint of the *external jaw-feet* much dilated outwards. *Sternal plastron* nearly oval, and its median suture occupying the two last thoracic rings. First pair of feet hardly larger than the succeeding ones, rather long in the male, whilst in the female they are very short, but less notwithstanding than the second pair; the succeeding feet progressively diminish in length. *Abdomen* in both sexes consisting of seven joints.

Example, *Eurynome aspera.*

Description.—Carapace with the regions very distinct, rugose, with a great triangular tooth at the external angle of the orbit, and three or four smaller ones along the lateral border on the branchial region; moveable stem of the external antennæ very short, and its two first joints very small. Anterior feet tuberculous and slightly compressed, nearly straight in the female and with the pincer curved inwards in the male; succeeding feet rugose, and furnished with a crest, which is most marked on the third joint. Length about half an inch. Colour rosy, with bluish tints.

Locality.—The coasts of Noirmoutier and of the British Channel, at rather considerable depths.



Eurynome aspera.

M. Milne Edwards refers to the *Eurynome (Lissa) verrucosa* (?) of M. Risso, from the Mediterranean, as having much in common with the species above noticed; but the details are not, in his opinion, sufficient to enable us either to refer it with certainty to this genus or to distinguish it from *Eurynome rugosa.*

Lambrus. (Leach.)

Carapace nearly as long as it is wide, rounded on the sides and narrowed forwards; branchial regions very much developed, tumid, and separated from the median portion of the carapace by a deep furrow; stomachal region, on the contrary, very narrow; upper surface of the edge of the shell always more or less tuberculous or spiny. *Rostrum* small but rather advanced. *Eyes* perfectly retractile and orbits nearly circular, the walls of these cavities presenting a fissure above and a wide and deep gap below the internal canthus of the eye. The *internal antennæ* bend back obliquely, and the fossets which lodge them are in general continuous with the orbits, for the space which separates the internal angle of the lower orbital border from the front is far from being filled by the peduncle of the *external antennæ*, whose first joint is extremely small and scarcely longer than it is wide; the second is more elongated, but never reaches to the front, and advances between the basilary joint of the internal antennæ and the internal border of the lower wall of the orbit; the third joint has its origin in the gap which occupies the internal angle of this cavity; and the fourth or terminal filament is very short. The *epistome* is but little developed and much wider than it is long; the pterygostomian regions are small and nearly triangular. The external *jaw-feet* present nothing remarkable. The *sternal plastron* is much longer than it is wide. The first pair of feet are at least twice and a half as long as the post-frontal portion of the carapace, and often are twice that length; they extend to the right angle of each side of the body, do not differ sensibly from each other, and are always more or less triangular; the claw which terminates them is small and suddenly curved downwards and inwards, so as to form an angle with the rest of the hand. The succeeding feet are short and slender; their length diminishes progressively, and the second pair are never more than half as long as the first. The *abdomen* of the female presents nothing remarkable, but sometimes there are six instead of seven joints: in the male, the third, fourth, and fifth rings are more or less intimately blended, so that this part of the body is only composed of five distinct joints, and sometimes there are but four.

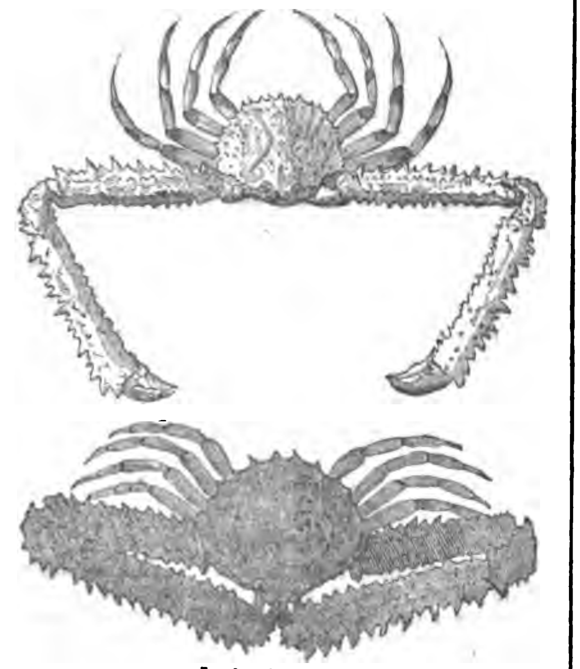
Geographical Distribution of the Genus.—The Mediterranean Sea and Indian Ocean, where the species live among the rocks at considerable depths.

§ A. Carapace nearly as long as it is wide.

a. Carapace rugose, covered above with spines or tubercles.

*a.** Four first pair of feet having the third joint armed with spines.

Example, *Lambrus longimanus.*



Lambrus longimauus.

Description.—Rostrum extremely small, scarcely projecting, horizontal, and formed of three teeth. Carapace nearly ular, furnished above with simple spines and tubercles; al edges armed with very long and slightly ramose s; hands triangular, nearly smooth on the upper sur- rough with branched spines on the upper border, and with large pointed teeth, and dentilated edges on the external border. There are some very short spines on the upper and lower borders of the third joint of the four last pair of feet. Length about one inch.

Locality.—Pondicherry, Amboyna, &c.

*a.*** Four last pair of feet without spines.

Example, *Lambrus angulifrons.* Length nearly an inch.

Locality.—Gulf of Naples and coasts of Sicily.

a.a. Carapace nearly quite smooth above.

Example, *Lambrus Messana.* Length about an inch. Colour red-brown.

Locality.—The volcanic rocks of the coasts of Sicily.

§ B. Carapace much wider than it is long.

b. Upper surface of the hands rough with spines, which are more or less ramose, and having their upper and internal borders armed with spines like each other, and neither compressed nor united into a crest.

Example, *Lambrus echinatus.* Body covered with a brown down. Length about 18 lines.

Locality.—The coast of Pondicherry.

b.b. Upper surface of the hands more or less smooth, and never with ramose spines; their upper and external borders armed with teeth, which are compressed, and so disposed as to form a crest.

Example, *Lambrus serratus.* Length nearly an inch.

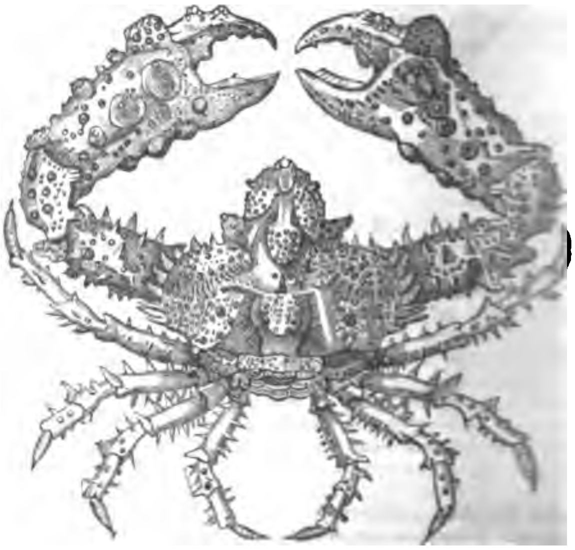
Locality.—Indian Ocean.

Parthenope.

This genus, as limited by modern authors, consists but of one species, distinguished principally by the disposition of the *external antennæ*, whose basilary joint is not soldered to the neighbouring parts, but nearly reaches the front, and whose second joint, more than half as short as the first, is lodged in the gap of the lower orbital angle; the smallness of this gap, which makes the orbit communicate with the antennary fosset; the regularly triangular form of the *carapace;* and the existence of seven distinct joints in the abdomen of both sexes.

Example, *Parthenope horrida.* Carapace pentagonal, wider than it is long, horizontal, strongly embossed, and tuberculous above; rostrum short, triangular, and armed below with a strong interantennary tooth; orbits circular, with a fissure on the upper border; latero-anterior borders of the carapace very oblique, and armed with spines; anterior feet very large, of unequal size, and covered with large spiniferous tubercles; claws less compressed and less inflected than in *Lambrus.* The four succeeding pair of feet armed to the origin of the tarsus with sharp and very large spines, forming one row above and two below.

Locality.—Indian and Atlantic oceans.



Parthenope horrida.

Cryptopodia. (Edwards.)

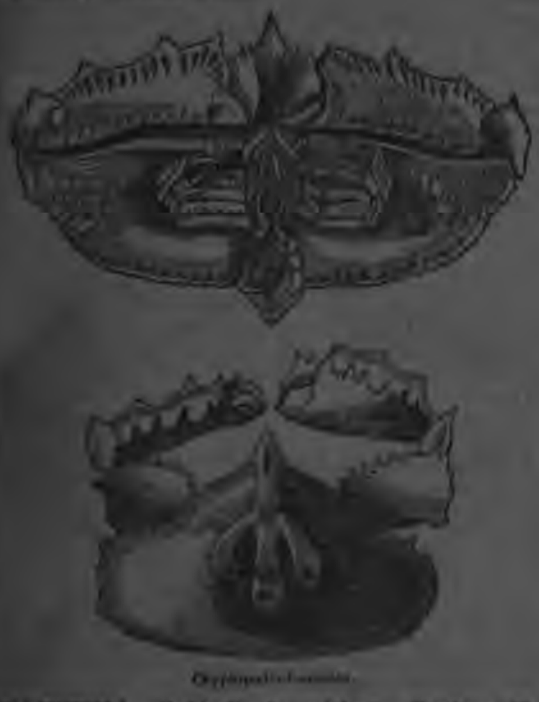
M. Milne Edwards is of opinion that this singular genus establishes in some respects the passage from *Lambrus* to *Œthra* [Œthra]; and, in fact, he observes, the form of its feet is the same as in the first; while the carapace presents, as in the last, lateral expansions which extend above [illegible] and hide them. Edwards therefore placed *Cryptopodia* among his *Parthenopes*, Lamarck among the *Æthræ*, and Bosc both among the *Calappæ* and *Maiæ*.

Generic Character.—*Carapace* slightly tumid, and in the form of a triangle, which is very wide, very short, and rounded at the base; it is nearly twice as wide as it is long, but this great width does not depend on that of the body itself, but is due to the existence of the lamellar prolongation which surrounds the three posterior fourths of the dorsal buckler (shield). This prolongation extends very far beyond the insertion of the abdomen; but it is especially considerable on the lateral parts, for there it forms an enormous vault on each side, which completely hides the four last pairs of feet. *Front* triangular, horizontal, and rather advanced. *Eyes* very small and completely retractile. *Internal antennæ* like those of *Æthra*; their first joint quadrilateral and flat; the second rather longer, and reaching to the front; the third lodged nearly entirely in the slit which exists between the front and the internal angle of the lower orbital border; the terminal stem which thus springs from the internal canthus of the eyes is very short. *Epistome* rather wider than it is long; the second joint of the *external jaw-feet* terminating anteriorly by a nearly straight border; and the third, which is square, presenting forwards a notch which occupies its internal border rather than its internal and anterior angle, and which gives insertion to the succeeding joint. *Sternal plastron* much longer than it is wide. *First pair of feet* very large and nearly prismatic; their direction and form nearly the same as in *Lambrus*. Four last pairs very small, and nearly of the same length; they scarcely reach beyond the vault which covers them. The *abdomen* in the female consists of seven joints.

Example, *Cryptopodia fornicata*.

Description.—Carapace smooth above and denticulated on the borders; rostrum entire, as long as it is wide; anterior feet about once and a half as long as the carapace; their third joint very much dilated posteriorly, and armed with spines on the anterior border. Four last pairs of feet furnished above and below with a denticulated crest for nearly the whole length of their third joint.

Locality.—Indian Ocean.



Cryptopodia fornicata.

PARTHIA, called by Strabo and Arrian, Parthyæa (Παρθυαία). This term originally comprised a small and mountainous country (Strabo, xi., p. 514) south-east of the Caspian sea, between Hyrcania and Aria; but the name was sometimes applied to the countries included in the later Parthian empire. It is difficult to define the boundaries of Parthia Proper, as they differed at various times. In the time of Strabo (xi. 514) Parthia extended on the west as far as Rhagæ and the Tapuri to the Caspian gates, and included the districts of Komisene (Kumis) and Chorene (Khuar). Pliny (vi. 29) says that it was bounded on the east by the Arii, on the south by the Carmani and Ariani, on the west by the Pratitæ Medi, and on the north by the Hyrcani.

The chief town of Parthia, and the only one in the country of any importance, was Hecatompylon, which, according to Strabo (xi. 514), was 1260 stadia from the Caspian gates. Quintus Curtius (vi. 2) says that it was founded by the Greeks; but the name, which is evidently Greek, is probably only a translation of a native word. The site of it is doubtful. Some writers identify it with the modern Damghan.

The Parthians were apparently of Scythian origin. According to Justin (xli. 1) their name signified in the Scythian language 'banished' or 'exiles.' The Parthians were subject to the Persian monarchy, and formed a satrapy together with the Chorasmii, Sogdi, and Arii. (Herod., iii. 93.) In the army of Xerxes they marched together with the Chorasmii, Sogdi, Gandarii, and Dadicæ (Herod., vii. 67); and in that of the last Darius they were united with the Hyrcanii and Tapuri under one commander. (Arrian, iii. 8.) Under Alexander, Parthia and Hyrcania together formed a satrapy (iii. 22), which also appears to have been the case under the Syrian kings.

On the death of Alexander, the Parthians espoused the side of Eumenes, and afterwards became subject successively to Antigonus and the Seleucidæ, till about B.C. 256, when they threw off the authority of the Syrian kings and were formed into an independent kingdom under the rule of Arsaces I. [ARSACES], from whom the succeeding kings received the title of Arsacidæ. His reign was the beginning of that great Parthian empire, which was gradually increased at the expense of the Syrian kingdom in the west and the Bactrian in the east; and at length extended from the Euphrates to the Indus, and from the Oxus to the Persian Gulf. In the time of Pliny (vi. 29) it was divided into 18 satrapies. The government was monarchical, but the kings were elected from the house of the Arsacidæ, and do not appear to have succeeded to the throne according to any acknowledged principle, and we thus constantly read of pretenders to the throne. Strabo says (xi. 515) that there were two supreme councils, one consisting of kindred, by which he probably means the family of the Arsacidæ; and the other of wise men and magi, from both of which the kings were chosen.

The Parthian empire lasted from B.C. 256 to A.D. 226. Its history may be divided into three periods:—

First Period, from B.C. 256 *to* B.C. 130.—During this period the Parthians were engaged in almost continual struggles with the Syrian kings. Under Mithridates I., the fifth or sixth in succession from Arsaces I., the dominions of the Parthian kings were extended as far as the Euphrates and the Indus; and Demetrius II., king of Syria, was defeated and taken prisoner about B.C. 140. Mithridates was succeeded by Phraates II., whose dominions were invaded by Antiochus Sidetes, the brother and successor of Demetrius. Antiochus met with considerable success at first, and defeated several armies of Phraates; but he was afterwards cut off with his whole army, about B.C. 130, and Parthia was from this time entirely delivered from the attacks of the Syrian kings. (Joseph., xiii. 8; Appian, *Syr.*, c. 68.)

Second Period, from B.C. 130-53.—During the early part of this period the Parthians were constantly engaged in wars with the nomade tribes of central Asia, who, after the destruction of the Greek kingdom in Bactria, attempted to obtain possession of the western parts of Asia. Phraates II. and his successor Artabanus fell in battle against these invaders; but their farther progress was effectually stopped by Mithridates II. (B.C. 124-87), who met however with a powerful rival in Tigranes, king of Armenia. Tigranes obtained possession of some of the western provinces of the Parthian empire; but after his conquest by the Romans, at the end of the Mithridatic war, the Parthians again acquired their former power, and were brought into immediate contact with the Romans.

Third Period, from B.C. 53 *to* A.D. 226, comprising the wars with the Romans. The invasion of Crassus during the reign of Orodes terminated in the death of the Roman general and the destruction of his army, B.C. 53. [CRASSUS.] In consequence of this victory the Parthians obtained a great increase of power. They invaded Syria in the following year, but were driven back by Cassius, the proconsul of the province, much to the relief of Cicero, who was at that time governor of the neighbouring province of Cilicia, and who appears from his letters to Atticus to have been very uneasy at the approach of the Parthians. In the war between Cæsar and Pompey, they took the side of Pompey; and after the death of Cæsar, they sided with Brutus and Cassius. Orodes, at the instigation of Labienus, the son of the Labienus who was Cæsar's lieutenant-general in Gaul, sent an army into Syria (B.C. 49), commanded by Pacorus and Labienus (Dion Cass., xlviii. 24; Vell., ii. 78); but they were defeated in the following year by Ventidius, the lieutenant of Antony (Dion Cass., xlviii. 39-41; Liv., *Ep.*, 127; Plut., *Ant.*, c. 33), and again in B.C. 38 (Dion Cass., xlix. 19, 20; Plut., *Ant.*, 34; Liv., *Ep.*, 138).

In B.C. 37, Orodes was murdered by his son Phraates IV., an ambitious and energetic prince, who, as soon as he obtained the throne, made great preparations for renewing the war with the Romans. To prevent the invasion of Syria again, Antony marched into Media against him, but was obliged to retire with great loss, B.C. 36 (Dion Cass., xlix. 25-31; Plut., *Ant.*, 37-51). Phraates however was unable to follow up his victory in consequence of having to contend with Tiridates, a formidable competitor for the Parthian throne. After an obstinate struggle, Tiridates was defeated, B.C. 25; but he contrived to get into his power the youngest son of Phraates, with whom he fled to Rome, and besought the assistance of Augustus. Menaced by a Roman invasion, and in danger from a large party of his own subjects, Phraates willingly made great concessions to Augustus. He sent four of his sons to Rome as hostages (Strabo, vi., p. 288; Tac., *Ann.*, ii. 1), and restored to Augustus (B.C. 29) the Roman standards which had been taken on the defeat of Crassus (Dion Cass., liv. 8; Suet., *Aug.*, 22), an event which is frequently alluded to by the poets of the Augustan age. A dispute subsequently arose (A.D. 2) between Augustus and Phraates respecting the kingdom of Armenia, on which account Caius Cæsar, the son of Agrippa, was sent into Asia with an army; but no hostilities ensued, in consequence of the submission of the Parthian king.

Phraates was assassinated A.D. 4, but his successor was also put to death after a reign of two years; and for several subsequent years Parthia was distracted by civil wars. In A.D. 16, Vonones, the eldest son of Phraates, who had been educated at Rome, was invited by the great body of the nation to occupy the throne; but his foreign education and Roman habits soon rendered him unpopular with his subjects (Tac., *Ann.*, ii. 2), and he was driven from the throne by Artabanus, a member of the family of the Arsacidæ (Tac., *Ann.*, ii. 3). In consequence of these troubles, Germanicus was sent into Asia, and concluded a peace with Artabanus. During the latter part of his reign, Artabanus was involved in hostilities with the Romans, and in contests with different competitors for the throne (Tac., *Ann.*, vi. 31-37). On the death of Artabanus, a civil war was again waged between his two sons for the succession to the throne, which ended in the victory of Bardanes (Tac., *Ann.*, xi. 9). On his death, A.D. 47, he was succeeded by his elder brother Gotarzes, to whom Claudius unsuccessfully opposed Meherdates, who had been educated at Rome (Tac., *Ann.*, xii. 10-14).

The numerous civil wars and the frequent revolt of the satraps had greatly weakened the power of the Parthians. The succession to the throne being uncertain, it was the great object of the Roman policy to support as much as possible pretenders to the throne, and thereby to weaken the kingdom by civil wars and to prevent all offensive operations on the part of the Parthians. The great subject of contention between the Romans and Parthians was the kingdom of Armenia, which had kings of its own, and was nominally independent, but its rulers were always appointed either by the Parthians or the Romans, and the attempts of each nation to place its own dependents on the throne led to almost incessant wars between them. Thus in the reign of Nero, the Parthians appointed Tiridates king of Armenia, and the Romans Tigranes, a descendant of Herod the Great; which dispute occasioned a war between the two nations, in which Corbulo invaded Armenia and obtained great success (Tac., *Ann.*, xiv. 24, 25). A similar dispute in the reign of Trajan occasioned a war between the Romans and Parthians, hich Armenia and Mesopotamia were converted into an provinces, and a new king of the Parthians appointed rajan (A.D. 114-116). During the reign of Hadrian however the conquered territory was given up, and the Euphrates again became the boundary of Parthia. The two nations remained at peace with one another till the reign of M. Aurelius and L. Verus. Cassius, the general of Verus, met with great success in the war, and at length took and almost destroyed the powerful city of Seleucia on the Tigris, A.D. 165. Under the reign of Vologeses IV., the Parthian dominions were invaded by Septimus Severus, who took Ctesiphon and several other important towns, A.D. 198, and annexed to the Roman empire the important province of Osrhoene. (Bayer, *Historia Osrhoene et Edessana.*) Caracalla followed up the successes of his father A.D. 217 [CARACALLA]; and though his successor Macrinus made a disgraceful peace with the Parthians, their power had been greatly weakened by the conquests of Verus, Severus, and Caracalla. Artaxerxes, who had served with great reputation in the army of Artabanus, the last king of Parthia, took advantage of the weakened state of the monarchy to found a new dynasty. He represented himself as a descendant of the antient kings of Persia, and called upon the Persians to recover their independence. This call was readily responded to; a large Persian army was collected; the Parthians were defeated in three great battles, and Artaxerxes succeeded to all the dominions of the Parthian kings, and became the founder of the new Persian empire, which is usually known by that of the Sassanidæ.

PARTICIPLE (in Grammar), the name of one of the parts of speech into which grammarians have distributed the words of a language. The word 'participle' comes from the Latin word 'participium,' which is formed on the same analogy as 'mancipium' and 'principium,' and means literally 'part-taking.' It is said, according to the old grammarians, to have obtained this name in consequence of its partaking of the nature both of the verb and the noun. Horne Tooke defines a participle to be a 'verb adjective,' which is perhaps as good a definition as can be given.

The English language has only two participles, which are usually called present and past. The present participle ends in *ing*, but it originally ended in *and*, which is the same termination as occurs in the cognate languages, namely *ant* in the Sanskrit; *ont* in the Greek, as *τύπτ-οντ-ος*; *ent* in the Latin, as *reg-ent-is*; and *end* in the German, as *lieb-end*. The term *present* participle is however not very correct, as it often denotes the continuation of an action or a state of being independent of the notion of time. This participle is called by some grammarians the *active* participle, but it is also passive; thus in the expression 'he was building the house,' the participle is active; but when we say 'the house was building,' it must be regarded as passive. In such sentences as the preceding there is no ambiguity, but when we say 'the man was killing,' the knowledge of the subject can alone enable us to determine whether the man was active or passive. This ambiguity in the use of the participle in *ing* has led to the modern practice, which is gaining ground, of expressing the notion of a passive participle by means of the present participle of the verb 'to be' and the past tense of the verb which is to be employed, as 'being loved,' 'being praised,' &c., which expressions are certainly very awkward and unwarranted by the usage of our best writers, if they are not absolutely wrong.

The other participle in English is used to denote past time, and is generally formed by adding *en* or *ed* and *d*, as *brok-en*, *praise-d*, &c.

PARTICLE, which is derived from a Latin word (*particula*) meaning a small part, is a term employed in grammar, but with rather an uncertain signification. Some of the grammarians included under this name all the parts of speech except the verb and the noun, namely, prepositions, adverbs, conjunctions, and interjections. Words of this class are included under the term of 'particles' by the Arabic grammarians. According to this definition, such words as 'vehementer,' 'unexpectedly,' &c. would be considered particles; which is certainly contrary to the common notion which we attach to a particle. In fact we seem to regard as particles all those small words which serve to make the sense of a proposition more clear and precise, though they might sometimes be omitted without rendering the meaning unintelligible. To this class of words belong the Greek γὲ, ἄρα, τοὶ, δὴ, νῦν, &c., the English *truly*, *now*, &c.

PARTITION. [PARCENERS.]

PARTITION TREATIES were two treaties concluded in the reign of William III. of England for regulating succession to the dominions of the crown of Spain, to each of which that king was a principal party. The war with France, which had lasted since May, 1689, having been put an end to by the several treaties of peace signed at Ryswick by France, England, Spain, and Holland, on the 20th of September, 1697, and by Germany on the 30th of October following, the apparently fast approaching death of Charles II., king of Spain, threatened to give rise to a new general war if the succession to his dominions should not be previously settled by agreement among the lately belligerent powers. Charles had no issue either by his first wife, Maria Louisa of France, who had died in 1689, or by his second, who still survived, the palatine princess Marianne of Neuburg, and no prospect of having any. Nor had he any brother. Of two sisters, the elder, Maria Theresa, married to Louis XIV. of France, had died in 1683, leaving a son, Louis, styled the Dauphin; the younger, Margarita Theresa, who died in 1673, had left by her husband, the emperor Leopold I., a daughter Maria Antonietta, married to Maximilian Emanuel, elector of Bavaria, and, she having also died in 1692, her heir was her son, the electoral prince Joseph Ferdinand. Maria Theresa however had on her marriage expressly renounced for herself and her posterity all claim of succession to the Spanish crown; and no doubt had ever been expressed as to the validity of that renunciation, either in France or in Spain. Maria Antonietta had also on her marriage made a similar renunciation; but her act had never been confirmed by the king or cortes of Spain, and in that country it was generally regarded as of no force. Her son, the electoral prince, therefore was commonly looked upon in Spain as the rightful heir of his grand-uncle; and this was also the view taken by Charles II. himself. It was not that however of the prince's grandfather, the emperor Leopold: it was he who, having pretensions of his own to the Spanish succession, had compelled his daughter to renounce her maternal inheritance; and those pretensions he now brought forward in opposition to those of his grandson. He claimed both as the true heir male of Ferdinand and Isabella, the founders of the Spanish monarchy, through a genealogy which we need not stop to trace; and more especially as the nearest male heir of Philip III. of Spain, the grandfather of Charles II., through his mother Maria, who was a daughter of Philip III. This explanation will make sufficiently intelligible the arrangements of the two Treaties of Partition.

The first was signed at the Hague, by the plenipotentiaries of England, France, and Holland, on the 11th of October, 1698. It provided, in substance, that in the event of the death of Charles II., the reigning king of Spain, without issue, the dauphin of France should have, in full satisfaction and extinction of his claims upon the Spanish succession, the kingdoms of Naples and Sicily, Sancto Stefano and the five other small islands on the coast of Sicily then held by Spain, the town and marquisate of Final, and the province of Guipuzcoa (with the exception of any places therein which might be found to lie beyond the Pyrenees); that to satisfy the claims of the emperor, the duchy of Milan should be made over to his second son, the archduke Charles; and that, with these exceptions, the crown of Spain, and all the kingdoms, islands, states, countries, and places then depending thereon, should be given and assigned to the prince, eldest son of the elector of Bavaria. In this way the share of the electoral prince, and the future extent of the Spanish dominion, was limited to Spain, the Netherlands, and America. It was intended that this arrangement, which was made with the greatest secrecy, should be kept a secret from the court of Madrid; but that court early obtained information of it (probably through the French king), the consequence of which was that Charles, in the indignation and unwonted vigour to which he was roused, made a will, naming the electoral prince of Bavaria his universal heir. Only a few weeks after this, in February, 1699, the electoral prince died, in his seventh year—poisoned, as his father did not hesitate to assert, by the contrivance of his own grandfather, the emperor. On this was arranged and concluded the Second Partition Treaty, between the same three, or rather two, powers which had been parties to the first, for William represented both England and the States-General of Holland. By this compact, which was signed at London, on the 3rd of March, 1700, the crown of Spain, with the territories formerly allotted to the electoral prince of Bavaria, was assigned to the archduke Charles of Austria; and the dauphin was to have the same share as before, with the addition of the duchies of Lorraine and Bar, which the duke of Lorraine was to be obliged to quit and exchange for the duchy of Milan. In his intrigues at the court of Madrid however Louis XIV. had consented to substitute for the dauphin and his heirs, the second son of that prince, Philip, duke of Anjou, if he could secure for him and his descendants the entire Spanish succession. At last, on the 2nd of October, this same year, the feeble and long-wavering Charles was prevailed upon to sign a will to that effect. He died on the 3rd of November following. The duke of Anjou was immediately declared by his grandfather king of Spain and the Indies, by the name of Philip V.; and the contest between him and Charles of Austria, or, as he called himself, Charles III. of Spain, occasioned the general war which was only terminated by the peace of Utrecht, in 1713.

PARTNERSHIP may be defined to be a contract between two or more persons for joining together their money, goods, labour, and skill, or any or all of them, upon an agreement that the gain or loss shall be divided between them; and its object must be some legal trade or transaction. The English law of partnership is founded on the common law, the so-called law of merchants, and the Roman law. By the common law a partner has no power to bind his co-partner by deed. By the law of merchants he has power to bind his co-partner by a bill of exchange, and there is no survivorship in the partnership stock. From the Roman law is derived the principle that a partnership is terminated by the death of a partner. (Gaius, iii. 152.)

If the judges have any doubt about the custom of merchants, they may send to them to know their custom, as they may send for the civilians to know their law; but the judges only recognise those customs of merchants that are general, not those that are particular usages.

We shall first speak of private unincorporated partnerships, to constitute which no writing is necessary. The acts of the parties, when there is no partnership contract in writing, are the evidence of the contract. Partners may be either ostensible, nominal, or dormant. He whose name appears to the world as a partner is an ostensible partner. An ostensible partner may or may not have an interest in the concern; if he has no interest in the concern, but allows his name to appear as one of the firm, he is a nominal partner; if his name and transactions as a partner are purposely concealed from the world, he is a dormant partner. But if his name and transactions are actually unknown to the world, he is more properly termed a secret partner. Generally speaking, any number of persons may be partners, but there are some exceptions, which are noticed under the head of 'Particular Partnerships.'

Any person of sound mind and not under any legal disability may be a partner. An infant may enter into this, as into any other trading contract which may possibly turn out to his advantage. It may however be avoided by him on coming of age, though the person with whom he contracts will be bound. An alien friend may be a trader and sue in personal actions, and may therefore be a partner. But an Englishman domiciled in a foreign country at war with England, or an alien enemy, cannot be a partner with a person in this country; at least he cannot sue in this country for a debt due to the firm. Married women are legally incapacitated from entering into the contract of partnership; and although they are sometimes, under positive covenants, entitled to shares in banking-houses and other mercantile concerns, yet in these cases their husbands are entitled to such shares, and become partners. If parties share in the profit and loss, they are partners, although one may bring into the trade money, another goods, and a third labour and skill, which was also the rule of the Roman law (Gaius, iii. 149); and where one party is sole owner of goods and another sole disposer or manager of them, if they share the profits, they are partners in those profits. Every man who has a share of the profits of a trade must also bear his share of the loss; for a right to a share of the profit legally implies a liability to bear a share of the loss. Yet it is not necessary to the partnership contract that every party should undertake to share the loss, for one may stipulate to be free from all liability to loss, and such stipulation will hold good as between himself and his co-contractors, which was also the rule of the Roman law, though he will still be liable to all those who have dealt with the firm of which he is a member. Persons who jointly purchase goods are not partners, unless they are jointly concerned in the profit or the produce arising from the sale of them. It is not necessary that the division of profit and loss among partners should be equal: it is sufficient that the parties share the profits, in order to render them partners. If they share the profits, they are by consequence bound to share the losses. But to constitute a man a partner on the ground of sharing profits, he must have an interest in the profits, as a principal in the firm; if he only receive a portion of the profits, by way of payment for his labour, trouble, or skill as a servant or agent of the concern, he is not a partner. Factors and brokers who receive a commission out of the profits of goods sold by them are not on that account partners with their principals; nor are persons who receive a certain share of the profits of an adventure, as payment in lieu of wages for acting as servants, partners in the adventure; nor even are persons who receive wages in proportion to the profits of the undertaking considered as partners. If a person lend money to a firm, and receives an annuity or interest, certain as to amount and duration, he is not a partner; but if he were to receive an annuity in lieu of the profits of the trade, and determinable on the event of the trade ceasing, it seems that he would be considered as a partner with the grantor of the annuity; or if he received an annuity varying in amount with the profits, he would be clearly a partner in the concern.

The contract of partnership must be formed for the purpose of some lawful trade, business, or adventure. If the subject of the contract be illegal, there can be no partnership founded upon it, so as to give the contractors a remedy against each other, or against third persons, at law or in equity; and if there be an illegal contract of partnership which is not executed, but executory only, none who are parties to it can by action or suit recover the money advanced for the purpose of establishing the partnership. A contract originally entered into for the purpose of evading the usury laws, and not *bonâ fide* with the view of partnership, cannot be supported as a legal contract: nor can a partnership between attorneys, where one of them is not duly qualified, be sustained. A partnership for importing prohibited goods, or making time bargains in the funds, would be held illegal and invalid, not less than a partnership for keeping a disorderly house, or robbing on the highway, or for acting plays within such distance from London as is forbidden by statute.

A person may stipulate not to be a partner, but if he shares the profit with those with whom he stipulates, he becomes a partner so far as relates to his liability to a third party. And if persons be known to share the profits of a trade, it is presumed that they are partners, and as such, liable to all who deal with the firm, whatever be the private agreement among themselves. But they may repel the presumption of partnership by showing that the legal relation of partnership among themselves does not exist. If a person allow his name to be used in a business, or in any other way consent to appear as a partner, he will be so considered with respect to other persons, whatever may be his agreement with the firm; and he will be equally responsible to third parties with the other partners, although he may not receive or be entitled to receive any of the profits. The ground of this rule of law is clear and reasonable: a person must be considered bound by a contract, if he act in such a way as to make other contracting parties believe that he is a party to the contract; and such is the case with a man who allows his name to appear as a member of a firm, as to all contracts and dealings which are necessary for carrying on the business of the firm.

A partnership at will is one which continues as long as the parties live and are able and willing to continue it: a partnership for a fixed term continues for the term if the parties live and are of legal capacity to continue it. A partnership at will may be dissolved at any time by the expressed will of any member of it, a rule which is derived from the Roman law, and which is a necessary consequence of the nature of the partnership contract. In such case the partnership is dissolved immediately upon notice given by any of the partners. The effect of such dissolution is to stop all new partnership dealings or contracts; but the partnership still continues for the purpose of completing all contracts already made, and all dealings or undertakings already commenced. On such dissolution, any partner is entitled to have the whole partnership stock, and the interest in the premises on which the business is carried on, converted into money, and to receive his share of the produce. In all cases, by the natural death of a partner, the partnership is dissolved, a rule also derived from the Roman law, as already stated: it is also dissolved by a partner's civil death, as his outlawry, or attainder for treason or felony; for an outlaw, being dead in law, incapable of entering into any contract, bringing any suit, or holding any property, a partnership in which he is engaged is therefore dissolved; and, strictly speaking, the whole property is forfeited to the crown; for as the king never becomes joint tenant, or tenant in common with the other partner, the crown takes the whole; but this right is seldom enforced against creditors or innocent partners. A marriage of a feme-sole trader is also a dissolution of a partnership at will. A partnership for a term may be dissolved before its expiration by the mutual consent of the parties, by the decree of a court of equity, or by the bankruptcy, outlawry, or felony of any of the partners. A court of equity will in some cases dissolve a partnership on the ground of incurable insanity in one of the partnership. A partner may agree that upon his death the business may be carried on beyond the legal period of dissolution in the hands of his children or other third parties, but this is properly an agreement for a new partnership. Partners cannot be relieved from future liabilities to third parties without notice to them and to the world in general that the partnership has ceased; but in the case of a dormant partner, if none of the creditors know that he is a partner, no notice of his retirement from the firm is necessary; and if it be known to some, notice to such only will be sufficient. On the death of a partner, notice of the dissolution to third parties is unnecessary.

Partners are joint tenants in the stock and all effects; yet there is no survivorship in equity, or, as it has been said, at law, in such part of the stock as is moveable. Upon the decease of a partner, his personal representatives become entitled to his share of the moveable stock and effects, and they thereupon become in equity, and, as it has been said, at law, tenants in common with the surviving partners. If, as is generally the case in the purchase of lands for the purposes of a partnership, they are conveyed to the partners as tenants in common, and one of the partners should die intestate, the legal estate in his share will descend to his heir, who will be tenant in common with the other partners. If the lands were conveyed to them as joint tenants, there will be no survivorship in equity; and it becomes then a question whether, upon the death of a joint trader, who, with his partners, has purchased lands for the purpose of the trade, *his share* will descend for the benefit of his heir or his next *of kin*; and the better opinion seems to be, although the point has never been decided, that although the legal estate in freehold property purchased by partners for the purposes of their trade will go in the ordinary course of descent, yet the equitable interest will be held to be part of the partnership stock, and distributable as personal estate. It is scarcely necessary to observe, that upon the purchase of lands, they may be expressly conveyed so as to be always held as real estate, and descend to the heirs of the several partners.

It sometimes happens that one person supplies goods for an adventure, and another only his time, trouble, and credit; yet if in the agreement between the parties there are words which imply a joint undertaking, these words are evidence of an intention to share jointly the goods and also the profits of them.

There is an implied obligation, in the absence of express stipulation, among partners to use the property for the benefit of all of them: and any fraud on the part of one partner, either by misapplication of the partnership fund or in any other way, is a matter of which a court of equity will take cognizance. No partner has a right to engage in any business or speculation which must necessarily deprive the partnership of his time, skill, and labour, because it is the duty of each to devote himself to the interest of the firm. It is the duty of each partner to keep precise accounts, and to have them always ready for the inspection of his co-partner. Each partner is liable to the performance of all contracts of his co-partners, in the same manner as if entered into personally by himself, provided they relate to matters which are within the objects and purposes of the partnership. If the parties to the contract of partnership do not regulate it by express stipulation amongst themselves, the contract, with its duties and obligations, will be implied and enforced by the rules of law applicable to persons in such relative situations; and where the contract does not reach all the duties and obligations, such omissions will be supplied by the same rules of law. Though partners may have entered into a written agreement which specified the terms on which the joint concern is to be carried on, yet, if there be such a course of dealing as leads to the conclusion that they have agreed to change the terms of the original written agreement, they will be considered to have done so. For instance, if the agreement be that no partner shall draw or accept a bill of exchange in his own name, without the concurrence of all the others, yet, if they afterwards adopt a practice of permitting one of them to draw or accept bills without the concurrence of the others, it will be held that they have so far varied the terms of the original agreement. The transactions of partners are always to be looked to in order to determine between them, even against the written articles, what clauses in those articles will not bind them. It is impossible to state all the varieties of stipulation which are introduced into partnership articles; it will be sufficient to repeat that within the limits before laid down, the parties may enter into such stipulations as they please.

One partner may maintain an action of covenant against his co-partner, whether the covenant be for the payment of money or the performance of any act for commencing or establishing the partnership, or for the performance of any of the articles after the partnership has commenced; and if adequate compensation for the breach cannot be had at law, a court of equity will enforce a specific performance of the covenant itself. Courts of law do not allow actions of debt by one partner against another for money due upon simple contract, as for money laid out by one partner for the purposes of the partnership. The partner who is aggrieved must therefore enforce his remedy by action of account, or by an application to a court of equity, by filing a bill for an account and a dissolution of the partnership. A partner cannot maintain an action of debt against his co-partner for work and labour performed, or money expended on account of the partnership; if therefore he has a claim upon his co-partner for a sum of money due on account of the partnership, but not constituting the balance of a separate account, or a general balance of all accounts, his only mode of recovering the amount is by an action of account, or by a bill in a court of equity praying for an account, and usually also for a dissolution. If it turn out that an undertaking is impracticable, as if a machine, for the working of which the partnership was entered into, will not answer the purposes intended, and so the object of the partners is frustrated, or if either party commit fraud, or gross acts of carelessness or waste in the administration of the partnership, the party aggrieved has a right to a dissolution, and the same will be decreed in equity. A partner is also entitled to an account of the partnership assets against his co-partner, but it was formerly held that he could not have it pending the partnership. If therefore he filed his bill for an account, it was also necessary to pray for a dissolution. It is now considered that a partner may have such an account on stating a proper case, without asking for a dissolution; but, considering the circumstances under which a partner files a bill for an account of partnership dealings, it will seldom happen that it will be his interest not to pray for a dissolution of the partnership. Where one partner has committed such breaches of duty as would warrant a decree for a dissolution, a court of equity will interfere summarily by injunction: as where one partner has involved the partnership in debt, or has himself become insolvent, the court will restrain him from drawing, accepting, or indorsing bills in the name of the firm, from receiving the partnership debts, and from continuing to carry on the business by entering into new contracts. It will also restrain an action brought by one partner against his co-partner on a separate and private account, upon payment by the latter of the money into court. So it will restrain the application of the partnership property to a use not warranted by the articles; or an execution against the partnership property for the separate debt of one partner. A court of equity will appoint a receiver where one partner excludes another from taking such part in the concern as he is entitled to take, and will do this even with a view to the continuance of the co-partnership, if it is for the benefit of the contracting partners, although such a step is usually taken with a view to a dissolution and winding up of the partnership affairs. Whether the party applying for a receiver wish a continuance or dissolution of the partnership, he must make out such a case to induce the court to interfere, as would authorise a decree for a dissolution.

Generally speaking one partner has an implied authority to bind the firm by contracts relating to the partnership, and he can do this by mere verbal or written agreements, or by negotiable securities, such as bills of exchange and promissory notes. One partner may pledge the credit of the firm to any amount; but there are some exceptions to this rule. A dormant partner is in all cases liable for the contracts of the firm during the time that he is actually a partner; and a nominal partner is in the same manner liable during the time that he holds himself out to the world as a partner. Partners can make no arrangements among themselves which will limit or prevent their ordinary responsibilities to third parties. The power of one partner, above alluded to, to bind his co-partner, is implied in law, no express authority from the latter being necessary for that purpose; and in the case of bills of exchange, it exists by custom which has been judicially recognised. One partner may give a guarantee for himself and his partners, and the firm will be bound by it, if it be made in a matter relating to the partnership. The act and assurance of one partner, made with reference to business transacted by the firm, will bind all the partners. A partner will also be liable in respect of a fraud committed by his co-partner, if committed in the capacity of partner, in contracts relating to the co-partnership, made with innocent third persons. Thus, if a partner purchase goods such as are used in the business, and fraudulently convert them to his own use, the innocent partner, provided there be no collusion between the seller and the buyer, is liable for the price of the articles. But partners are not liable for the wrongs of each other, excepting where one partner acts as the servant of the rest, in which case the whole of the partners are liable to the consequences of any wrong he may do; and they may be proceeded against altogether, or one may be sued alone for the whole of the damage done. One partner has no implied authority to bind his co-partner by deed, yet if he execute a deed on behalf of the firm, in the presence of and with the consent of his co-partners, it will bind the firm. It seems that a release by one of several partners to a debtor of the firm binds the firm; but if such release be fraudulent, it will be set aside by a court of equity; and even a court of law will interfere to prevent a fraudulent release from being pleaded.

Where no time is mentioned in the deed of partnership for its commencement, the liabilities of the firm will commence from the date of the deed; but in adventures, unless the parties have previously held themselves out as partners, the liabilities commence from the time fixed by the contract. An in-coming partner is not liable for debts contracted before he joined the firm, but if he pay any of the old debts or interest upon them, or does other special acts, he may render himself liable in equity. In an adventure an in-coming partner is not liable for the price of the goods. When an infant partner comes of age, and does not disaffirm the partnership, if he wish to avoid being liable for the future debts, he must give the creditors notice of his disaffirmance: but for the past contracts he cannot be sued unless he promise to pay, or his ratification of the debts contracted in infancy be made in writing. On the retirement of an ostensible partner, notice of his retirement must be given, or he will be liable to the creditors of the continuing firm for subsequent contracts made by them, and such notice is usually given in the Gazette; but notice in the Gazette will not bind creditors who are not shown to have seen the notice. Third persons have a claim against a dormant partner for contracts entered into by the firm while he was a partner. This claim is founded on such dormant partner being actually a partner; and therefore it is unnecessary, on the dissolution of a partnership between an ostensible and a dormant partner, to give notice of the dissolution to the creditors, in order to protect the latter from subsequent contracts; for when the dormant partner has ceased to be a partner, he is relieved from all future liability.

It is collected from the majority of cases that a partnership contract is joint (not joint and several) both at law and in equity. Upon the death of a partner therefore the legal remedy against him in respect to the joint contract is extinguished, and the creditor can maintain an action against the surviving partners only. But the rule of equity as applicable to partners with respect to third parties was considered to be that the joint debts should be satisfied out of the joint estate; if that were insufficient, then subject to the claims of their separate creditors out of their separate estates proportionally; and if any of them were insolvent, then out of the remaining separate estates proportionally. But the case of *Devaynes* v. *Noble* (1 Mer., 529), since affirmed on appeal by Lord Brougham (2 R. & M. 495), has established the principle that a partnership contract is several as well as joint; and that a partnership creditor may have recourse for full payment to the estate of a deceased partner. And the same judge (Sir W. Grant) who decided that case, declared that a partnership debt has been treated in equity as the several debt of each partner, though at law it is only the joint debt of all. By this decision it appears that a joint creditor on the death of one partner obtains a more advantageous remedy against his estate than he would have had against his separate estate if living. But it seems doubtful whether this point can be considered as finally settled.

It has been before said that notice of the decease of a partner to the creditors of the firm is not necessary to free his estate from future liability; but it is otherwise if one of the surviving partners be executor of the deceased. A deceased partner sometimes directs his executors to continue the trade; in that case his estate will be liable to the extent to which he directs his assets to be employed. If the executor exceed that limit, he becomes personally responsible.

In actions by partners, all the partners may, and all ostensible partners must, join as plaintiffs, unless the contract upon which the action is brought be in writing under seal, when only those partners who are included can sue thereon. But if a contract not under seal be made by some, for the benefit of themselves and others, those for whose benefit it is made, as well as those whose names appear on the contract, may sue. Parties to a legal partnership cannot recover upon an illegal contract, although its illegality, at the time it was made, were only known to one of the members of the firm. Persons who may legally be partners in foreign countries, as husband and wife, cannot sue here as partners, for by the law of England husband and wife are not permitted to sue as partners. On the other hand, partners trading abroad in such a manner as to make a partnership here, may sue as partners for consignments sent to this country, though they cannot sue as partners at the place of trading by reason of the particular law of that place. The construction of contracts is governed by the laws of the country in which they are made; but remedies must be pursued by the means pointed out by the law of the country whose tribunals are appealed to. The laws of the country where the contract was made can only have a reference to the nature of the contract, not to the mode of enforcing it. If partners have occasion to prefer an indictment relating to the partnership property, such property may be stated in the indictment as belonging to one of them by name, and to another or others, as the case may be. But though it is not necessary to name all the partners, yet where there are other partners, that fact should appear in the indictment, or the prisoner must be acquitted.

A whole firm may become bankrupt, or some or one only of the partners may become so, whilst the remaining members may be solvent; but those only of the partners who have committed acts of bankruptcy are to be deemed bankrupts; and to constitute two or more bankrupts under a single fiat, there must be evidence of joint trading. Upon the bankruptcy, the whole of the bankrupt's property vests absolutely in the assignees, who have the same remedy by action for the recovery of the debts due to the bankrupt, and for the redress of all civil injuries with respect to the property passing to them under the fiat, as the bankrupt would have had if no fiat had issued. Accordingly, when the bankruptcy is separate, the solvent partners join with the assignees in an action for the recovery of the joint debts. On the bankruptcy of one partner, the solvent partners become tenants in common with the assignees of all the partnership effects. Upon the bankruptcy of one partner, under a separate fiat issued against him, his assignees take all his separate property and all his interest in the joint property; and if a joint fiat issue against all, the assignees take all the joint property, and all the separate property of each individual partner. Joint estate is that in which the partners are jointly interested for the purposes of the partnership at the time of the bankruptcy. Separate estate is that in which the partners are each separately interested at that time. Joint debts are those for which an action, if brought, must be brought against all the partners constituting the firm; in all cases therefore when a partner becomes liable for a debt contracted by his copartners, a joint debt is created, and the creditor is a joint creditor of the firm. Separate debts are those for which the creditor can have his remedy at law against that partner only who contracted them.

Particular Partnerships, Joint-Stock Companies, Banks, Mines, and Ships.

Joint-stock companies are such companies as are unincorporated, and which trade upon a joint stock. All trading associations, however numerous, and although unsupported by charter or act of parliament, are legal, provided their purposes be legal, and provided they do not attempt to exercise the privileges of a corporation, such as the power of making their shares transferrable at the will of the holder. If a man execute the deed of settlement of a company or association of individuals, or if by his letters or admissions it can be proved that he was really a partner according to the terms of that deed; or if he be proved to have done acts of management; or if he become a director, or otherwise hold himself out to the world as a partner, he is legally a partner in the company. The most conclusive evidence of partnership is the signing of the deed of settlement. But the signing of a prospectus of an intended company does not make a man liable to third persons.

The partners in joint-stock companies are of two classes: one consists of directors, trustees, and others who are actively employed in conducting the concern; the other, of a number of persons who take little or no part in its management, and many of whom become shareholders for the sake only of a profitable investment of their money. The general conduct of the trade falls upon the directors, whilst the more particular transactions are usually managed by paid agents who are not shareholders. The funds and other property of the company are vested in the trustees. The deed of settlement is a covenant made between a few of the shareholders chosen as trustees for that purpose, and the others; by which each of the latter covenants with the trustees, and each of the trustees covenants with the rest of the shareholders, for the due performance of a series of articles which are specifically set forth, and which point out the duties of the trustees, directors, and auditors; define their powers, and all other necessary matters. In all matters which might have been provided by the deed, but are not, the general law of partnership prevails. Unless therefore there be a stipulation to the contrary, every proprietor has a right to have free access at all times to the books of the company,

It follows from the nature of partnerships that a partner cannot assign his interest so as to make a stranger a partner. In order therefore that the shareholders of a trading company may be able to do this, there must be a provision to that effect in the deed. But as these shares cannot be legally transferred at the sole will of the holder, provisions must be inserted in the deed for giving due notice to the directors of the intended transfer or assignment. If a party having signed the deed wishes to retire from the concern, he must conform to the stipulations of the deed, which usually provides that any proprietor shall be permitted to retire upon payment of a certain sum in respect of his share, and upon giving notice to the directors. The legatees or next of kin of a shareholder become beneficially entitled to his interest in the company upon his decease, but neither they nor his executors or administrators will be entitled to stand in his situation as a partner, unless permitted to do so by the deed of settlement.

The private property, to its full extent, of every member of an unincorporated trading company is liable for the whole debts of the company. The most important object to be gained by an act of parliament for a joint-stock company is by the clause which enables it to sue and be sued through the medium of one of its officers; without which advantage the difficulties attendant upon suits by or against such companies are beyond calculation. The Court of Chancery however seems inclined to diminish the difficulties, for (in Taylor *v.* Salmon, 4 M. & C. 134) it was held that in a suit by the directors of a joint-stock company on behalf of themselves and all other shareholders to have the benefit of an agreement entered into by an agent of the company, not necessary that all the shareholders should be made parties.

With respect to banks, in the several acts of parliament relating to them restrictions are put upon the number of partners in those of a private nature, or, in other words, in private banks; but these restrictions have been in a great degree removed. Formerly no more than six persons could carry on the business of banking, but by 7 George IV., c. 46, more than six may do so in England, sixty-five miles from London, provided they have no house of business or establishment as bankers in London. Every member of the copartnership is responsible for all the debts of the company: they must not draw bills for less than 50*l.* upon any person living within sixty-five miles of London, and they must deliver to the stamp-office a statement of the names and places of abode of all the members, and also a list of their officers. They must also, by their secretary or other proper officer, send to the stamp-office a statement of the change of every officer, and of the names of all who cease to be proprietors or become new proprietors during the year. In Ireland, under the provisions of 1 and 2 George IV., c. 72, private banks may consist of more than six partners, if situate more than fifty Irish miles from Dublin. In Scotland there is no restriction of the number of partners.

A partnership in the working of a mine is considered by courts of equity as a partnership in a trade, and therefore subject to the usual rules as to partnership.

The legal condition of part-owners of ships is considered under SHIP.

The chief rules of Roman law as to partnership may be collected from Gaius, iii. 148-154; *Dig.*, xvii., tit. 2; Cicero, *Pro Publio Quintio*.

(Collyer 'On Partnership.')

PARTRIDGE. [PERDICIDÆ.]

PARTRIDGE WOOD, a kind of wood much esteemed for cabinet-work on account of its beautiful variegated and barred appearance, is commonly said to be furnished by the *Heisteria coccinea* of botanists, a small inelegant tree, about twenty feet high, found in Martinique by the side of torrents; but this appears to be a mistake which has arisen out of the name given to Heisteria in that colony. In the corrupt French of Martinique it is called *Bois Perdrix*, a name which, as Jacquin tells us, does not signify partridge-*wood*, but Partridge-*pea*, bois being used for pois; and the name is given to the plant, not because of the variegated wood resembling a partridge's wing, but because the wild pigeons are fond of the berries. Partridge-wood is said by Guibourt, who does not however give any authority for the statement, to be really a product of Cayenne, where it forms a tree 60 feet high, and is called Boco. Of this plant, called by Aublet *Bocoa prouacensis*, an account will be found in that author's *Plantes de la Guiane Française*, Supp., p. 38, t. 394; but it is now wholly unknown to botanists, its very name being omitted even in the most complete botanical systems. Aublet says it is found in the woods of Caux; and he supposes that its hard heart-wood would be a good material for the blocks or pulleys used in machinery; but he says nothing of its being exported to Europe.

PARTULA, a genus established by Férussac for a form of the family *Colimacea*, Lam. (*Auriculacea* of Férussac).

Generic Character.—*Animal* elongated, demicylindrical; *tentacles* two, cylindrical and retractile, ocellated at their summit. Ovoviviparous. Terrestrial.

Shell oval, pointed; spire conical, last whorl tumid, and larger than the rest put together; spiral whorls four to six. Aperture straight in the direction of the axis, short, sometimes toothed or furnished with elevated plates; peristome commonly very much reflected, with the edges on the same vertical plane; columellar side of the aperture callous at its base. Dextral or sinistral.

In addition to the species described by M. de Férussac, Broderip has described some brought home by Mr. Cuming, and collected by him in the islands (Polynesia) Otaheite and Huaheine, principally on the *Ti* plant and on bushes. (*Zool. Proc.*, 1832; Müller, *Synopsis*, 1836.)

PARUS. [TITMOUSE.]

PARUTA, PAOLO, born at Venice, in 1540, of a patrician family, studied in the university of Padua, and afterwards entered on the career of diplomacy. In 1562 he accompanied the Venetian ambassador, who was sent to Vienna to congratulate Maximilian II. on his accession to the throne. On his return he stopped at Trento, where the council was then assembled, and where he conceived the plan of his dialogues on political life, 'Della Perfezione della Vita Politica Libri III.,' in which he introduces two prelates of the council as the interlocutors. On his return to Venice, he filled several official stations in the service of his country, and in the year 1592 was sent ambassador to Pope Clement VIII. at Rome. He was there instrumental in persuading the pontiff to grant absolution to Henri IV. of France, and thus reconciling the latter with the church of Rome. (Andrea Morosini, *Storia Veneta*, b. xv.) While at Rome, he says, a change took place in his ideas, which had till then been turned towards ambition and worldly pursuits. He asked himself, 'What am I doing in this world? what am I thinking of? and what do I expect in the end?' The process and result of his self-examination, in which he recapitulated the whole of his past conduct, he has given us in his 'Soliloquy,' published at the end of his 'Discorsi Politici,' which forms a useful moral treatise.

Before he went to Rome he was appointed historiographer to the republic, in which capacity he continued the history of his country from 1513, where his predecessor Luigi Contarini had left it. The 'Istoria Veneziana dal 1513 al 1551' of Paruta is divided into twelve books. A distinguished Italian critic, Apostolo Zeno, says of this work, that 'the author has fulfilled the duties of a grave and able historian, both in respect to the veracity of his narrative and the dignity of his style.' Paruta also wrote a separate history of the eventful war of the Venetians against the Turks in the island of Cyprus in 1570-72, in three books. The histories of Paruta are not mere dry narratives of political or military events; they are intermixed with information and reflections concerning the civil history of the people, and the customs, manners, and opinions of the age. That branch of political knowledge now known by the name of statistics was attended to at Venice much sooner than in any other modern state, and Paruta had early applied himself to it.

Paruta's 'Political Discourses,' in two books, are a series of disquisitions upon the history of Greece and Rome, as well as upon various passages of modern history, and deserve, for their impartiality and statesmanlike penetration, to be put by the side of Machiavelli's 'Discourses on Livy.' Montesquieu is said to have availed himself of Paruta's 'Discourses' in the composition of his works. (Corniani, *Secoli della Letteratura Italiana*, art. 'Paruta.')

Paruta, after returning from his embassy at Rome, was made a knight and procuratore of St. Mark, and shortly after died at Venice, in 1598.

PAS DE CALAIS, a department in the northern part of France, bounded on the north-east and east by the department of Nord; on the north-west and west by the Strait of Dover (called by the French Pas de Calais, from which the department takes its name), and the English Channel (or La Manche); and on the south by the department of Somme. The form is irregular, having its greatest length from Cape Gris-Nez, at its north-western extremity, to the neighbourhood of Bapaume, at its south-eastern extremity, 87 miles, and its greatest breadth from the mouth of the Aa to that of the Authie, nearly 50 miles. The area is estimated at 2558 square miles, being considerably above the average area of the French departments, and rather less than the area of the English county of Devon (2585 square miles). The population, in 1831, was 655,215; in 1836, it was 664,654; showing an increase in five years of 9439, and giving nearly 262 inhabitants to a square mile. In amount and density of population it is very far above the average of France, and is exceeded in either respect by very few of the French departments; it is far superior to Devonshire. Arras, the chief town, is about 100 miles north by east of Paris in a direct line, or 109 miles through Senlis, Roye, Peronne, and Bapaume.

A ridge of high ground separating the streams which flow into the English Channel from those which fall into the North Sea enters the department near its south-eastern extremity, and for some distance runs westward, keeping near the southern border; it then turns more to the north-west, and terminates in the high cliffs of Cape Gris-Nez, between Calais and Boulogne. The department is comprehended in the chalk district which surrounds the Paris basin, and the cliffs of Gris-Nez, which are composed of chalk, bear a close resemblance to those of Dover. These cliffs extend for a few miles on each side of the headland; in some other parts the coast is low, and defended from the sea at high water by a natural barrier of sandy downs. The harbours are few, and none of them good, being encumbered with sand or the débris of the cliffs. Boulogne and Calais are the principal. The mineral treasures of the department comprehend limestone, sandstone, potters'-earth, some varieties of marble, coal, and peat. There is only one coal-pit, which in 1834 gave employment to 165 labourers, of whom 118 worked in the pit. The quantity of coal produced that year was 4461 tons; in 1835 the produce was 3736 tons. There was, in 1834, one iron-work, containing seven forges for making wrought-iron; coal and coke were the fuel employed.

The rivers and streams rise chiefly on the north-eastern slope of that ridge of high land which traverses the department. The Sensée, the Scarpe, and the Lys are feeders of the Escaut, or Schelde. The Sensée rises near Bapaume, and flows north-east 16 miles to L'Ecluse, on the border of the department of Nord, and then eastward along the border for about six miles more. It receives the Cojeuil and the Hirondelle. The Scarpe rises between St. Pol and Arras, and flows east to Arras, just above which it receives the Gy. At Arras it becomes navigable, and flows still eastward past Vitry to Douay in the department of Nord. Its whole course in the department of Pas de Calais may be estimated at 26 miles, for more than half of which it is navigable. The Lys rises near Fruges, and flows north-east past Therouenne to Aire, where it is made navigable, and flows eastward into the department of Nord. It afterwards skirts for a short distance the boundary of the two departments. The Nave and the Clarence unite and flow into the Lys; and the Lawe, which becomes navigable at Bethune, falls into the same river. The Souchez flows into the Deule, a tributary of the Lys, belonging to the department of Nord. The Aa rises between Montreuil and St. Omer, flows past St. Omer to the boundary of the department, and then along the boundary into the sea at Gravelines. Its whole course is about 50 miles: it is navigable from St. Omer.

The rivers on the southern slope are the Liane, the Canche, and the Authie, the last of which separates this department from that of Somme. The Liane, which is very small, flows into the harbour of Boulogne. The Canche rises not far from the head of the Scarpe, and has a north-westward course of about 44 miles, past Hesdin, Montreuil, and Etaples: it is navigable from Montreuil to the sea, about 8 miles. It receives the Ternoise (which in some maps is also called Canche) from the neighbourhood of St. Pol. The Authie rises just on the border of the department, and has the first few miles of its course in that of Somme. It then touches the border again, and flows north-west into the sea. Its whole course is above 50 miles, but no part of it is navigable.

The Calais and St. Omer canal extends from Calais to the Aa, by the navigation of which it communicates with St. Omer: it has two short branches, the canals of Guines and of Ardres. From St. Omer the line of inland navigation is continued by the Neuf-Fossé canal to Aire; and from Aire by another canal to La Bassée, just within the department of Nord. Part of the Haute Deule navigation between Douay and Lille (Nord) passes through this department east of Lens. The whole of the inland navigation of the department is thus given in the official statements (*Statistique de la France*):—

Rivers.	Miles.	Canals.	Miles.
Aa . .	19	Calais and St. Omer canal .	18½
Canche .	7½	Guines branch . . .	4
Lawe . .	9	Ardres ditto . . .	3
Lys . .	6½	Neuf-Fossé canal . .	6½
Scarpe . .	15	Aire and La Bassée canal .	24
	—	Haute Deule canal .	11
	57		——
		Total of canal navigation	67
		Total of river navigation	57
			——
		Total of inland navigation	124

The department is traversed by thirteen government roads (*Routes Royales*), having an aggregate length of 423 miles, viz. 232 miles in good repair and 191 miles out of repair; and by forty four roads under the direction of the depart- authorities (*Routes Départmentales*), having an ag- length of 217 miles, viz. 101 in good repair, 58 out r, and 58 unfinished. The principal roads are those to Calais, Dunkerque, and Lille. The main road from Paris to Calais enters the department by a bridge over the Authie at Nampont, and passes by Montreuil, Samer, and Boulogne. Another and more inland road to Calais passes by Hesdin, Fruges, Fauquemberg, St. Omer, and Ardres. One road to Dunkerque passes by St. Pol, Pernes, Lillers, and Aire; and another by Bapaume, Arras, Béthune, and Lillers, where it joins the other road. There are three roads to Lille, one by St. Pol, Béthune, and La Bassée; the second by Arras and Lens; and the third and principal one by Cambray, which just crosses the eastern extremity of the department. There are cross-roads from Montreuil by Hesdin, St. Pol, and Arras to Cambray; from Boulogne by St. Omer, Aire, Lillers, Béthune, and Lens to Douay; from Calais by Gravelines to Dunkerque; and there are roads from Arras to Béthune, to Lens, to Douay (Nord), and to Doulens and Abbeville. A road from Paris by Amiens to Cambray passes through Bapaume.

The climate of the department is changeable; the soil is generally fertile, and well cultivated. The farms are of greater extent and the agricultural operations are carried on on a larger scale than is usual in France. The area of the department is estimated at more than 1,600,000 acres, and nearly four-fifths of it are under the plough. The grain principally cultivated is wheat, the produce of which is more than three times as great as the average produce of the French departments: in rye and maslin, as well as in barley, the produce is considerably below the average, and in oats little more than one-third of the average. From the great preponderance of the wheat crop, the grain harvest is however, as a whole, nearly double the average of the other departments. Potatoes are cultivated to a considerable extent; and in the northern part of the department, where the husbandry is assimilated to that of the department of Nord, colza, rape, and other oleaginous plants are much grown, as also beet-root for the manufacture of sugar. The refuse, after the extraction of the sugar, is used for sheep feed, and is so valuable as to pay for a large part of labour of manufacturing the sugar. The meadow land comprehends more than 100,000 acres, and there are 40,000 acres of heath or other open pasture-ground. The number of horses is nearly three times the average number in the French departments: the excess is owing to their being employed more extensively than usual in the labours of agriculture. In the number of cows and heifers this department has also a great predominance, but in the number of bulls and oxen it falls very short. On the whole, the number of horned cattle is considerably above the average of the departments; and the same is the case with sheep, of which many are merinos, or of the long-woolled English breeds. Swine and poultry are abundant. The woodlands occupy about 100,000 acres, but are not sufficient to supply the department with fuel. A considerable quantity of coal is imported from the department of Nord and from Belgium. Orchards are very general, and occupy from 45,000 to 50,000 acres. The climate does not admit the growth of the vine. Wine, imported from the other departments, and beer, are the common beverage of the inhabitants.

The department is divided into six arrondissemens, as follows:—

		Area in Sq. Miles.	Population. 1831.	1836.
Arras	S.E.	535	163,672	163,032
Béthune	N.E.	357	131,849	131,973
St. Omer	N.	419	103,073	105,020
St. Pol	S.	437	80,676	80,566
Boulogne	N.W.	364	98,099	105,465
Montreuil	S.W.	436	77,846	78,658
		2538	655,215	664,654

The number of cantons or districts, each under a justice of the peace, is 43; the number of communes 903, viz. the arrondissement of Arras 211, of Béthune 142, of St. Omer 117, of St. Pol 193, of Boulogne 99, and of Montreuil 141.

In the arrondissement of Arras are—Arras, the capital of the department (population in 1831, 23,419; in 1836, [illegible]) [ARRAS] and Vitry (population 2276 town, 2310 whole commune), on the Scarpe; Bapaume (population 3071 town, 3195 whole commune), near the source of the Sensée [BAPAUME]; Oisy (population 2116 town, 2148 whole commune), near the Hirondelle; and Pas, near the source of the Authie. Peat is dug in the neighbourhood of Oisy. It has oil-presses and tan-yards; some manufactures of cot yarn and cotton velvet are carried on. There are twelve fairs in the year. The population is about 7000.

In the arrondissement of Béthune are—Béthune (population in 1831, 6889; in 1836, 6903) [Béthune], Houdain, and La Ventie, on or near the Lawe; Lens (population 2561), near the Souchez; Hénin-Liétard (population 3030), between Lens and Douay; Carvin-Epinoy (population 4254 town, 4962 whole commune), between Lens and Lille; Lillers (population 2319 town, 4891 whole commune), and St. Venant, on or near the Nave. Lens was once a place of strength, and was repeatedly taken in the wars of which Artois and Flanders were the seat; it is best known in history from the great victory obtained here (A.D. 1648) by the French, under the prince of Condé, over the Spaniards. The inhabitants distil potato spirit, and manufacture leather and soap. Clay is dug near the town. There is an hospital at Lens. At Hénin-Liétard oil is expressed and lawn manufactured. There are two fairs for cattle and hardwares. Lillers was once a place of strength, but the fortifications have been destroyed. It is agreeably situated in a fine plain, and has a handsome place or square, in which its two yearly fairs are held. The houses are for the most part well supplied with water by copious fountains on the premises. There are tanyards, breweries, oil-mills, and potteries, and some trade is carried on in linen yarn and linens. St. Venant, with a population of about 1000, is a fortified town in a low and swampy situation. It was taken by the allies under Marlborough and Eugene in 1710. The inhabitants are engaged in expressing oil, tanning, and brewing. There is one yearly fair. St. Venant has an hospital.

In the arrondissement of St. Omer are—St. Omer (population in 1831, 19,344; in 1836, 19,032) [Omer, St.] and Fauquemberg, on the Aa; Therouenne and Aire (population 8431 town, 9725 whole commune), on the Lys [Aire]; Tournehem and Audruick (population 2287), on or near the Hem, a small feeder of the Aa; and Ardres (population 2016) on the road from Calais to St. Omer. Fauquemberg, with a population of about 1000, has a considerable corn and cattle market. Therouenne, the Tarvenna of the Romans, was in the middle ages the capital of a county. It was taken from the French by Henry VIII. of England, A.D. 1513, but restored soon after, and again taken, A.D. 1553, by the emperor Charles V., who took revenge for the brave resistance of the townsmen by the destruction of the town. Ardres is a fortified town, but is very small. It was taken from the French by the Spaniards, A.D. 1596, but restored two years afterwards at the peace of Vervins.

In the arrondissement of St. Pol are—St. Pol (population in 1831, 3504; in 1836, 3452), on the Ternoise, an affluent of the Canche; Frévent (population 2071) and Vieil (or Old) Hesdin, on or near the Canche; Auxy or Auxi le-Château (population 2794), on the Authie; Pernes, on the Clarence; Aubigny, on the Scarpe; and Avesne-le-Comte, at the source of the Gy. St. Pol was in the middle ages the capital of a county. It was taken and retaken in the wars between François I. of France and the emperor Charles V., and finally ceded to France by the treaty of the Pyrenees (A.D. 1659). The town is pleasantly situated in a picturesque country: it has some remains of the antient fortifications, and of the castle of the counts of St. Pol. The inhabitants express oil, manufacture dimity and nankeen, and carry on trade in wheat, oats, hay, and some tobacco, which are grown in the neighbourhood. There are a subordinate court of justice, a high school, and one or two government fiscal offices. Frévent is a small but neat town, like a Flemish town. The townsmen are chiefly engaged in the wool trade. Vieil Hesdin, now a small place, was once of more consequence, but was destroyed by the emperor Charles V. Auxy le Château is in a marshy situation: the inhabitants manufacture some cotton yarn. At Aubigny cotton yarn and earthenware are manufactured. The village of Azincourt or Agincourt is in this arrondissement. [Agincourt.]

In the arrondissement of Boulogne are—Boulogne-sur-Mer (population in 1831, 20,856; in 1836, 25,732) [Boulogne], Ambleteuse, Wissant, and Calais (population 10,827) [Calais], on the sea; Guines (population 4279 town, [illegible] whole commune) near Calais; Samer, on the Liane; Desvres (population 2572 town, 2621 whole commune), Le Wast, and Licques, in the inland part of the arrondissement. Ambleteuse, a small town, with a port choked up with sand, was the place where James II. disembarked in his flight from England (A.D. 1689). Wissant, or Witsand, was probably the Itius Portus of Cæsar and other antient writers: the port is now choked with sand. Guines was in the middle ages a place of great strength, and the capital of a county. It was between Guines and Ardres that the celebrated interview of 'the field of the cloth of gold' took place between Henry VIII. of England and François I. of France, (A.D. 1520). The town, which is in a low marshy flat, where peat is dug, is now without fortifications. The townsmen trade in corn, cattle, poultry, and game. Samer is pleasantly situated on a hill; four streets meet in the market-place, which is large but irregular. The population is about 2000. Desvres is on the slope of a hill; the houses are built of stone, and there is a good market-place. Coarse woollen cloth, earthenware, and leather are manufactured. There are two yearly fairs.

In the arrondissement of Montreuil are—Montreuil (population in 1831, 4093; in 1836, 3867); Hesdin (population 3455), and Etaples (population 1764), on the Canche; Fruges (population 3085), near the head of the Lys; and Hucqueliers, near the head of the Aa. Montreuil was a place of strength in the middle ages, and was frequently besieged. Henri IV. augmented the fortifications, designing to make it a bulwark against the Spaniards, who then possessed Arras. It is still fortified; but the citadel, built on an eminence, is the only part which possesses any real strength. The principal street of the town is crooked but tolerably wide; all the houses are of brick. There are a subordinate court of justice, some government fiscal offices, a high school, a public library, an agricultural society, and two hospitals, one of them for foundlings. There are salt-refining houses, soap-houses, breweries, tanneries, rope-walks, and tile or other earthenware works. Linen cloth is made, and trade is carried on in groceries, wine, and brandy. There is one yearly fair. Montreuil is called Montreuil-sur-Mer, but is really 7 or 8 miles from the sea. Hesdin, in a marshy and unhealthy situation, is a place of some strength. It was built by the emperor Charles V., in place of Vieil Hesdin, which he had destroyed. It is defended by a wall, strengthened by bastions and considerable outworks. The ditches are always kept full by the Canche, which runs through the town. Hesdin is a neat place, with a church and a house of correction. The townsmen manufacture stockings, leather, soap, bricks, tiles, and earthenware, and express oil. There are three fairs, one held for a fortnight for horses, cattle, and agricultural produce. Good peat is dug near the town. Hesdin was ceded to the French by the treaty of the Pyrenees, A.D. 1659. Etaples, in the midst of sandy downs which line the coast, was formerly a place of strength, defended by a castle, now in ruins. It has now a salt-refining house, and some breweries and distilleries of corn-spirit. Snuff and salt are exported, and the herring and mackerel fisheries are actively carried on. At Fruges, ordinary woollen cloths and cotton and worsted stockings are manufactured; and trade is carried on in leather and shoes. There are two yearly fairs. Hucqueliers has two horse-fairs.

The manufactures of the department are very considerable: linen and cotton yarn and goods, woollen cloths and stuffs, lace, hosiery, paper, glass, gunpowder, starch, soap, clay-pipes, and other earthenware are manufactured; salt-refining, seed crushing for oil, brewing, distilling corn-spirit, tanning, brick and tile making, and the manufacture of beet-root sugar are carried on: the inhabitants of the coast are engaged in fishing.

The department constitutes the diocese of Arras, the bishop of which is a suffragan of the archbishop of Paris. It is in the jurisdiction of the Cour Royale of Douay, and in the circuit of the Académie Universitaire of that city. It is in the sixteenth military division, the head-quarters of which are at Lille. It returns eight members to the Chamber of Deputies. In respect of education it is considerably above the average of the French departments. Of the young men enrolled in the military census of 1828-9, 42 in every 100 could read and write, the average of France being little more than 39.

In the most antient period the country now forming this department was comprehended in the territories of the Ambiani, the Morini, and the Atrebates, three Belgic nations. The Ambiani occupied the southern part between the Authie and the Canche; the other tribes occupied the parts north of the Canche, the Morini on the sea-coast, and the Atrebates inland. All these nations joined the great Belgic confederacy against Cæsar, in the second year of his command in Gaul (B.C. 57). Upon the defeat of the confederacy, the Ambiani submitted; the others held out for a time; but the Atrebates, having shared in the great defeat sustained by the Nervii, were forced to yield, and were placed under the dominion of Commius, an Atrebatian and a friend of Cæsar; and the Morini, after assisting the Veneti in their naval struggle with the Romans (B.C. 56), for the most part submitted when Cæsar was in their country preparing for his first expedition into Britain (B.C. 55). They too were placed under the government of Commius. (Cæs., *De Bell. Gall.*, vii. 76.)

In the great revolt under Vercingetorix (B.C. 52) these nations all joined the Gallic confederacy, of which Commius was one of the chiefs. In the subsequent division of Gaul, the three nations were included in the province of Belgica Secunda. There were several Roman towns within the limits of the department. Taruenna, now Thérouenne, was the capital of the Morini; and Gesoriacum, afterwards Bononia, now Boulogne, and Itius or Iccius Portus, now Wit-sand or Wissant, also belonged to them. The *Portus ulterior* or *superior*, from which the transports with the cavalry sailed, on Cæsar's first expedition to Britain, was probably at or near Calais; and Marci mentioned in the 'Notitia Imperii' was perhaps Mark, between Calais and Gravelines. The Luttomagus, Adlullia, and Duroicoregum of the Theodosian or Peutinger Table, are fixed by conjecture at positions on the road from Bononia (Boulogne) to Samarobriva or Ambiani (Amiens), within the limits of the department. Duroicoregum, which belonged to the Ambiani, is supposed to be the modern Douriers on the Authie. The Teucera of the Theodosian Table, which was also in the territory of the Ambiani, may perhaps be fixed at Thièvre, on the Authie, near Pas. The only town of the Atrebates, known to have been within the limits of the department, was Nemetacum, their capital, afterwards called Atrebates, now Arras. Gesoriacum, or Bononia, was held by the usurper Carausius, from whom it was taken by Constantius Chlorus.

In the middle ages the department was divided between the provinces of Picardie and Artois. By far the greater part was included in Artois; a narrow strip along the coast formed the districts of Calais and Boulogne, or Le Calaisis and Le Boulonnois, and the part south of the Canche was included in the county of Ponthieu, all in Picardie. In the wars of the English kings Edward III. and Henry V., this part of France was the scene of contest. Edward III. besieged and took Calais (A.D. 1347), which, with the territory round it, remained in the power of the English, until it was retaken by the duke of Guise (A.D. 1558). The district of Calais was sometimes called from this circumstance Le Pays Reconquis. Henry V. fought the battle of Agincourt (A.D. 1415), when intercepted in his retreat to Calais. Boulogne was taken by Henry VIII. of England, A.D. 1544, and restored by Edward VI. (A.D. 1550). Boulogne was in 1803-4 the centre of the preparations made by Bonaparte for the invasion of England.

(Malte Brun, *Géographie Universelle*; *Dictionnaire Géographique Universelle*; Dupin, *Forces productives de la France*; Vayse de Villiers, *Itinéraire Descriptif, &c.*)

PASA'RGADÆ (sometimes written *Passargadæ*, and also, but only by Ptolemy and Solinus, *Pasargada*), an antient town of Persia, which is said to have been built by Cyrus after his victory over Astyages the Mede, which he gained near this place. (Strabo, xv. 730; Curt., v. 6.) The kings of Persia, according to Plutarch (*Artax.*), were consecrated at Pasargadæ by the Magi, and here was the tomb of Cyrus, of which Strabo (xv. 730) and Arrian (vi. 30) have given a description taken from the work of Aristobulus, who had visited the spot. According to their descriptions, the tomb was situated in a well-watered park, and was surrounded by numerous trees. The lower part of it, which was solid, was of a quadrangular shape, and above it was a chamber built of stone, with an entrance so very narrow that a man could with difficulty get into it. Aristobulus entered this chamber by command of Alexander, and found in it a golden couch, a table with cups upon it, a golden coffin, and many beautiful garments, swords, and chains. Aristobulus says the inscription on the tomb was, 'O man, I am Cyrus, who acquired sovereignty for the Persians, and was king of Asia. Do not then grudge me the monument.' There were certain Magi appointed to guard the tomb, who received every day a sheep and a certain quantity of wine and wheat, and also a horse every month as an offering to Cyrus. This tomb was plundered during the lifetime of Alexander by some robbers, who carried off everything except the couch and the coffin.

The position of Pasargadæ has been a subject of much dispute. Many writers think that Pasargadæ and Persepolis are only different names for the same place, and that the latter word is the Greek translation of the former. There appears however little doubt that they are distinct places. Strabo (xv. 729) speaks of them as such, and Arrian informs us that Alexander, in his return from Karmania, came to Pasargadæ in Persis, where he found the tomb of Cyrus plundered (vi. 29), and that thence he proceeded to the royal dwelling of the Persians (vi. 30), which must mean Persepolis. And again, in the beginning of the next book (vii. 1), he says, 'When Alexander came to Pasargadæ and Persepolis,' &c. Pliny (vi. 29) also speaks of 'Persæpolis' and 'Passagardæ' as distinct places, and says that the latter was to the east of a town called Laodicea, of the position of which we know nothing.

But although we may have strong grounds for believing that Pasargadæ and Persepolis are different places, it is difficult to determine the site of the former. Many modern writers have been disposed to place it in the plain of Murghab, about fifty miles north-east of Persepolis, in consequence of the remarks of Mr. Morier (*Journey in Persia*, p. 144) and Sir Robert K. Porter (*Travels*, vol. i. p. 498), who discovered a building in that plain, which they imagined to be the tomb of Cyrus. This building is called by the people of the country 'Kubr Maderi Suleiman,' or the tomb of the mother of Solomon; and the description given by Sir Robert K. Porter corresponds in many particulars to that of Arrian and Strabo. The tomb contains no inscription, but on a pillar in the neighbourhood there is a cuneiform inscription, which Grotefend, in an essay on this subject appended to Heeren's work on Asia (vol. ii., p. 360-75, Engl. transl.), interprets to mean 'Cyrus the king, ruler of the universe.' Saint-Martin however (*Journal Asiatique* for February, 1828) supposes that it rather refers to Artaxerxes Ochus; and Lassen, a most competent authority upon this subject, thinks that it is impossible to make out the name of Cyrus in the inscription. Hoeck (*Veteris Mediæ et Persiæ Monumenta*, Gött., 1818) thinks the building described by Morier and Porter to be the tomb of one of the Sassanian kings, the dynasty that ruled in Persia from the third to the middle of the seventh century of the Christian æra.

Lassen, who has examined the subject with great care and diligence (*Ersch und Gruber's Encyclop.*, art. 'Pasargadæ') thinks that we ought to look for Pasargadæ south-east of Persepolis, in the neighbourhood of Darabgherd or Fasa.

Herodotus does not speak of Pasargadæ as a place, but as the noblest of the Persian tribes (i. 125).

Stephanus of Byzantium says that Pasargadæ, or, as he writes it, Passargadæ, means the 'camp of the Persians;' but Lassen makes it mean 'the treasury of the Persians.'

PASCAL, BLAISE, a distinguished French philosopher, justly characterised by Bayle as 'one of the sublimest spirits in the world,' was born at Clermont in Auvergne, June 9, 1623. He was the only son of Etienne Pascal, president of the Court of Aids in that province, himself a learned and respectable man and able mathematician, who, when his boy had reached his eighth year, resigned his office and removed to Paris, for the purpose of watching over his education. From his childhood, Blaise displayed abilities far above the common order, and evinced so inquisitive a spirit that, as his sister has recorded, he would not rest without knowing the reason of everything. The bent of his infantine genius was decidedly mathematical; but his father, who was his only preceptor, and who was anxious that his attention should not be distracted from the study of the dead languages, resolved to exclude every notion of geometry from his mind, removed all books which treated of that science, and even abstained in the child's presence from any conversation on mathematical subjects with his friends. Notwithstanding these precautions however, young Blaise, when only in his twelfth year, without the aid of books or oral instruction, began to draw figures with charcoal on the floor of his room, and had, without any assistance, made some progress in geometry before his father surprised him in these researches.

After this discovery, he was thwarted no more in the pursuit of mathematical investigations; and at sixteen years of age he produced a treatise on the conic sections, of an-excellence as to provoke the incredulity and wonder of Des Cartes, who would not believe that so extraordinary a performance was the work of a mere youth. In his nineteenth year he invented an ingenious machine for making arithmetical calculations, which excited the admiration of his times; and, afterwards, at the age of twenty-four years the conjecture of Torricelli that the atmosphere had weight, and that this quality might account for effects before ascribed to the horror of a vacuum, led him to institute many able and successful experiments on this subject, which confirmed the truth of Torricelli's idea, and established his own scientific reputation. The results of these labours were collected into two essays, which appeared after his death, 'On the Equilibrium of Liquids,' and 'On the Weight of the Atmosphere.'

From these researches, made before he had completed his twenty-fifth year, the great mind of Pascal was diverted entirely to objects of religious contemplation; and thenceforward he abandoned almost entirely the pursuits of science. He had been all his life as remarkable for piety as for genius; and it is the testimony of a learned biographer, whose opinions were far from resembling his own, that he knew exactly how to distinguish between the rights of faith and of reason. The conviction of Pascal may therefore with propriety be cited among the most striking and satisfactory examples of the deep submission of the most powerful intellects to the truths of revelation; while it also may be considered with other illustrious exceptions to the reproach that the high cultivation of mathematical science is little favourable to piety. It is no fair objection to the value of his example, that Pascal, under the nervous excitation of bodily disease, fell into many absurd excesses of fanaticism; that he practised the most rigid abstinence from all worldly enjoyments, and wore next his skin a cincture of iron studded with points, which he struck with his elbow into his flesh, as a punishment to himself whenever any sinful thought obtruded itself into his mind. Such things may be ascribed to the inherent weakness of our corporeal nature, to some of the ordinary caprices of human disposition, or to the imaginative delusions attendant upon a particular state of bodily health; but they detract nothing from the soundness of the anterior investigation which had led a pure and unclouded reason like that of Pascal to embrace the doctrines of revelation, by a process analogous to that which had conducted him to the discovery of abstract truth.

It is a curious exemplification of the anomalous conditions of the human mind, that, while Pascal was immersed in these superstitious observances, he published his famous 'Provincial Letters,' in which, under the name of Louis de Montalte, he assailed the morality of the Jesuits with equal wit and argumentative acumen. He was induced to write this work by his adoption of the opinions of the Jansenists, which he warmly espoused, and which involved him in the religious disputes of his age and country. Among the fruits of his devotional exercises may also be named his 'Pensées,' which were collected and published after his death; and in which he has beautifully availed himself of an idea of one of the ancient fathers, that he who believes in the existence of a God gains eternally if he be right, and loses nothing if wrong; while the atheist gains nothing if right, and renders himself miserable eternally if he be wrong. The weakly frame of Pascal was reduced to premature old age by infirmities, which were aggravated by his ascetic habits, but which he bore with exemplary patience; and he died in Paris in 1662, at the age of thirty-nine years. His Life was written elaborately by his sister Madame Perier; and has afforded the materials for an able and interesting article in the Dictionary of Bayle.

PASCAGOULA, River. [MISSISSIPPI, RIVER.]

PASCHAL I. was elected bishop of Rome after the death of Stephen V., A.D. 817. To him the pretended donation by the emperor Louis the Pious is said to have been made. [PAPAL STATE.] He crowned as emperor Lothaire, son of Louis the Pious, in the year 823, and died the following year. He was succeeded by Eugenius II.

PASCHAL II., Ranieri of Bieda in Tuscany, was a monk of the order of Cluni. Having been sent to Rome about the affairs of his monastery, he was noticed by Pope Gregory VII., who made him a cardinal. After Gregory's death, and the short pontificate of Urban II., Paschal was elected pope. He refused the dignity, and even concealed himself, but was at last prevailed upon to accept the papal chair, A.D. 1099. He continued the great contest about the investitures, begun by Gregory VII. with the emperor Henry IV., against whom he launched a fresh bull of excommunication. Henry's son and namesake, availing himself of this, revolted against his father, and, having deposed him, was acknowledged as king of the Germans by the title of Henry V. He then proceeded to Italy with an army, in order to get himself crowned emperor. On the question of the investitures he was as stubborn as his father. After some conferences between him and the pope's ambassadors, Paschal proposed what appeared to be a reasonable compromise of the matter in dispute. 'If the emperor,' said he, 'contends for his royal rights, let him resume the donations on which those rights are founded, the duchies, margraviates, countships, towns, and manors, which his predecessors have bestowed on the Church. Let the Church retain only its tithes and the donations which it has received from private bounty. If Henry *renounces* the right of investiture, the Church shall restore all it has received from secular princes since the time of Charlemagne.' (Pagi, *Vita Paschalis II.*; Fleury, *Hist. Eccles.* &c.) This proposal went to the root of the evil, and Paschal was probably sincere in making it; but the bishops, and especially the German bishops, who were possessed of large fiefs, strongly protested against it. In the mean time Henry arrived at Rome to be crowned, A.D. 1110. He kissed the pope's feet according to custom, and entered hand in hand with him into the church of the Vatican. But here an explanation took place concerning the compromise, the result of which was that the treaty was broken off, and Paschal refused to consecrate the emperor. The particulars have been differently related by the various writers. Some say that Paschal could not fulfil his proposed renunciation of the temporalities of the Church, owing to the opposition of the bishops; others say that Henry would not give up the right of investiture, because his councillors, and among the rest several German bishops who were about his person, unwilling to risk their domains and revenues, persuaded him not to renounce what they represented as an essential part of the imperial prerogatives and of the splendour of the imperial dignity. After repeated messages between the pope and the emperor, the latter, who wished to be crowned at all events, determined to frighten the pope into compliance. At the suggestion, it is said, of two German prelates, one of whom was the archbishop of Mainz, he ordered his German soldiers to lay hands on the pope. A scuffle ensued, and the people of Rome, irritated at seeing their pontiff prisoner, fell on the German soldiers, and drove them back with considerable slaughter to their camp outside of the town. Henry however kept possession of the person of the pope, whom he dragged after him, stripped of his pontifical ornaments and bound with cords. Paschal remained for nearly two months in a state of confinement, during which he was assailed by the remonstrances of his clergy, many of whom were prisoners with him in the German camp, until at last he yielded to their entreaties, and consented to consecrate Henry unconditionally, giving up by a bull the right of investiture to the emperor. After the *ceremony*, Henry returned to Germany, and Paschal thought it necessary to assemble a council in the Lateran to submit his conduct to the judgment of the Church. He declared to them at the same time that he would rather abdicate than break his word to the emperor, either by excommunicating or molesting him. After much deliberation, Paschal's *cession* of the right of investiture was solemnly condemned, and it was declared that the investiture of churchmen by lay hands was a heresy. The prelates of France and Italy, and even some of those of Germany, approved of the proceedings of the Lateran Council, and several of the turbulent German feudatories revolted against Henry. The emperor however kept the field, and, having defeated his revolted subjects, marched again to Italy to terminate the question with the see of Rome. Paschal, blamed and even personally insulted by the Romans because of his indulgence towards Henry, and threatened at the same time by the latter, escaped to Benevento, and Henry, having come to Rome, caused himself to be crowned again by the bishop of Benevento. After his departure, Paschal returned to Rome, but soon fell ill of fatigue and anxiety, and died in January, 1118, after a most stormy pontificate of eighteen years. He was succeeded by Gelasius II. The question of the investiture was settled by a compromise, in 1122, under Calixtus II., the successor of Gelasius. It was agreed that the bishops, being elected according to the canonical forms, should receive their regalia at the hand of the emperor and do homage for them, but that in this ceremony the emperor should no longer use the ring and crosier, the insignia of spiritual authority, but the sceptre only. Thus terminated a quarrel which had occasioned so much violence and bloodshed for half a century.

PASCHAL III., Antipope, was elected by the influence of the emperor Frederic I., in opposition to Alexander III., A.D. 1165. He took possession of Rome for a short time, Alexander being obliged to escape to Benevento, but he died shortly after, A.D. 1168. [ALEXANDER III.]

PASCHA'LE CHRO'NICON. [BYZANTINE HISTORIANS, p. 82.]

PA'SHA or **BASHA**, a Turkish appellation for a man in high command, such as the great officers of the Porte, the governors of provinces, and the high admiral, who is called Capudan Pasha. The provinces administered by Pashas are called Pashaliks. The Turks often write the word Pashah with an h at the end, as if it were a contraction or corruption of the Persian word Padishah, which is a compound of Pad, 'a guardian,' and Shah, 'king,' and which is the title assumed by the Ottoman Sultan, the king of Persia, the Mogul, and other great Eastern potentates. (Herbelot, *Bibliothèque Orientale.*) Some derive Pasha from the Persian Paï Shah, 'the foot of the king,' because those officers tread in the steps of the sovereign and stand in his place. (*Continuation* to D'Herbelot, vol. iv., 4to. edition, 1779.)

PASI'THEA, a genus established by Mr. Lea for some pyramidal shells allied to *Melania*, and placed by him in the family *Melaniana*, found fossil in the tertiary beds at Claiborne, Alabama. (Marine.)

Generic Character.—Shell turrited, sometimes umbilicate; mouth entire, angular above, somewhat effuse at the base; columella smooth, thickened.

Differs from *Rissoa* in having the mouth acutely angular above, and not thickened into a varix. (*Contributions to Geology*, 1833.)

Mr. Totten has described a recent species from the shores of Rhode Island. Operculum horny. (Sill., *Journ.*, vol. xxvi.)

PASITI'GRIS. [TIGRIS.]

PA'SPALUM, so called from one of the Greek names for Millet, is a genus of grasses, which, like some species of Panicum, forms one of the small grains cultivated in tropical countries as food for the poorer classes of the community. The genus is characterised in habit by having a continuous spiked rachis, on one side of which the spikelets are attached. The glume is 2-valved, 1-flowered, closely pressed to the two plane converse paleæ. Seed adhering to the paleæ.

P. scrobiculatum is the *Koda* of the natives of India, and is cultivated by them over almost all parts of India, as it is one of the crops cultivated in the rainy season, when there is great equality of temperature over the whole country. It delights in a light, dry, loose soil, but will grow in a very barren one. The seed is an article of diet with the Hindus, particularly with those who inhabit the mountainous parts of the peninsula, as well as in the most northern parts of the country, or where the soil is barren and unsuited to the cultivation of those grains which are more beneficial. Dr. Roxburgh states that the boiled grain is as palatable as rice. He distinguishes from this another species, which Linnæus called Paspalum Kora, but it appears to be only a variety growing in moist situations. Both species are much relished by cattle either in a green or dry state.

PASQUE FLOWER, or **PASCHAL FLOWER**, so named in consequence of its usually flowering about Easter, is the Anemone pulsatilla of botanists, a little herbaceous plant, with finely-cut leaves, and nodding dull deep purple flowers. It is occasionally met with in the chalky pastures of England, as on the Gogmagog Hills and elsewhere in Cambridgeshire.

PASQUIE'R, ETIENNE, born at Paris in 1529, studied the law under Hotoman, Balduin, Cujas, and other celebrated jurists of that age. After the completion of his studies, it was several years before he could get into practice. In 1564, when the great suit between the Jesuits and the University was brought before the parliament of s, Pasquier was entrusted with the management of the on behalf of the University. [JESUITS.] He made a ant speech, which was printed and translated into various ages, and established his reputation. (*Histoire du Parlement de Paris*, c. 26.) In 1585, Henri III. made Pasquier advocate-general to the Chambre des Comptes. In 1588 he was named deputy to the states-general of Blois, and there he witnessed the murder of the Duke of Guise, which he relates impartially in his letters. When Henry III. was obliged to leave Paris in possession of the League, Pasquier followed him to Tours. His sons were at that time fighting in the king's army, and one of them was killed. After the surrender of Paris to Henri IV., in 1594, Pasquier continued in his office of advocate-general, till 1603, when he resigned, and passed the rest of his life in studious retirement. He died at Paris, in 1615. His works were published in two volumes fol., 'Œuvres d'Etienne Pasquier,' Amsterdam, 1723. They consist of his 'Recherches sur la France,' which is an interesting work, and of his 'Lettres.' The first book of the 'Recherches' treats of the Gauls and their subjugation by the Romans, the invasions of the Franks, the Goths, and the Normans, the origin of the Bretons and the Gascons, and the formation of the Frankish monarchy. The second book treats of the old institutions of the French, of the feudal nobility, the peers, the maires of the palace, the parliaments, &c. The third book relates to the Catholic church, to the bishop of Rome and his gradual assumption of supremacy and of the title of 'pope,' the various conflicts between the see of Rome and the Gallican church, the abuses introduced into the church, the tithes, the benefices, and lastly the 'sect of the Jesuits,' as Pasquier calls it, and here he inserts his 'plaidoyer' against that order. The fourth book treats of the laws and judicial customs of the monarchy. The fifth book consists of remarks on the history of Clovis and his descendants of the first dynasty. The author undertakes the defence of Brunehault against the imputations of the chroniclers. [BRUNEHAULT.] The sixth book relates to the establishment of the third or Capetian dynasty and the history of its kings, their wars both at home and abroad, with some marvellous anecdotes, in relating which the writer shows considerable credulity and want of critical discrimination, which however are not surprising in his age. The seventh book treats of French poetry; and the eighth book, of the origin of the French language, with explanations of many peculiar words and idioms. The ninth book is on the universities and other scientific institutions of France, the introduction of the Roman law, and its prevalence over the 'droit coutumier,' or old prescriptive usages of the country, of which Pasquier shows himself a warm defender, alleging that they were more favourable to the liberties of the nation than the Roman law, which, having emanated from the absolute power of the emperors, was not in accordance with the spirit of the limited monarchy of France; and he presses his views upon several of his brother councillors in some of his letters, and especially in one to Brisson. Pasquier's letters are arranged in 22 books, and relate to multifarious subjects of law, literature, contemporary history, and private life.

Pasquier is an authority of considerable weight in matters relative to the civil history of the old French monarchy before it was converted into a despotism, and the information which he collected has been very useful to subsequent writers. He wrote also poetry, both French and Latin, which has long since been forgotten.

PASQUIN, the name given to a mutilated antient statue which stood at the corner of the palace Santobuono, in a small open place in the city of Rome, near the Piazza Navona. It represents a warrior in the attitude of defence. The subject of the statue is not known. Pasquino was the name of a tailor who lived in that neighbourhood 'many years since,' says Parisio, in his *Antiquities of Rome*, published A.D. 1600. The shop of Pasquino was a sort of place of meeting for the people of the district, who came there to tell or hear the news of the day, as is still the custom in the apothecaries' shops in the provincial towns of Italy. The tailor was a facetious man, and his witty sayings were styled 'Pasquinate,' which afterwards became a common appellation for humourous epigrams and sarcastic lampoons, a kind of composition for which the modern Romans are noted. These lampoons, which often attacked people in high stations and the government itself, were fixed in the night on or near the statue already mentioned; and thus the statue itself came to be called Pasquino, as being the representative of the witty tailor of that name. Collections of these epigrams have been made, and some of them very witty, though often scurrilous and coarse.

PASSAMAQUODDY BAY. [NEW BRUNSWICK.]

PASSAU, the capital of the Bavarian circle of the Lower Danube, is situated at the conflux of the Danube and the Inn, in 48° 34′ N. lat. and 13° 25′ E. long. It consists of the town itself and of three suburbs. The town lies on the peninsula between the two rivers. A handsome bridge, resting on seven piers of granite, crosses the Danube, which is 754 feet wide. On the right bank of the Inn, which is 600 feet wide, is the suburb called the Innstadt, connected with the town by a wooden bridge. On the other side of the Danube, and on the left bank of the Ilz, which there also falls into the Danube, lies the Ilzstadt. The third suburb of Passau is called the Anger. In the angle between the right bank of the Ilz and the Danube there is a rock 390 feet high, upon which stands the fortress of Oberhaus, which is connected with the castle of Niederhaus, situated below it, and surrounded by eight forts. The town of Passau itself is pretty well built; among the public buildings the most remarkable are the palace, formerly the residence of the bishop, the lyceum, formerly a Jesuits' college, the fine cathedral, built of hewn stone, a gymnasium, and an ecclesiastical seminary. There is a military swimming school. In the Domplatz (the cathedral square), the handsomest square in the town, stands the colossal bronze statue of king Maximilian Joseph, erected in 1824, by the inhabitants of the circle of the Lower Danube. The charitable institutions of Passau possess a capital of two millions of florins. There are a great tobacco and snuff manufactory, extensive breweries, tanneries, and paper mills. Passau is the staple town of Bavaria for salt; there are great magazines, to which the salt is brought from the works of Hallein. The inhabitants carry on a considerable trade on the Danube.

In 1552 the Convention of Passau was concluded here, by which complete religious liberty was secured to the Protestants of Germany. Not far from Passau is the Mariahilf Berg, with a chapel, which is a celebrated place of pilgrimage. The bridge over the [illegible], near Passau, is considered a curiosity, being one arch of 200 feet span, the largest in Germany.

Passau was formerly the capital of a bishopric, which was founded in the seventh century, but was secularised in 1803, and in 1805 wholly incorporated with Bavaria. The population is now stated at 10,560, of whom about 7000 live in the town itself.

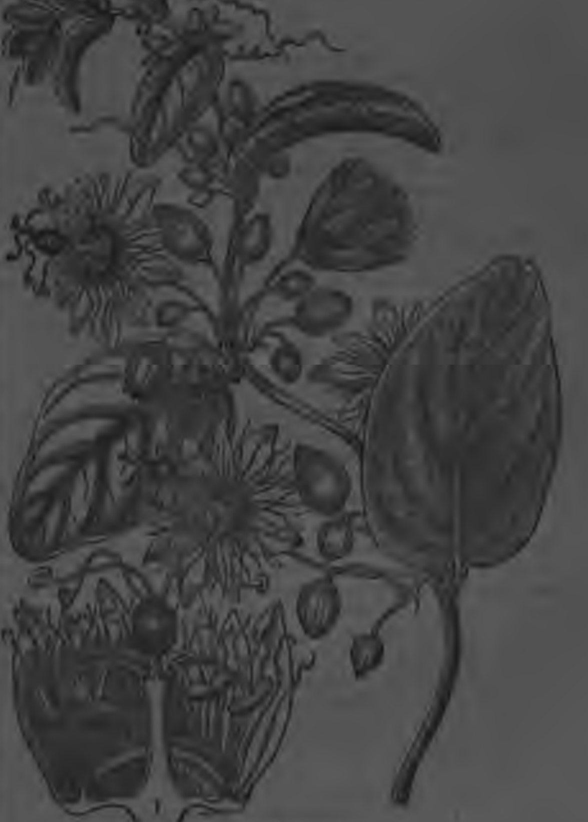
PASSERELLA, Mr. Swainson's name for a subgenus of *Fringilla*, and thus characterised by him:—*Bill* short and perfectly conic, thick at the base, and rather abruptly pointed at the tip, which is entire. *Culmen perfectly straight.* Both mandibles of equal thickness. *Wings* moderate; the first quill shorter than the second, third, and fourth, which are the longest. *Tail* moderate, broad, and nearly even. *Feet* large, strong. *Middle toe longer than the tarsus; inner toe much shorter than the outer.* Claws long, slender, and but slightly curved; hinder claw as long as the toe. America.

Example, *Passerella iliaca*. (Wils., iii., 22, f. 4.)

PASSERITA, Mr. Gray's name for a genus of serpents, *Dryinus* of Merrem.

PASSERONI, GIAN CARLO, born in 1713, at Condamine, in the county of Nizza, studied at Milan in the Jesuits' college, and afterwards took orders as a priest. He went to Rome with the papal nuncio, and afterwards returned to Milan, where he spent the rest of his life in a state of poverty often bordering upon destitution. But he was so used to be content with little, that he felt no uneasiness from his condition, and constantly refused the offers of his numerous Milanese friends to relieve his wants. Passeroni was fond of study, and especially of poetry, and he had a great share in reforming the taste of the Italian writers of his age. Parini, who, in his youth was intimate with Passeroni, afterwards admitted that to his precepts and example he owed the formation of his own style. The principal work of Passeroni is a half burlesque, half moral poem, styled 'Il Cicerone,' in 101 cantos. It is full of digressions, something similar in manner to Sterne's 'Tristram Shandy,' but Passeroni's digressions are clearly intelligible, and have all a moral scope. A kind of parody of Cicero's life is used by the author as a thread whereon to hang his digressions. Passeroni ridicules or reproves the numerous follies and vices of society in a good-humoured and often very amusing strain, and his verses, like those of Ovid, seem to flow naturally and without effort from his genius and facility, and the unaffected simplicity of the style constitute the principal charm of the poem. Passeroni wrote also seven volumes of fables in verse, chiefly imitations of those of Æsop, Phædrus, and Avienus. He died at Milan, in 1803. (Ugoni, *Della Letteratura Italiana*.)

PASSIFLORA, or **PASSION-FLOWER**, is a genus of twining plants, whose name is derived from a fancied resemblance between the parts of their flower and the emblems of our Saviour's crucifixion. In the five anthers the Spanish monks saw his wounds, in the triple style the three nails by which he was fixed to the cross, and in the column on which the ovary is elevated, the pillar to which he was bound; a number of fleshy threads which spread from a cup within the flower, were finally likened to the crown of thorns. 'There are cuts,' says Sir James Smith, 'to be found in some old books, apparently drawn from description, like the hog in armour upon our signs to represent the rhinoceros, in which the flower is made up of the very things themselves.' In reality the flower of Passiflora consists of a calyx and corolla, each of five divisions, consolidated into a cup, from within the rim of which spread several rows of filamentous processes, by some regarded as barren stamens; within these, from the sides of the cup, there proceed one or more elevated rings, notched or undivided, and in various degrees of development in different species, and evidently of the same nature as the filamentous processes themselves. In the centre of the flower stands a column, or gynophore, with the sides of which five stamens are united, but spread freely from it beyond its apex, and bear five oblong horizontal anthers. At the apex of the column is the ovary, a one-celled case, with three parietal polyspermous placentæ, and bearing three club-shaped styles at its vertex. Eventually a gourd-like fruit is produced containing many seeds, each having its own fleshy aril, and usually enveloped in a subacid mucilage.



Passiflora [illegible]

1, a flower cut open vertically, so as to show the calyx, corolla, filamentous crown, interior rings, stalked gynophore, stamens, and ovary.

The genus comprehends a large number of species, chiefly found in a wild state in America, and within or near the tropical parts of that continent. They are all twining plants, often scrambling over trees to a considerable length, and in many cases are most beautiful objects on account of their large gaily or richly coloured flowers. This makes them favourites in gardens, where many are cultivated, particularly the P. alata, quadrangularis, edulis, cœrulea, racemosa, Loudoni, onychina, palmata, and filamentosa, all which are strikingly handsome. It is however chiefly for their fruit that they are valued in the countries where they grow wild, in consequence of the pulp which envelopes the seeds being cool and refreshing, with something of a fragrant bouquet. Under the name of Granadilla the P. quadrangularis is well known in Brazil, where its fruit is as large as a child's head; the water-lemon of the West Indies is the produce of P. laurifolia; P. maliformis bears what is called the sweet calabash; and the pleasant pulp of P. edulis furnishes the confectioner with the most delicate material for the flavouring of ices. Many however are of no value for their fruit, and some are actually fœtid.

The Passion-flower serves as the type of the natural order PASSIFLORACEÆ, of which indeed it constitutes the principal part. This collection of genera is very closely allied to the Cucurbitaceous order, but is distinguishable by its peculiar filamentous crown, and by its superior ovary, exclusive of all other marks. In both cases a few plants are not climbers, and have a dry, not succulent, fruit. The sensible properties of the order are usually too feeble to be appreciable; but when concentrated, as in Passiflora rubra, called 'Dutchman's laudanum,' P. fœtida, and a few others, they are found to be narcotic.

PASSIONE'I, DOME'NICO, born in 1682, at Fossombrone in the duchy of Urbino, studied at Rome, after which he received holy orders, and was employed in several offices under the papal court. He also distinguished himself in classical learning and the study of antiquities, and collected a valuable library of scarce works and MSS. He was a correspondent of Montfaucon and other learned men of his age. In 1706 he was sent by the pope to France, and from thence he proceeded to Holland, where he resided some time. He was appointed papal nuncio to the Congress of Utrecht in 1712, and afterwards to the Congress of Baden in 1714. On his return to Rome from these missions, he resumed his favourite studies, but in 1721 was sent by Innocent XIII. as nuncio to the Helvetic Confederation: he resided in that capacity at Luzern till 1729, when he proceeded as nuncio to Vienna. Passionei wrote a journal of his Swiss mission, entitled 'Acta Apostolicæ Legationis in Helvetia,' 4to., Zürich, 1729. He returned from Vienna in 1738, and was made 'secretary for the briefs' and a cardinal, with the title of archbishop of Ephesus. He was also appointed a member of the Congregation de Propaganda Fidei. Notwithstanding all these duties, he found time to pursue his favourite studies and to keep up an extensive correspondence with Maupertuis, Eckardt, Ruinart, Gronovius, Bianchini, and other learned contemporaries. He had a country-house at Frascati, where he formed a museum. His nephew, Benedetto Passionei, published the inscriptions in this collection, 'Iscrizioni Antiche con Annotazioni,' fol., Lucca, 1765. In 1755 Cardinal Passionei was made librarian of the Vatican. He died at Frascati, in 1761. Passionei was a member of most Italian academies and also of that of 'the Inscriptions' at Paris. He was a great favourite with Pope Benedict XIV., with whom however he had frequent altercations, being very tenacious of his opinions and not at all courtly disposed. He was particularly hostile to the Jesuits, and was very careful not to admit any of their works into his library. His books were purchased after his death by the Augustin monastery, and added to their fine library, which is styled the 'Angelica,' and is one of the principal public libraries at Rome. Passionei revised, together with Fontanini, the 'Liber Diurnus Pontificum,' edited several other works, and wrote in Italian a funeral panegyric on Prince Eugene. He was a great promoter of learning, and one of the most distinguished prelates of the church of Rome in the last century.

(Galletti, *Memorie per servire alla Storia della Vita del Cardinal Passionei*, Rome, 1762.)

PASSIVE VOICE. [MIDDLE VOICE.]

PASSOVER (פֶּסַח, *a passing over*, or *sparing*, *πάσχα*), also called the feast of unleavened bread, one of the three great annual festivals of the Jews, was established to commemorate God's passing over the houses of the Israelites in Egypt when he slew the first-born of the Egyptians (*Exod.* xii. 27). It was first observed in Egypt on the night before the Exodus. It began on the evening after the 14th day of the month Abib, or Nisan, which was the first month of the sacred year, and lasted seven days, the first and last of which were observed as especially holy by abstinence from all labour, and by a convocation of the people for worship. After the settlement of the Israelites in Palestine, it was incumbent on all their males to go up to the Temple to keep this feast. The following were the ceremonies observed in its celebration:—A lamb, or kid, a male of the first year, without blemish, was selected by each household (or if the households were small, by two conjointly) on the 10th day of the month, and it was kept till the 14th day of the month, when it was killed in the evening (literally, 'between the two evenings,' an expression which is variously interpreted), and roasted, and eaten with unleavened bread and bitter herbs. None of it was to be left till the next day. that was not eaten was to be burnt. They were to eat in haste, standing, with their loins girt, their shoes on their feet, and their staves in their hands, as those prepared for a journey. None, whether Israelites or strangers, were to partake of it unless they had been circumcised. Not a bone of the paschal lamb was to be broken, and all of it was to be eaten in the same house. When the lamb was killed its blood was sprinkled with a bunch of hyssop on the lintel and door-posts of the houses, which was intended, in the original institution of the feast, as a sign to distinguish the houses of the Israelites from those of the Egyptians, and no one was to go out of doors till the morning.

During the seven days for which the feast lasted nothing but unleavened bread was to be eaten, on penalty of being cut off from the people. Sacrifices were appointed to be offered on each of the seven days (*Numb.* xxviii. 17…). On the second day of the feast a sheaf of corn was to be brought, as the first-fruits of the harvest, and the priest was to wave it before the Lord (*Levit.* xxiii. 10; Joseph., Ant. iii. 10, 5).

The word passover is used not only for the feast, but also repeatedly for the paschal lamb itself.

This institution was typical of the death of Christ for the salvation of his people (1 *Cor.* v. 7).

(Winer's *Biblisches Realwörterbuch*, under 'Pascha;' Lightfoot's *Temple Service*, c. 12.)

PASSPORT, a printed permission signed by the secretary of state of the home department of a country, which allows a subject of that country to leave it and go abroad. When he has obtained this, the bearer must have his passport signed by the minister or agent of the state to which he intends to proceed. A foreigner who wishes to leave the country where he has been residing, generally obtains a passport from the minister or agent or consul of his own state. Such a document states the name, surname, age, and profession of the bearer, and serves as a voucher of his character and nation, and entitles him to the protection of the authorities of other countries through which he may pass, and which are at peace with his own. On arriving at the outports or frontier towns of a foreign state, every traveller is obliged to show his passport, which is examined by the proper authorities before he is allowed to proceed on his journey. This ceremony is sometimes repeated at every garrison town which he passes on the road. Even the natives of most European states cannot travel twenty miles through their own country without being furnished with a passport.

The system of passports is old, but it has become much more rigid and vexatious during the last half century. The only civilised countries in which passports are not required are the British Islands and the United States of North America; and the natives of those two countries, accustomed to the freedom of unobstructed locomotion, find the regulations as to passports when they travel on the continent of Europe to be rather irksome. The practice has been defended on the plea that it prevents improper and dangerous persons from introducing or concealing themselves; but numerous instances have proved that persons, however obnoxious, who have money and friends, can evade such restrictions. That every state may admit or refuse admittance to foreigners as it thinks fit, cannot be questioned; and in times of war especially, some sort of restriction may be required for the safety of the country; but the present vexatious system of passports, as enforced in many European states in time of profound peace, is both illiberal and puerile. It is a tax upon travellers, to whom it causes much trouble and loss of time, while the advantages supposed to result from it are at least very dubious. It has been compared to spiders' webs, in which flies are caught, but which larger insects or birds easily carry off along with them. In Turkey a passport is called a FIRMAUN.

PASTES. [GLASS, p. [illegible].]

PASTO. [GRANADA, NEW.]

PASTOR (Ornithology). [STURNIDÆ.]

PASTORAL (from the Latin *pastor*, a shepherd or herdsman), is the name given to poems which are descriptive of the pursuits of country life, or to dramas in which the characters represent shepherds or other country-people. [BUCOLICS; IDYLL.]

Pastoral letters are circulars addressed by a bishop to his diocesans for purposes of religious instruction or admonition in matters of discipline. This name also is derived from 'pastor,' the bishop being styled the shepherd of his spiritual flock.

PASTURE LAND. There are tribes which have no other occupation than that of pasturing domestic animals, and immense tracts of fertile soil are still unappropriated to any definite owner. Where the climate is genial, and the extremes of heat and cold are unknown, cattle are fed all the year round by moving from one place to another. In such a state are some of the wandering tribes of Asia, who have no fixed habitations, but pitch their tents wherever pasture is abundant, and move them to another spot as soon as it is consumed where they are. In civilised countries, where the land is divided and appropriated, such a system cannot exist; though there are still traces of it in this country, as we see in the few remaining waste lands, on which there is a right of common.

The pasturage of cattle is now a part of regular husbandry; the land which affords the herbage for cattle forms part of private possessions, and a rent is paid for its use. This has introduced a new system. Pastures are now fenced and protected, and pains are taken to improve them, so as to maintain many more cattle or sheep than they would in their natural state. We shall not here speak of rich grass lands, in which bullocks and sheep are fatted, and which are commonly called grazing land: nor of artificial pastures, which form portions of arable farms, and have been depastured only to enrich them and make them more fit to produce corn when again submitted to the plough. But we shall consider those tracts of land which, from situation, climate, or other causes, although they are portions of certain estates and the property of individuals, lie nearly in a state of nature, and produce a revenue or profit only according to the number of cattle and sheep which can be reared or maintained in them. Such are the rich pastures on the Jura, the Alps, and Pyrenees, too high and exposed to allow of cultivation or permanent habitation, but producing abundant food for cattle in particular seasons of the year. The Jura and the Alps, which are best known to English travellers, contain very rich pastures for cows, and give a considerable return in butter and cheese. The snow which covers these mountains for a considerable part of the year, protects the herbage; and the moisture which prevails in the summer by the continued passage of clouds, which appear in the form of heavy fogs to those who are enveloped in them, keeps up a luxuriant vegetation of the small Alpine plants which form the richest pasture.

Whenever pastures are hired, the rent is always reckoned, not by the extent of surface, but by the stock which can be maintained upon it. Thus, in Switzerland, the mountain pastures are divided into portions of 20, 40, or more cows. In Scotland they reckon sometimes by the number of bullocks which can be reared, and sometimes by the number of sheep which can be kept. This mode of reckoning is much fairer than by mere extent of surface. In many places pasturing has been found much more productive than cultivation; and some large proprietors have converted great tracts of land from arable into pasture farms. But this can only be done where the population is very scanty, and where the soil and climate do not tempt men of capital to settle.

Considerable improvements have been made in natural pastures, not only by the raising of banks and stone walls as shelter against the winter's storms, but also by extensive draining and clearing the surface of wild plants and shrubs, which prevent the herbage from springing up, and greatly diminish the food. On the sides of steep hills, where springs are apt to break out and produce bogs and swamps, drains judiciously made have carried off the water and laid dry the pastures below them; while reservoirs have been constructed in many places to receive the water and to supply the stock in dry weather. On peaty moors the application of lime to the surface has often produced wonderful effects, and made various kinds of clover and grasses spring up which were never seen on the spot before.

Those who are possessed of extensive pastures often look upon them as of too little value to lay out any money in their improvement; and unless when an attempt is made to bring them into regular cultivation, which often fails after a great outlay of money, they are not thought worth any attention. Yet many rough hilly pastures might be doubled and tripled in value merely by clearing the surface, burning coarse grasses, rushes, ferns, and furze; and sowing a few seeds where the ashes have been spread. The additional number of cattle or sheep which can be maintained by this means, would surprise any one who had not had experience of such improvements. The forming of convenient channels for the water to run off is another important object, which can often be effected at a trifling expense; and a loose surface laid dry by this means may be much improved, by merely burning the heath which grows upon it. After the fire has scorched the ground, grasses will spring up spontaneously; and, at a very small expense, a considerable tract of mountain pasture may be converted from the state of a brown heath or moor to that of a fine green sward.

Wherever there are large pastures, proper and suitable buildings made of substantial materials should be erected. The cattle should have numerous sheds for refuge in bad weather, and sheep especially should have protection and shelter. Warmth is in some cases of more importance than food; and an animal exposed to all the severities of a northern climate requires more food to keep him alive, than when he is kept warm and protected from the immediate influence of cutting winds.

There is another kind of pasture in England on the chalky hills which are called downs, where useful and hardy sheep are reared. Here the exposure is less, and the proximity to the plains gives frequent opportunity of driving the sheep to sheltered situations. The grass on the chalk hills is in general very fine and short, and the quality is very good. The soil is only a few inches deep, but it has been enriched by the dung and urine of sheep from time immemorial. Attempts are made occasionally to convert some portions of these pastures to tillage: but it is not often an advantageous speculation. A few crops may be obtained at first; but the thin layer of rich earth, which is at the surface, is soon exhausted, and nothing remains but barren chalk. No art can restore the fine turf which had been produced by ages of pasturage.

To those who have extensive pastures it is of great consequence to ascertain whether oxen, heifers, cows, or sheep are the most profitable, and of these, what breeds suit the situations; and, when this has been determined by experience, to know what quantity may safely be kept, without suffering for want of sufficient food, or allowing any portion of the pasture to wither or become coarse from not being duly fed off. Whatever be the stock depastured, the greatest attention should be paid to them by a herdsman or shepherd of experience, who should have a certain number only under his care. It is a good plan to give him some share or interest in the produce as part of his wages. When any part of the stock is sold off to drovers or butchers, he should have a per centage on the sale. This will give him the activity of an owner, and he is not so likely to be negligent and allow the stock to suffer from a want of sufficient food, or from accidents which can be prevented by proper attention.

Very poor pasture on sandy or gravelly loams is of very little value to the proprietor; where the situation allows of such land being converted into plantations, it will generally be found most advantageous to do so, but if there are means of improving them by ploughing, liming, and manuring, they may often be converted into good arable farms. A great part of Norfolk, which now bears excellent crops of barley, wheat, and clover, was once only poor sandy pasture, where the chief income to the proprietor arose from rabbit warrens. We must not always judge of the capabilities of a soil by the natural grasses which grow upon it, before it has ever been stirred and cultivated. When loamy sand or gravel is left in a hard condensed state, it will bear very little, but when it has been broken up deep, and trenched and improved by lime and manure, it becomes very useful land. The same may be said of cold wet pastures on a stiff clay. The water checks the roots of the better sort of grasses, and nothing thrives in such pastures except rushes and very coarse aquatic plants; but when they have been carefully drained—when the surface has been pared and burnt, and the ashes spread over the land—a very material improvement takes place, whether it be left unbroken, to produce herbage, or be improved by a course of judicious cultivation, and laid down again to grass in a clean and fertile state; in either case, the pasture, from being of little use, and perhaps dangerous for sheep, which are apt to rot there, becomes sound and good, producing excellent nutritious herbage, and will continue so ever after.

When the soil is naturally deep and of a good quality, but the situation renders it not advisable to convert the pastures into permanent arable land, and the herbage has been deteriorated and overrun with moss or weeds, it is a very effective mode of improving the pasture to plough up the sward as thin as possible, and then, having removed the sods into heaps or rows, to plough and scarify the bared surface to the depth of four or five inches, so as to give it the appearance of a fallow field. When it is well pulverised and harrowed level, the sod, which had been taken off, is chopped into small pieces by the spade, and scattered over it; and after a shower has somewhat moistened the surface, it is well rolled with a heavy roller. Thus the moss is effectually destroyed: the root-weeds have been eradicated, and the fine grasses, the roots of which are short and fibrous, are preserved. They will soon strike into the loosened soil, and a fine close sward will be the result. The improvement is still greater if lime is put on the land before the spreading of the sods, and if at the same time some of the best grass seeds are sown over it. The proper season for this operation is after harvest, and no cattle should be admitted till the next spring.

Pastures are seldom improved with manure, which is generally reserved for arable land, or grass land intended to be mown for hay: but if richness is valuable in a pasture, it will well repay the expense of manuring, especially with liquid manure, the drainings of dunghills and the urine of cows and horses, which is collected in a tank when they are kept in stalls. Peat ashes are also very useful, and have a powerful effect in stimulating the vegetation of all the grasses. Saltpetre and nitrate of soda are said to have the same effect. When it is intended to convert land which has been in a state of heath or waste, covered with fern, brambles, ling, and other coarse plants, into good pasture, it is indispensable to begin by a course of arable cultivation; and it is only when the soil has been brought into an improved state by tillage and manuring, and all the roots and seeds of noxious plants have been eradicated, that grass seeds may be sown with any prospect of obtaining a good sward. Most of these soils are poor and sandy, and not very favourable to the growth of good grass. In this case the safest mode of converting the land into pasture is by inoculating it with pieces of sods taken from a good rich pasture. [GRASS LAND.] By this means, and subsequent depasturing with sheep only, very good pastures have been produced on very poor soils; and if in the course of a few years they should degenerate, they may be profitably broken up and cultivated on the convertible system of husbandry, after which they may again be laid down for a certain number of years. Wherever the soil consists of a sandy or gravelly loam, this system is the most advantageous.

In the richest pastures, such as those of Lincolnshire and other grazing counties, an acre will maintain and fatten an ox of 80 or 90 stone, and sometimes keep several sheep in store order besides. There is a marked difference between land that will fatten an ox, and that which will only rear him. This can scarcely be discovered by simple examination of the land; but is found by experience. The same appearance of grass has more *proof*, as it is called, in one place than another. The bite may be very short and the pasture appear bare, and yet the value of it may be seen on the ribs of the cattle. Much of the skill of a grazier consists in stocking his pastures to advantage. He should know the power of every portion of it, and stock it so that the grass may not grow faster than it can be cropped by the cattle or sheep, and that the animals may always have the full quantity required. Every animal wants a certain quantity of food to repair the daily waste occasioned by the animal functions. If he has no more, he makes no progress: the more he can convert into flesh and fat beyond this quantity in a given time, the more profitable he will be. Hence the superior qualities of some animals with respect to this point indicate the superiority of their breed, and afford the greatest net profit to the grazier. In the same pasture one beast or sheep will give a reasonable profit, while another may occasion an actual loss. The adaptation of the stock to the nature of the pasture is consequently an object of the greatest importance, and requires much judgment and experience.

PASYTHEA, the name given by Lamouroux to a group of Linnean Sertularidæ. [POLYPIARIA MEMBRANACEA.]

PATAGONIA, a country in South America, comprehending the most southern portion of that continent. It includes all those parts in which the Europeans have not formed settlements, or to which they do not lay claim. A few years ago the state of Buenos Ayres extended its settlements to the Bahia Blanca (39° S. lat.), and the federal government of the provinces of La Plata has fixed the southern boundary of the federal republic on the banks of the Cusu Leubu, or Rio Negro. This river therefore must now be considered as the dividing line between Patagonia and the provinces of La Plata, though a great extent of country north of that river is still the undisputed abode of wandering aboriginal tribes. From this new boundary, the most northern point of which is near 38° 50′ S. lat., Patagonia extends southward to the Strait of Magalhaens, by which it is divided from the Antarctic Archipelago commonly called Tierra del Fuego. The most southern point of the South American continent and of Patagonia is Cape Froward, near 53° 55′ S. lat. and 71° 25′ W. long. On the east Patagonia is washed by the Atlantic, and on the west by the Pacific Ocean. The line which divides it from Chili is not quite determined, but it is supposed that it is formed by Reloncavi Sound and Reloncavi Inlet (between 41° [illegible] and 42′ S. lat.), which constitute the innermost recess of the Gulf of Ancud, which separates the island of Chiloe from the continent. Farther north the Andes constitute the boundary up to 40° S. lat. According to a rough estimate, the area of Patagonia exceeds 276,000 square miles, or is about 72,000 square miles more than that of France.

Patagonia comprehends two regions, which differ from one another in nearly every respect—the mountain-region and the plains. The mountain-region occupies the countries extending along the shores of the Pacific and the western portion of the Strait of Magalhaens. The plains occupy the eastern part of the country, stretching out along the Atlantic and the eastern part of the Strait of Magalhaens.

The mountain-region comprehends the southern portion of the Andes. This extensive mountain-chain begins near 52° 10′ S. lat., on the northern shores of the inlet called Ancon sin Salida, or Sound without Outlet. That portion of the mountain-region which is south of that inlet may be considered as an appurtenance of the chain, but not as constituting a portion of it, for it is divided from it by a deep arm of the sea, and also intersected by another channel. It is a remarkable and characteristic feature of the southern part of the mountain-region of Patagonia that it is cut through by two long but comparatively narrow inlets, which extend to the plains east of the mountains, and there expand into large salt-water lakes. The southern of these lakes or inland seas may be compared to the Mediterranean, as it consists of two basins united by a narrow channel of moderate extent, and connected with the Strait of Magalhaens by a strait of larger dimensions. The last-mentioned strait, called Jerome Channel, branches off from the Strait of Magalhaens near 53° 35′ S. lat. and 72° 30′ W. long., and extends northward with a slight bend to the west to 53° [illegible], where it turns north-east, and gradually widens into Otway Water. It is upwards of 30 miles long, and generally [illegible] miles wide. Otway Water, the southern of these inland sea-basins, extends towards east-north-east, and increases in width as it proceeds eastward. Near Jerome Channel it is hardly six miles wide, but towards its eastern extremity above twenty. Its length is probably 50 miles; the eastern extremity however has not been explored. The navigation of this inland sea is dangerous, even for large boats, on account of the strong tide-currents and gales. Not far from the north-eastern extremity of Otway Water, a narrow winding channel runs north by west to another inland sea-basin. This channel is called Fitzroy Passage, and the basin Skyring Water. Fitzroy Passage is about eight miles long, and [illegible] anywhere above half a mile wide, but it has depth enough for the largest vessels. It enters Skyring Water at its [illegible] eastern extremity. The last-mentioned inland sea basin extends from the northern entrance of Fitzroy Passage [illegible]ward about 50 miles in length, varying in width between

8 and 12 miles. It contains a number of rocky islands, among which that called Dynevor Castle rises to a considerable elevation.

The southern inland sea in form bears some resemblance to the Baltic. The main body is of comparatively small extent, but it sends out several branches, which advance to a considerable distance inland. This sea has not yet received a general denomination, and we shall name it Kirke Water, to commemorate the exertions of a seaman in the exploration of this basin. From Smyth Channel, which divides Queen Adelaide's Archipelago from the continent of South America, near 52° 10′ S. lat., a long and crooked strait branches off to the east, which is called Ancon sin Salida, and extends between high mountains about 30 miles from the shore in a straight line, when it opens into Kirke Water, a basin about 30 miles long, and on an average eight wide. This basin extends first north-north-east, but afterwards it turns to the east. From this main body of the basin two deep inlets branch off, one towards the north and the other southward. Each of them is above 20 miles long, and they vary from one to three miles in width. The northern, called Last Hope Inlet, turns to the west-north-west, and terminates about six miles from the shores of the Pacific; the southern, called Obstruction Sound, which at its extremity bends to the south-west, is there only about six miles distant from Skyring Water, but separated from it by high ranges of hills. A deep and narrow inlet runs northward from the strait which unites this basin to the ocean, intersecting the country between the ocean and Last Hope Inlet for nearly 30 miles from the Ancon sin Salida. It is called the Canal of the Mountains.

These three inland seas, Otway Water, Skyring Water, and Kirke Water, lie properly within the mountain-region of Patagonia, but their eastern extremities border on the eastern plains, being bounded only by ranges of flat low hills. Thus the southern portion of the mountain-region consists of two isolated districts. The more southern of these districts, which is enclosed on three sides by the Strait of Magalhaens, and on the north by Otway Water, is called Brunswick Peninsula, and is connected with the main body of Patagonia only by the isthmus which extends from the eastern shores of Otway Water to the Strait of Magalhaens, opposite Elizabeth Island. This isthmus is from seven to ten miles wide, and, as far as our knowledge goes, low, and partly occupied by lakes. The shores of Brunswick Peninsula have been examined with unusual care along the three sides where it is washed by the Strait of Magalhaens, and laid down with great accuracy. Still it does not appear that a stream above the size of a mountain-torrent finds its way to the strait itself. This seems rather strange, when we consider that the area of the peninsula probably exceeds 1000 square miles. The whole drainage therefore must run off northward to Otway Water, which is owing to the singular disposition of the highest ground of this tract. South of the isthmus which divides Otway Water from the Strait of Magalhaens, a range of hills, called Brecknock Hills, rises to from 1000 to 1200 feet, and is only a few miles from the strait, and parallel to it. In proceeding southward in that direction it rises into mountains, covered with snow, and consequently more than 3000 feet above the sea-level. Where the mountains approach Cape Froward they sink under the line of perpetual congelation, but Mount Tarn is 2600 feet high, and the mountains at the back of the Cape are estimated at 2500 feet. It appears that the mountains continue close to the shore of the strait farther west-north-west to the entrance of Jerome Channel, and then north-north-west and northward along the last-mentioned channel to the place where Otway Water opens to view. This latter range seems less elevated, as the highest summit, Mont Cont, near Port Gallant, is only 2000 feet high. What is the character of the country enclosed by this nearly semicircular range, we do not yet know. It does not appear to contain high mountains, for if such existed, they would have been seen when Captain Fitzroy took a view of the country from some hills near Fitzroy Passage. There are reasons for supposing that this country may turn out to be fit for cultivation. Captain King observes that the southern shores of this peninsula, though extremely rocky, are distinguished by luxuriant vegetation, and that the trees attain there a full growth, while farther west they are stunted. The climate, though colder than in Europe at an equal distance from the pole, is not subject to extreme cold. The greatest disadvantage is the moisture of the atmosphere and the frequent rain, which is owing to the peninsula being open to the winds from three quarters of the compass. But as the interior of the peninsula is sheltered from these winds by the surrounding mountains, it probably partakes much less of this continual moisture than the shores of the strait.

The tract of country, or rather peninsula, which is enclosed by Otway Water, Fitzroy Passage, Skyring Water, and the western portion of the Strait of Magalhaens, is called Ponsonby Land. The eastern part of it contains low wooded tracts of considerable extent along the shores of both waters, but the interior is occupied by hills, rising to about 1500 feet, with the exception of one summit, Mount Misery, which is near 72° W. long., and attains an elevation of about 2000 feet. It rises above the line of trees, but does not attain the snow-line. The western portion of Ponsonby Land is covered with rocky mountains. On Croker Peninsula and the adjacent district they do not appear to attain a great elevation. But on the shores of Skyring Water, west of 72° 30′, several of them rise above the snow-line and send down extensive glaciers on their slopes towards the sea. These high snow-capped mountains continue across the narrow isthmus which divides Skyring Water from Beaufort Bay, and attain their greatest elevation in Mount Burney, which is situated not far from the southern shores of the Ancon sin Salida, and is 5800 feet high. Thus we find that between 52° and 53° 30′ S. lat. the highest part of the mountain-region is nowhere more than ten miles from the shores of the Pacific, and frequently much nearer. Farther eastward the mountains decline in height, and are intersected by level tracts of some extent, until they disappear in the plains of eastern Patagonia, about 40 or 50 miles from the Pacific. This is especially observable on Kirke Water, the eastern shores of which, as well as those of Obstruction Sound and Last Hope Inlet, are low, and at some distance only exhibit some broad-backed hills of moderate elevation and extent. A tract of similar character was observed along the eastern part of the northern shores of Skyring Water.

The Andes, that elevated chain which traverses South America in its whole length, begin on the south, on the very shores of the Ancon sin Salida (52° 10′ S. lat.). The narrow inlet called the Canal of the Mountains, which runs nearly 30 miles, is enclosed on both sides by a range of steep mountains, broken here and there by deep ravines filled with frozen snow, and surmounted by extensive glaciers, from which huge avalanches frequently descend. These two ridges unite on the isthmus between the Pacific and the north-western extremity of Last Hope Inlet, and at this point the mountain-mass of the Andes does not appear to be more than ten miles wide. As the summits are always covered with snow, they probably exceed 4000 feet in elevation. The mountains continue northward close to the shores of the sea, so as to leave no level ground along the beach. It seems that the higher part of this range is always covered with snow, at least the inlets of St. Andrew's Sound (50° 30′ S. lat.) are closed at their extremity by immense glaciers. In this part the range seems to be about 40 miles wide, and on its eastern edge is situated Mount Stokes, 6400 feet above the sea-level. North of 50° S. lat. the mountain range seems to preserve a general width of forty miles, and the whole of this space seems to be occupied by mountains rising above the snow-line, or approaching it. They terminate on Messier Channel, which separates Wellington Island from the continent, in very high and precipitous rocks, which extend as far as 48° 30′ S. lat., and are frequently dotted with glaciers at the extremities of the inlets which penetrate the rocky masses. Between 48° 30′ and 47° S. lat. no snow-capped mountains are discovered near the coast, and it is not known, though it is probable, that they occur farther inland. The coast is hilly, but neither precipitous nor very high, and in many places there is much low and thickly wooded land. North of 47° S. lat. opposite the peninsula of Tres Montes some snow-covered mountains and glaciers again approach the sea. The peninsula itself consists of high rocky masses, connected by other rocks, which constitute the isthmus of Ofqui, with the snow-capped mountains lying farther east. Between 47° and 46° S. lat. is the volcano of S. Clemente, the most southern of the volcanoes of the Andes. North of the peninsula of Tres Montes, the highest portion of the Andes again comes close to the shores of the Pacific, and the most elevated summits are covered with perpetual snow, which in this latitude in summer seems to descend to 5000 feet above the sea-level. Mount Meli-moya, near 44° is about 8000 feet high. Three volcanoes in this range are visible from the island of Chiloe, the Yntales, 6725 feet high, the Corcovado (hump-backed) 7510, and the Minchinmadiva, 7046 feet. All these high summits are situated in the range which rises close to the shores of the Gulf of Ancud. We are not acquainted with the width of the Andes in this part. From the Strait of Magalhaens to 41° 48′ S. lat. the Andes constitute the very shores of the Pacific, and the watershed between the two oceans is so near the western coast, that the largest river which flows into the Pacific has its origin only 13 miles from the beach. This is the Rio S. Tadeo, the mouth of which is a little south of the peninsula of Tres Montes. The shores along this extensive coast-line are rocky and high, with the exception of a few places of very moderate extent. But there is a difference between those which are north of the peninsula of Tres Montes and those which are south of it. The former run nearly in a straight line, both the projecting rocks and the recesses between them hardly anywhere exceeding one mile in extent. But south of the peninsula the inlets penetrate many miles into the mountain-masses, and thus form huge promontories. The farther we advance to the south, the more the inlets increase in depth, until we reach the Ancon sin Salida and the Jerome Channel, which extend across the whole mountain-region.

But the open sea of the Pacific does not wash this rocky coast. A series of high and rocky islands lie like a barrier in front of it, so that no part of the continent, except the peninsula of Tres Montes, is exposed to the ocean's swell. Some of these islands are of great extent; others are only separated from one another by narrow straits, which are not visible at some distance from the open ocean, and the islands accordingly appear to be a continuous high rocky shore. The most northern is the island of Chiloe [CHILOE], between which and the continent is the Gulf of Ancud. This island is separated from the Chonos Archipelago, which lies farther south, by a channel nearly 20 miles wide. The Chonos Archipelago occupies the space between 44° and 46° S. lat., and consists of numerous islands, some of which are of considerable extent: they are divided from one another by narrow straits, and the sea between them and the continent is full of cliffs and rocks. Then follows the peninsula of Tres Montes, which is nearly isolated by a deep bay that enters the continent from the north, and extends about 30 miles southward. South of the peninsula is the Gulf of Peñas, which contains only scattered islands; but near 47° 30′ S. lat. is the small group of the Guaianeco Islands, followed by Wellington Island, which extends from 47° 50′ to 50° S. lat., and in some parts is 60 or 70 miles wide. It is however conjectured that the northern and western parts of this extensive island are divided into several smaller islands by narrow channels. The long strait which separates Wellington Island from the continent, and is called Mesier Channel, is on an average two miles wide towards each extremity; but in the middle, and for a length of about 40 miles, it is hardly a mile wide, and in three particular places not more than 400 yards wide. A broad channel, called the Gulf of Trinidad, separates Wellington Island from the Archipelago of Madre de Dios. This archipelago, which is little known, is separated from the continent and Hanover Island by Concepcion Strait. Hanover Island extends nearly a degree north and south, but it is not ascertained whether or not it consists of several islands. The strait south of this island, called Lord Nelson's Strait, separates it from the archipelago of Queen Adelaide, an assemblage of islands which run more than 80 miles north-west and south-east: only a small number of them have been surveyed, namely, those which lie contiguous to Smyth Channel, which separates the archipelago from the continent, and those which constitute the northern shores of the Strait of Magalhaens, which strait lies between them and South Desolation Island. [MAGALHAENS, STRAIT OF.] These islands are, without exception, high and rugged, and have a rocky shore; but the mountains in none of them rise to the snow-line, except on South Desolation.

The interior of this region is almost entirely unknown, but we have some information respecting the climate of the coast and the islands. The difference of geographical position between the two extremes being fourteen degrees, one would expect to find a greater difference in the tempe'ure than really exists. On the island of Chiloe the m temperature of the winter seems to be 45°, and that of the spring 50°, or somewhat more. It is probable that the mean annual temperature is as high as that of London, for though the summer-heat is less, the cold is not so great in winter, and ice is never formed in the low country. Mr. Darwin has compared the temperature of Port Famine, on the Strait of Magalhaens, at the other extremity of the mountain-region of Patagonia, with that of Dublin, in the following table:—

	Lat.	Summer temper.	Winter temper.	Difference.	Mea
Dublin . .	53° 21′ N.	59°.54	39°.2	20°.34	49°.
Port Famine .	53 38 S.	50	33°.08	16°.92	41°
Diff.	0 17	9°.54	6°.12	3°.42	7°

It would therefore appear that the difference in the mean annual temperature between S. Carlos in Chiloe and Port Famine does not exceed ten degrees of Fahrenheit, and we do not think that a country of similar extent can be pointed out on the surface of the globe where such a small difference in temperature occurs. This phenomenon is due to the great dampness of the atmosphere. As the prevailing winds blow from the west, they bring to the land the moisture which they collect in passing over the wide expanse of the Pacific; and this moisture being suddenly condensed when it comes in contact with the high mountains along the shores, descends in abundant and nearly continual rain. In Chiloe fine weather alternates with heavy rain from September to March; but in the other six months a day seldom passes without abundant rain. On the peninsula of Tres Montes only two or three weeks in November are without rain, and farther south there is hardly a day without either rain or snow and sleet, according to the seasons. North-west winds prevail, and bring clouds and rain in abundance: strong south-westers succeed them, and partially clear the sky: the wind then moderates, and hauls into the south-east quarter, where, after a short interval of fine weather, it dies away. Light breezes spring up from the north-east, freshening as they wear round to north, and augment the store of moisture which they always bring. From the north they soon shift to the usual quarter, north-west, and between that point and south-west they shift and back sometimes for weeks before they take another turn round. It never blows hard from the east, rarely with any strength from north-east, but sometimes from south-east, especially about the middle of winter (from June to August). The north-western gales are sometimes so furious that the houses are not secure, and the largest trees are torn up by the roots. In summer southerly winds last longer and blow more frequently than in winter.

The constant dampness of the air, though not favourable to many European plants, especially to fruit-trees, maintains a vigorous vegetation. The forests, which cover the sides of the mountains for two-thirds of their height north of 45° S. lat., rival in luxuriance those of the tropical regions. Stately trees, with smooth and highly coloured barks, are covered with parasitical plants; large and elegant ferns are numerous, and arborescent grasses twine round the trees to the height of 30 or 40 feet. South of 45° S. lat. vegetation is less vigorous; but even at the most southern extremity, on the Strait of Magalhaens, the country and hills, from the height of 2000 feet above the sea to the very verge of high-water-mark, are covered with trees, mostly evergreens, and some large enough to be used as timber, as the evergreen beech (Fagus betuloides), and two other species of beech. Capt. King saw large and woody-stemmed trees of Fuchsia and Veronica, in England considered as tender plants, in full flower within a very short distance of the base of a mountain covered two-thirds down with snow, and this with a temperature of 36°.

Where the mountains border on the eastern plains, a kind of deer, with short straight horns, is abundant. There are also pumas as far south as 53° S. lat., cavias, and nutrias; seals, otters, fur-seals, and sea-elephants. Fish is very plentiful, especially several smaller kinds, which live in the subaquatic forests formed by the gigantic sea-weed (Fucus giganteus of Solander), which covers all the rocks near the open coast and in the numerous straits. Land-birds are not numerous, but water-fowl abound, among which there is the black-necked swan (Anser nigric… and several kinds of geese and ducks. Shell-fish of several kinds occur in the recesses of the inlets, and they constitute the principal food of the inhabitants during a part of the year. On the Guaianeco Islands and the Chonos Archipelago the potato grows wild. The largest dug up on an island of the last-mentioned archipelago measured two inches in length and an inch in thickness: they were quite tasteless.

The plains of Patagonia, which occupy the greater portion of the country, extend along the Atlantic Ocean. The line which separates them from the mountain-region is only known south of 49° S. lat.: it begins on the shores of the Strait of Magalhaens at Cape Negro (53° S. lat. and 70° 50′ W. long.), and thence runs west-north-west to the north-eastern extremity of Otway Water, follows the channels of Fitzroy Passage and the northern shores of Skyring Water to 72° W. long., and then extends along the eastern shores of Obstruction Sound, Kirke Water, and Last Hope Inlet. It leaves the last-mentioned inlet near 71° W. long., and runs due northward to Mount Stokes and Lake Viedma (49° S. lat.). Farther north the boundary-line is not yet known.

These plains, though similar in aspect, seem nevertheless to differ in their natural capacities. Between 47° and 48° S. lat. the coast forms a wide promontory, projecting near 100 miles from the body of the mainland. On this promontory, or, to speak more precisely, at the back of Cape Blanco, are the high lands of Espinosa, which are visible from the sea. They rise at least 4000 feet above the sea, and form a range of an irregular form with several peaked summits. It is not improbable that this range extends westward until it joins the Andes. On this promontory and the contiguous coast, as far north as 45° S. lat. and southward to 49° S. lat., the rocks are porphyritic, but they seldom rise more than 300 or 400 feet above the sea-level, when they stretch westward in an undulating plain, which is covered with a light sandy soil, through which the rock protrudes in many places. This tract is dry and parched, and has no vegetation except a few tufts of grass and here and there a straggling bush of barberry or of a dwarf woody shrub which supplies good fire-wood. There is no water. This tract is frequently traversed by the native tribes, but they never seem to stay there for any length of time.

South of 49° S. lat. to the northern shores of the Strait of Magalhaens, the coast presents an aspect similar to that of the county of Kent in England, but instead of chalk, the cliffs are composed of soft marly clay, without any gravel or impression of organic remains. Between the high and low tide mark, there is a smooth beach of green clay hardened by the action of the surf to the consistence of stone, which extends about a hundred yards into the sea, and is succeeded by a soft green mud, over which the water gradually deepens. The outer edge of the clay forms a ledge parallel to the coast, upon the whole length of which the sea breaks with violence. The sea-beach between the high-water mark and the cliffs is narrow, and consists of shingle with scattered masses of green indurated clay. The cliffs themselves rise rather abruptly to the height of 200 or 300 feet. They form the descent of an elevated plain, which extends several miles westward, and is then followed by an escarpment of from 100 to 150 feet elevation, which constitutes the slope of another and more elevated plain. Thus the country extends from east to west in wide plains, which rise one above the other like terraces. About 100 miles from the shores, the plains seem to attain an elevation of near 1000 feet. Their surface is not quite level, but rises a little between the edge of any line of cliffs and the base of the next above it. The plains are traversed by some broad and flat-bottomed depressions. The soil consists of well-rounded shingle mixed with a whitish earth. It is in most places without vegetation. Here and there are scattered tufts of brown wiry grass, and still more rarely some low thorny bushes. In the depressions the bushes are more abundant, and in some places they grow up to stunted trees. Fresh water is seldom found, but salinas, or salt-pools, are numerous. Marine shells are frequently scattered over the plains, but they abound most on the plains nearest to the sea.

The plains are traversed from west to east by the Santa Cruz river, whose mouth is near 50° S. lat. It was ascended by Captain Fitzroy to a distance of 140 miles from the sea in a straight line, and 245 miles by the course of the river. The river runs in a vast excavation below the level of the neighbouring plains. East of 70° W. long., this valley varies between one and five miles in width, and is bounded on both sides by step-like terraces, which near the sea attain an elevation of only 200 feet, but gradually rise higher: west of 70° W. long., they are about 1000 feet above the valley. The valley is hardly more fertile than the plains which surround it, and no bushes grow in the upper part; even the wiry half-withered grass is scanty. West of 70°, the valley contracts in some parts to one mile in width, and here the upper part of the adjacent plains is capped with a layer of lava, which, where it begins, is only 120 feet thick, but farther west increases, so that at a distance of about 40 miles it is 320 feet thick. This part of the plain is 1400 feet above the valley, which is 400 feet above the sea. The lava seems to extend to the foot of the Andes, where the platform of the plains probably attains an elevation of 2000 or 3000 feet. The width of the lava seems to be about 100 miles. The layer of earth on which it rests does not differ from the materials of which the plains near the Atlantic are composed. Within the lava district, between 71° and 72° W. long., the valley is from 5 to 15 miles wide, and there is here a flat tract of apparently good land, exhibiting many swampy places covered with rich herbage; and higher up there is a large plain, on which shrubs, small trees, and bushes are sparingly scattered; yet parts of this plain may be called fertile and woody by comparison with the tracts farther east.

Though Captain Fitzroy ascended the Santa Cruz river within 30 miles from the Andes, and about 60 miles from the Pacific, he found that the volume of water did not diminish, whence he infers that its upper course must be along the base of the Andes from north to south, and that it rises not far from the sources of the southern branch of the Rio Negro, near 45° S. lat. It is supposed to traverse, in this upper course, several lakes, among which is Viedma or Capar Lake, which lies between 48° and 49° S. lat., and is about 30 miles long, and from 10 to 12 wide. On its western side the Andes rise above the snow-line. The Santa Cruz river runs on an average from 6 to 7 knots an hour, and in the course of 200 miles falls 400 feet. At its mouth it forms an estuary, in which the neap-tides rise 18 feet, and the spring-tides from 38 to 42. The extensive shoals which lie near the mouth of this river are ascribed to the meeting of the rapid stream with an extraordinary tide.

The country north of 45° S. lat. differs from the southern plains. The shores are fronted by rocky reefs extending from 2 to 3 miles from high-water mark, which are dry at low tides, and in many places covered with seals. The beach is rather steep, and consists of shingle. Above it extends an undulating country, which at some distance rises into hills. The summits of the hills nearest to the coast are generally of a rounded form, and as it were paved with rounded silicious pebbles, imbedded in the soil, and in no instance lying loose or in heaps. But the hills of the interior are flat-topped and uniform in height for many miles inland. Though the soil here also is gravelly and parched, and in most places exhibits a very scanty vegetation, the valleys and lower elevations are mostly covered with grass and shrubby plants. In several places there are tracts covered with good grass and stunted trees, especially at Camarones Bay and north of it. On the banks of the Chupat river and the western shores of New Bay (Bahia Nueva), there are extensive tracts covered with a fine dark soil, and producing abundance of fire-wood and excellent pasturage. Wild cattle abound, and are very numerous on the natural meadows which extend far inland on both sides of the Chupat river. The river Chupat, at the distance of 20 miles from its mouth, is only 100 yards wide, and six feet deep at low-water, so that only vessels drawing 7 feet water can enter its mouth at high-water. This river runs with a winding course through a wide and fertile valley, over which an immense quantity of drift timber is scattered, and large trees are found several hundred yards from its banks. This circumstance, and the volcanic scoria found on its banks, support the hypothesis that the river rises in the Andes, and inundates its valley to a great extent when the mountain snow is dissolved by the summer heat.

The climate of the plains differs greatly from that of the mountain-region. Their sterility is partly to be ascribed to the nature of the soil, and partly to the want of rain. Westerly winds are prevalent during nine months of the year, and though they drench the western declivity of the Andes with rain, not a drop falls on the plains while they blow. Even during the three winter months (from June to August) little rain falls except on rare occasions, when it comes down heavily for three or four days in succession. Sea-winds sometimes bring small fine rain for a few hours, all through the year, but not enough for the support of vegetable productions. But it appears that rain is more abundant in the interior of the plains north of 45° S. lat. The Rio Negro covers the adjacent country with water to a great extent in autumn (May and June), when no snow on the Andes is dissolved. These inundations are produced by the heavy rains which fall in the interior of the country. Otherwise the climate is healthy and pleasant. Generally a bright sunny day is succeeded by a cloudless and extremely clear night. In summer the heat is scorching, but not sultry; and in winter, though the weather is sometimes very cold, especially during southerly winds, the air is always elastic and wholesome. Changes of wind are sudden, and cause rapid though not very great variations of temperature. Sometimes the sky is slightly or partially overcast, and occasionally clouded heavily, but on most days there is a bright sunshine and a fresh or strong westerly wind.

The plains differ from the mountain-region both in vegetation and in animals. The natives have dogs and herds of horses, and there are wild cattle, as already mentioned, on the banks of the river Chupat. Guanacoes are very numerous, but more so in the southern than in the northern plains. Pumas are found everywhere, and wolves on the northern plains. There are several species of foxes, as well as cavias, armadillos, and tucu-tucu, a little animal like a rabbit. On the coast there are common seals, fur-seals, and sea-lions. Land-birds are not numerous, except emus, condors, and carrion-hawks. Teals, partridges, doves, snipes, and rails however are frequently met with, which pass southward or northward according to the season. The sea-birds consist of gulls, grebes, and penguins. There is no fish in the Santa Cruz river owing to its great rapidity, but on the coast they are rather plentiful, the larger species resembling cod, ling, and salmon. Insects are rare, except scorpions. Between Cape Blanco and Port Desire there are numerous *salinas*, or extensive hollows filled with salt, in which the solid mass is several feet thick, and consists of very white and good salt. Near Port S. Julian there are salt lakes, in which the salt crystallizes in great cubes.

Inhabitants.—The inhabitants of the mountain-region are different from those of the plains. The natives of the plains are called Patagonians, or Horse-Indians, as they wander about in the interior on horseback, and do not live on the shores. The natives of the mountain-region are called Canoe-Indians, because they live only on the sea-coast, and frequently remove from one inlet to another in canoes. The latter are at present comprehended under the name of Fuegians, it being certain that they belong to the same race with the inhabitants of the western part of Tierra del Fuego.

The Patagonians were so called by Magalhaens when he saw them at Port S. Julian in 1520. He found them to be of a gigantic stature, seven French feet in height, and their feet being wrapped up in rough guanaco skins particularly attracted the attention of the Spaniards. Probably their footsteps in the sand were noticed, and excited some such exclamations as 'que patagones!' (what large feet!). His account of the gigantic stature of these people was partly confirmed and partly contradicted by later navigators. About the middle of the last century Captain Byron met with a number of Patagonians, of whom the men were not less than eight feet, and some even exceeded nine in height; the women were from seven feet and a half to eight feet. This account was contradicted by Wallis and Bougainville. It seems that there has been some exaggeration in the accounts of the great stature of the Patagonians; but even the skilful officers who conducted the last survey of these coasts admit that the Patagonians are distinguished by their size. Captain Fitzroy observes that among two or three hundred of these people scarcely half a dozen men are seen whose height is under five feet nine or ten inches, though none have recently been measured who exceeded six feet and some inches. Their head, according to Captain Fitzroy, is rather broad, but not high, and except in a few instances, the forehead is small and low. Their hair, which hangs loosely, is black, coarse, and very dirty. Their brow is prominent, and the eyes rather small, black, and ever restless. Deficiency of eyebrow heightens the peculiar expression of the eyes, and imparts to their physiognomy a mixture of simplicity and shrewdness, daring and timidity, together with that singular wild look which is never seen in civilised man. Their faces are roundish, and the projection of the cheek bones makes them look unusually wide. The nose is a little depressed, narrow between the eyes, but broad and fleshy between the nostrils, which are rather large. The mouth is large and coarsely formed, with thick lips. Their teeth are often very good, though rather large. The chin is usually broad and prominent. All the features are large except the eyes. They have little hair either on the face or the body, and they attempt to eradicate it. Their hands and feet are comparatively small. Their limbs are not so muscular as their height and apparent bulk would induce one to suppose; they are also rounder and smoother than those of white men. Their colour is a rich reddish brown, between that of rusty iron and clean copper, rather darker than copper, yet not so dark as good old mahogany. A large mantle made of skins sewed together, loosely gathered about their bodies and hanging from the shoulders to the ankles, adds so much to their apparent magnitude, that one can hardly be persuaded that they are only a few inches above six feet, till they are actually measured. The Patagonians wander about in the extensive plains south of the Rio Negro, and traverse that immense distance (800 miles) in a comparatively short time. The same individual was seen at Gregory Bay in the Strait of Magalhaens, in November, 1831; at the Rio Negro, in September, 1832; and again at Gregory Bay, in March, 1833. Their principal subsistence is the flesh of mares, emus, cavias, and guanacoes. They broil their meat and eat it with a lump of fat and salt. There are two wild roots which they eat, one called *tus*, and the other *chālās*. The *tus* is a bulbous root, which, when cleaned and baked, becomes nearly like a yam. The *chālās* is a long white root about the size of a goose-quill, and is eaten roasted or put in broth which they make for women and sick people. Dogs are not eaten, nor are horses, unless disabled by accident. Their huts are in shape not unlike gipsy-tents. They consist of poles stuck in the ground, to which others are fastened; the whole is covered with skins sewn together, except towards the east, where they are open.

That tribe of Patagonians which principally visit the southern plains is called Te-huel-het, or Southern People. In the stony district between 49° and 45° none of the tribes seem to make a long stay. North of 45° there are said to be three other tribes: the Pe-huel-che, or Eastern People, who move about in the country along the coast; the Chilian Indians, who ramble over the districts adjacent to the Andes south of 42°; and the Molu-che, or Warrior Indians, who occupy the interior of the country south of the Rio Negro to about 42° S. lat.

The mountain-region is inhabited by two tribes of the Fuegians. Near Otway and Skyring Waters is a tribe which Captain Fitzroy calls Huemul, because they have many skins of a kind of roebuck, which is called by Molina, in his 'History of Chili,' huemul. Another tribe, which inhabits the western coast of Patagonia, between the Strait of Magalhaens and the promontory of Tres Montes, he calls Chonos, founding the name on the supposition that this tribe once advanced as far north as Chiloe, and spread over the Chonos Archipelago, which at present is quite uninhabited. The Fuegians are rather short, varying in height from 4 feet 10 inches to 5 feet 6 inches, yet their bodies are as bulky as those of a man of six feet. Their limbs and joints are short in proportion to the trunk, which gives them a clumsy appearance. Passing so much time in their huts (wigwams), or cramped in small canoes, the shape and size of their legs are injured, and they move about in a stooping posture, with the knees much bent. Their colour is that of old mahogany, or rather between dark copper and bronze. The average height of the women is four feet and some inches. The most remarkable traits in their countenance are, an extremely small low forehead, a prominent brow, small eyes, wide cheek-bones, wide and open nostrils, a large mouth, and thick lips. Their eyes are black, sunken, and as restless as those of savages in general. The nose is always narrow between the eyes, and almost flat. The hair is black, coarse, and lank. Their shoulders are square but high, and the chest and body very large. The arms and legs are rounder and less muscular than those of Europeans. The muscles of the thighs are large, but those of the legs small. It is remarkable that, though living in a very cold climate, they have seldom any covering, for a scrap of hide, which is tied to the side or back of the body by a string round the waist, serves only as a pocket. The women have generally a seal skin wrapped about them and a diminutive apron. Their canoes are made of sevepieces of bark sewed together, from 12 to 20 feet long, and from 1 to 2 feet wide in the middle, the extremities being drawn together. Their wigwams or huts are shaped like bee-hives, about 6 feet high and from 4 to 8 yards in diameter. They are made of branches of trees, stuck into the ground and bent together towards the top, on the outside of which skins, pieces of bark, and bunches of coarse grass are roughly fastened. The Chonos Indians have canoes, or rather boats, made of planks sewn together with strips of twisted bark and caulked. These boats are nearly 30 feet long and 7 feet broad, and are pulled with oars. The tribes are dispersed among the islands in small families, on account of the scarcity of food. They live only on seals, birds, fish, and particularly shell-fish, and they are consequently always moving from one place to another. During the summer they prefer the coast, where they obtain a great quantity of eggs and young birds, besides seals, which come to shore to breed at that season. In winter they retire more to the interior parts in search of shell-fish, and the small but numerous and excellent fish which they catch among the sea-weed (*Fucus giganteus*). The Fuegians, like all savages living on the produce of fishing, seem much more inclined to improve their condition by adopting the habits of foreigners than the Patagonians or other American tribes who subsist by the chase.

PATAN. [Hindustan, vol. xii., p. 225.]

PATAPSCO. [Maryland.]

PATIAN. [Sulo-Archipelago.]

PATEL. This painter was a native of France, but neither his age nor the master under whom he studied is known, which is not a little surprising, considering the high and deserved admiration in which his works are held. He appears to have taken Claude Lorraine for his model, and in his own country he is called the French Claude. It cannot indeed be said that he equalled that great artist, yet it is no mean honour to have imitated him successfully. His works show that he diligently studied nature. His subjects were always well chosen; his foregrounds are judiciously broken, his distances admirable; the scenery, rocks, and the forms of his trees remarkably elegant and airy. The antique buildings, ruins of aqueducts, vases, and other ornaments give great variety and richness to his pictures. His touch is light and firm, and his colouring clear and natural. His figures are superior to those of Claude, being generally elegant and correctly drawn.

PATELLA. [Skeleton.]

PATELLA. [Cervicobranchiata.]

PATENT. Before applying for a patent for an invention, two considerations are necessary: first, what is entitled to a patent; and next, whether the invention has the requisite conditions.

In the first place, the machine, operation, or substance produced, for which a patent is solicited, must be new in public use, either the original invention of the patentee, or imported by him and first made public here. A patent may be obtained for England, Ireland, or Scotland, although the subject of it may have been publicly known and in use in either or in both of the other two countries.

In the second place, the subject of the invention must be useful to the public, something applicable to the production of a vendible article, this being the construction put upon the words 'new manufacture' in the statute of James I. The discovery of a philosophical principle is not considered entitled to such protection; such principle must be applied, and the manner of such application is a fit subject for a patent.

Inventions entitled to patent may be briefly enumerated as follows:—

1. 'A new combination of mechanical parts, whereby a new machine is produced, although each of the parts separately be old and well known.

2. 'An improvement on any machine whereby such machine is rendered capable of performing better or more beneficially.

3. 'When the vendible substance is the thing produced, either by chemical or other processes, such as medicines or colours.

4. 'Where an old substance is improved by some new method, the means of producing the improvement is to be considered a new principle.'

If the inventor finds that the machine, operation, or substance produced comes under any of these enumerations, and that it is new, and likely to be useful to the public, he may enter a caveat at the Patent Office, and at the offices of the attorney-general and the solicitor-general, in the following form:—

'*Caveat* against granting letters-patent to any person or persons for (here describe the invention in the most general terms), without giving notice to A. B., of , in the county of .'

(Date.)

These caveats stand good for twelve months, and may be renewed from year to year: the fee for entering such caveat is 5*s.* at each office.

As soon as the caveat is entered, the inventor may find it necessary to obtain the assistance of workmen or others, in order to carry his invention into effect; and if in doing this he should make known to them his invention, he will not thereby lose his right to a patent. Any communication which is necessary for carrying his ideas into effect is not considered as a legal publication, which would of course vitiate his right, as the invention could no longer be called new. But though the inventor is thus protected in his experiments, and is safe while dealing with honest people, he is not protected against fraud. If a person in the secret should make such invention public, or cause it to be used by several persons between the time of entering the caveat and the next stage of proceeding, that of sending in the petition, no patent could be obtained, as the declaration that accompanies the petition could not be made, or, if made, would be untrue. Again, if such workman, instead of making it public, were to give to some other person the necessary information, the latter might apply for a patent for such invention as his own; and if he could succeed in concealing the source of his information by a false declaration, he might force the real inventor to allow him to participate in such patent, or to forego it altogether. The caveat can do no more than prevent any one stealing the ideas of an inventor and appropriating them to his own use, to the exclusion of the inventor; and it will also ensure notice of any application for a patent for a similar invention, and, in some cases, prevent the expenditure of time and money upon a subject for which no patent could be obtained. This is all that a caveat can do: its effect is frequently much overrated. If any one apply for a patent, the title of which is similar to that contained in the caveat, the attorney or solicitor general will send a notice of such application to the enterer of the caveat, who, if he should think such application likely to interfere with his invention, must, within seven days from the receipt of the notice, state in answer his intention of opposing such patent.

The attorney or solicitor general then summons the applicants to appear separately before him; and if he should be of opinion that the two patents will interfere with each other, or are virtually the same, the usual course is not to grant any patent except to the two claimants conjointly, though if priority of invention can be proved by either, he has undoubtedly the right to the protection of the statute.

If the invention is of such a nature that it can at once be perfected or put into operation, no caveat is needed; and indeed a caveat may be the means of exciting the very attention and opposition which it is intended to prevent. Where some experiments or operations which require assistance must be performed before a definite title can be given to the invention, as must be done in the declaration and petition, it is much better to avoid the caveat, and by getting the different parts of the machinery or operations performed by different persons, if possible, keep the invention a secret until the patent right be secured.

The next step is to draw up a petition to the crown, before doing which however the title of the patent must be settled. To those who have not considered the subject, this may not seem a very difficult matter, but in fact it requires the greatest care; for the least discrepancy between the title and the description contained in the specification will endanger the patent. (See the evidence of Mr. Farey and others before a Committee of the House of Commons upon this subject, 1829.)

The title should set forth the subject of the patent in such terms that any one may see if a patent has been taken out or applied for in the case of any similar invention.

The titles of patents collectively should form an index of the inventions thus protected. It is a common practice however to make the title as obscure as it can be made without endangering the patent, in order that the real object of it may be kept secret. But this is a matter of great difficulty, and has often justly vitiated a patent. The law requires all patented inventions to be open to public inspection, and the enterer of a caveat may be cheated by a title, for although the subjects may be the same, a title may express the invention so faintly, or indeed so falsely, that the similarity of two inventions may escape the notice of the attorney-general, and injustice may be done by granting a patent to one party while priority of invention belongs to another. By the 5 & 6 Will. IV., c. 83, a patentee is allowed to enter a disclaimer of any part of the title or specification with the consent of the attorney-general or solicitor-general, who may order such disclaimant to publish his disclaimer. This act supplies a remedy for unintentional errors, but is ineffectual where the title is purposely made obscure. Besides this, the disclaimer does not operate retrospectively, so that if an action be commenced before the entry of the disclaimer, the title and specification must be adduced on the trial as they originally stood. A caveat may be entered against the granting of such disclaimer.

The following are a few instances of patents being lost through defective titles:—

In the case of King *v.* Metcalfe (2 Starkie, N. P. C., 249), the subject of the patent was a hair-brush, in which the hairs were of unequal length: in the title it was described as a 'Tapering Brush,' which was considered as intended to mislead the public, as not being a description of the subject of the patent, and it was annulled accordingly. In Cochrane *v.* Smethurst (K. B., 1 Starkie, 205), the patent was for a certain lamp, but the title called it an 'Improved Method of lighting Cities, Towns, and Villages.' The patent in this case was held to be void, as the specification only described a new lamp, and not an 'improved method of lighting' at all; and it was also objected, that as it was equally applicable to lighthouses, harbours, shipping, &c., the title was otherwise imperfect. If the title had been for an 'Improved Lamp' or an 'Improvement on Lamps,' the patent would have been valid. In the case of King *v.* Wheeler, the patent set forth in its title a 'New and Improved Mode of Drying and Preparing Malt,' whereas the specification described a method of reburning malt which had already been made, so as to produce a colouring matter for beer and other liquors. Now it is evident that if any one had intended to take out a patent for producing colouring matter, he would never have collected from this title that the patent was likely to interfere with his invention. In the case of Bloxam *v.* Elsee (6 Barn. and Cress., 169 & 178), the title of a patent which came in question was 'A Machine for making Paper in Single Sheets, without Seam or Joining, from 1 to 12 feet and upwards in width, and from 1 to 45 feet and upwards in length.' The specification however described a machine only capable of producing paper of one width or to a certain width. Now if an inventor who thought of taking a patent for a machine to make paper of a greater width than 12 feet had looked at the title only of this patent, he would have supposed that such a patent already existed; but if he had inspected the specification, he would have found that it did not bear out the title, as the machine therein described was not capable of making paper of a width greater than 12 feet. The patent then was invalid, as the title comprised more than the specification. This is the most common error that patentees fall into. Jessop's case, cited during the trial of Boulton and Watt against Bull, in 1795, by Mr. Justice Buller, is another instance. A patent was taken out for a 'New Watch,' whereas the specification only described a particular movement in a watch, which was the real invention, and the patent was therefore void.

An honest and valid title may be stated, in a few words, to be, a description of the precise object of the invention in the most simple language.

The title being settled, the petition must be drawn in the following form:—

'The humble petition of A. B., of , in the county of .

'Showeth,

'That your petitioner hath invented (here insert the title which you intend the patent to bear), that he is the first and true inventor thereof, and that it has not been practised by any other person or persons whomsoever, to his knowledge and belief.

'Your petitioner therefore most humbly prays that your Majesty will be graciously pleased to grant unto him, his executors, administrators, and assigns, your royal letters-patent under the great seal of Great Britain for the sole use, benefit, and advantage of his said invention within England and Wales and the town of Berwick-upon-Tweed, *and also in all your Majesty's colonies and plantations abroad*, for the term of 14 years, pursuant to the statute in that case made and provided.'

The passage in Italics must be omitted if the inventor does not intend to obtain patent for the colonies. This petition, with a declaration annexed, must be left at the office of her Majesty's secretary of state for the home department. The declaration is in lieu of the affidavit which was required until the passing of the Act 5 & 6 Wm. IV., c. 62.

A few days after the delivery of the petition, the answer may be received; which contains a reference to the attorney or solicitor general to report if the invention is deserving of letters-patent. If such report be favourable, it must be taken and left at the Home-office for the queen's warrant, which is addressed to the attorney or solicitor-general, and directs the bill to be prepared. The bill is in effect the draft of the patent, and contains the grant with an allusion to the clauses and provisos in the letters-patent. It is signed by the secretary of state for the home department, and by the attorney or solicitor general. If at this stage of the proceeding any person should wish to oppose the patent, a caveat may be entered in the manner already described, but the enterer is required to deposit 30*l.* at the office of the attorney or solicitor general to cover the patentee's expenses if he should succeed in establishing his right to patent. The bill, when prepared, must be left at the office of the secretary of state for the home department for the queen's sign manual. It must then be passed at the signet-office, where letters of warrant to the lord-keeper of the privy seal will be made out by one of the clerks of the signet; and lastly, the clerk of the privy seal will make out other letters of warrant to the lord chancellor, in whose office the patent will be prepared, sealed with the great seal, and delivered to the patentee. Considering the number of offices through which a patent passes, it might be supposed that the inquiry into the validity of the claim is very rigid, and that, when once the patent is sealed, it is safe from opposition. But in reality the law officers through whose offices it is carried exercise no opinion upon the validity of the patentee's claim; the whole responsibility rests upon himself, as will be seen by perusing the following abstract of the form of letters-patent:—

The first part of the patent recites the petition and declaration, and sets forth the title which has been given to the invention by the inventor.

The 2nd relates to the granting the sole use of the invention to the inventor for the space of fourteen years, whereby all other persons are restrained from using the invention without a licence in writing first had and obtained from the patentee, and persons are restricted from counterfeiting or imitating the invention, or making any addition thereunto or subtraction therefrom, with intent to make themselves appear the inventors thereof. This clause also directs all justices of the peace and other officers not to interfere with the inventor in the performance of his invention.

The 3rd part declares that the patent shall be void, if contrary to law or prejudicial and inconvenient to the public in general, or not the invention of the patentee, or not first introduced by him into this country.

The 4th declares that letters-patent shall not give privilege to the patentee to use an invention for which patent has been obtained by another.

The 5th relates to the manner in which letters-patent become void, if divided into more than a certain number of shares. The number of such shares used to be five, but all patents sealed since May, 1832, allow the interest to be divided between twelve persons or their representatives. This part also relates to the granting of licences.

The 6th contains a proviso that a full and accurate description or specification shall be enrolled by the patentee in a specified time.

The 7th directs the patent to be construed in the most favourable manner for the inventor, and provides against inadvertency on the part of the clerk of the crown in enrolling the privy-seal bill.

Letters-patent then only grant the sole use of an invention for a certain time, provided that the statement in the declaration be true, that the title give a distinct idea of the invention, and that the specification be enrolled within a certain time mentioned in the patent, generally two months for England, four for England and Scotland, and six for the three countries together. This time depends on the attorney or solicitor general; a longer or shorter period being granted according to the extent or difficulty of the invention; in some instances two years have been allowed for specifying.

The object of the specification is twofold:—

First, it must show exactly in what the invention consists for which a patent has been granted, and it must give a detailed account of the manner of effecting the object set forth in the title. It must describe exactly what is new and what is old, and must claim exclusive right to the former: the introduction of any part that is old, or the omission of any part that is new, equally vitiates the patent.

In the second place, a patent is granted for a certain number of years on the condition that such full and accurate information shall be given in the specification as will enable any workman or other qualified person to make or produce the object of the patent at the expiration of that term without any further instructions. A specification is bad, if it does not describe the means of doing all that the title sets forth: it is equally bad if it describes the means of effecting some object not stated in the title: it is incomplete if it mentions the use of one substance or process only, and it can be proved that the inventor made use of another, or that another known substance or process will answer the purpose as well; and it is false if more than one substance or process are described as producing a certain effect, and it be found that any one of these is incompetent for the purpose. Patentees frequently render their patents invalid by claiming too much; thus, after describing one substance or process which will answer a certain purpose, they often conclude by some such expression as, 'or any other fit and proper means.' The following is an instance in which a patent was set aside by such an expression. In specifying a machine for drying paper by passing it against heated rollers by means of an endless fabric, the inventor, after describing one sort of fabric, the only one in fact which he used, went on to say that any other fit and proper material might be used. Now if he used any other means of effecting the object, such means should have been distinctly described. This alone rendered his specification incomplete; but, besides this, it was proved that no other fabric would answer the purpose, or rather that no other was known, and the patent was annulled accordingly. The cases which have been already mentioned as instances of bad titles will, by supposing the title to be good, be converted into instances of bad specifications, as the invalidity arises from the title and specification not agreeing with each other. It is not necessary to say anything further on the necessity of the greatest care in drawing up the specification.

The patentee may describe his invention just as he pleases, and he may illustrate such description by drawings or not; but he should be careful to use words in their most common acceptation, or if some technical use should have perverted their meaning, he should make it appear distinctly that he intends them to be taken in such perverted sense. Subjoined is the form of the other part of the specification.

'To all to whom these presents shall come greeting, I the said (patentee's name and residence) send greeting. Whereas her most excellent Majesty Queen Victoria, by her letters patent under the great seal of Great Britain, bearing date at Westminster, the day of , in the year of her reign, did give and grant unto me the said A. B., my executors, administrators, and assigns, her special licence, full power, sole privilege and authority, that I the said A. B., my executors, administrators, and assigns, and such others as I the said A. B., my executors, administrators, and assigns, should at any time agree with, and no others, from time to time, and at all times hereafter during the term of years therein mentioned, should and lawfully might make, use, exercise, and vend within England, Wales, and the town of Berwick upon Tweed, and also in all her said Majesty's colonies and plantations abroad (if such be the case), my invention of (here insert the title set forth in the letters patent verbatim); in which letters patent there is contained a proviso that I the said A. B. shall cause a particular description of the nature of my said invention, and in what manner the same is to be performed, by an instrument in writing under my hand and seal, to be enrolled in her said Majesty's High Court of Chancery within calendar months next, immediately after the date of the said in part recited letters patent, reference being thereunto had may more fully and at large appear. Now know ye, that in compliance with the said proviso, I the said A. B. do hereby declare the nature of my invention and the manner in which the same is to be performed are particularly described and ascertained in and by the following description thereof, reference being had to the drawings hereunto annexed, and the figures and letters marked thereon, that is to say, my invention consists (here insert the description of the invention). In witness whereof I the said A. B. have hereunto set my hand and seal this day of , 1840."

(Name and seal.)

'Taken and acknowledged
by A. B., party hereto,
the day of 1840,
at .

'Before me,

'B—— C——

'A master (or master extraordinary)
in Chancery.'

The specification being completed, it only remains to enrol it before 12 o'clock on the day of the expiration of the time allowed in the letters patent. All specifications are open to public inspection upon payment of a small fee, and books are kept at the Patent-office, Lincoln's Inn, which contain a list of all patents in force. These books may be inspected, by permission of the clerk, without any charge whatever.

Extension of Term of Letters Patent.—If a patentee finds that the time allowed him by the patent is not sufficient to remunerate him for the trouble and expense of his invention and patent, he may apply for an extension of the term. This used to require a petition to parliament, but by the before-mentioned Act of William IV., the patentee, after advertising his intention to apply for an extension of his patent in the manner required by the Act, may petition the king in council to that effect. Any person wishing to oppose the extension must enter a caveat at the Privy Council-office, and the petitioner and enterer of the caveat or caveats are heard by their counsel before the Judicial Committee, which reports to the king; and the king is authorised, if he shall think fit, to grant new letters-patent for the same invention for a term not exceeding seven years after the expiration of the first term. There were four or more such grants in the year 1837. The application must be made so as to allow time for the grant before the conclusion of the original term, according to 5 & 6 Wm. IV., c. 83; but this condition is somewhat modified by 2 & 3 Vic., c. 67.

Scotch and Irish patents are obtained by process similar to that described for England; the applications however are made to the respective law officers of each country.

The complicated nature of the proceedings in obtaining a patent has led to the establishment of a class of persons who make it their business to obtain patents for inventors; and in case of an intricate invention, it is far better for an inventor to employ one of these 'patent agents' than to run the risk of the errors and loss of time which may be occasioned by his inexperience. The fee charged by the clerks of the Patent-office, who act also as agents, is ten guineas, exclusive of the drawings and descriptions, which of course vary according to the difficulties of the subject; a small sum comparatively, when the loss of time and risk of a faulty title or specification are taken into consideration.

The time necessary for obtaining a patent is seldom less than two months, and frequently much longer. This is justly considered a great grievance, as the inventor is not secure until the great seal is attached, and no reason can be assigned for this delay, except that the patent passes unnecessarily through a great number of offices. The expense also is very heavy, and may be stated on an average at 120*l.* for England, with 5*l.* additional for the colonies, 100*l.* for Scotland, and 125*l.* for Ireland.

It is evident that there are many inventions which will not bear this outlay of capital, and the consequence is that the number of patents is much smaller than it would be under a more moderate arrangement. This may seem at first sight to be beneficial to the public, but such is not the case. The inventor, if he procure a patent, will take care that although he may be the party inconvenienced at first by the outlay, the public shall pay for it eventually; and, if he do not take out a patent, he will do all in his power to keep his invention secret for a longer time than the patent would have allowed. This circumstance has given rise to much of that jealousy which is so apparent among manufacturers; it has materially retarded the study of the arts, which are now fenced round with secrets and difficulties, and has been mainly instrumental in causing the great want which confessedly exists, of men conversant at once with the theory and the practice of mechanical operations.

The truth of these observations will be admitted by all who have been in any way connected with manufactures; but if any evidence be wanting to convince those who are not, the small number of patents taken out in England is quite conclusive. In 1837 the number of English patents was 254, and that of Scotch 132; the numbers in France and Prussia were much larger. Much has been said against the present law of patent, which in our opinion is unfounded in truth. There are difficulties connected with the title and specification which cannot perhaps be smoothed by any legislative enactments; but the obstacles which the law has placed in the way of inventors can be easily removed. There is nothing to prevent patents being granted in a quarter of the present time, and at a tenth part of the present expense. When this is done, the number of patents will rapidly increase; talent, which is inert for want of motive, will be called into action, and the workshop will no longer be closed against the philosophic inquirer.

PATENT. [Patterns.]

PATENTS. (Law.) The law relating to patents for inventions is founded on the 21 James I., c. 3, to which reference is made in the article Monopolies, and on the cases decided under that statute. It is also somewhat modified by the 5 & 6 Wm. IV., c. 83, and 2 & 3 Vic., c. 67.

The grant of a patent is not a thing which the subject can claim as a matter of right; it is the free gift of the crown. The form of the grant is by letters-patent, which, being the deed of the crown, are considered as of public record. The property acquired by the grant of a patent consists in the sole right of making a certain material thing, or of putting together material things in certain specified proportions or forms, in order to produce some definite result; and it also consists in the sole right of selling or allowing to others the use of such material thing or the means of producing such definite result. The grant of a patent endures for fourteen years from the date of the first letters-patent, or for such other time under fourteen years as the grant may contain. A patent cannot be held in any way so that more than twelve persons shall be interested in it. With the exceptions above mentioned, a patent is in all other respects like personal property, and of course may be sold or disposed of by will. The patentee may also grant licences to other persons to use his patent.

If the patent is infringed, the patentee or his assignee may bring his action for damages against the offender. The patentee or his assignee may also file a bill in equity against the infringers of the patent, and this is generally the best method of proceeding. On a bill being filed, immediately on the discovery of the infringement, which states a proper case and is supported by affidavits, an injunction may be obtained restraining the defendant from violating the patent until he puts in his answer or until further order of the court. The defendant may move to dissolve such injunction upon filing his affidavits, or he may make such motion on putting in his answer. When an injunction cannot be obtained either before the answer or upon the answer, and there is a doubt about the validity of the patent right or the infringement of it, the court will generally direct the defendant to keep an account of the proceeds of his manufacture, and will also either direct an issue to try the facts of validity or infringement, or leave the patentee to bring his action. If the patentee can establish the validity of his patent in a court of law, the court of equity will then grant an injunction against its infringement.

There is a further advantage in applying to a court of equity in the case of an infringement of a patent; the court can direct the trial at law in such manner as it thinks just, and can order parties to be examined on the trial who would not otherwise be competent witnesses; and when the alleged fact of infringement is done secretly, it can order the manufactory or workshop to be inspected.

Letters-patent may be invalid on various grounds, although the invention is actually a new one. These grounds, as appears from the statute of James (s. 6), may be, that they are 'contrary to the law,' or 'mischievous to the state by raising the prices of commodities at home,' or 'hurt of trade or generally inconvenient.' The proceeding by which a patent is cancelled is a writ of scire facias. The nature of the former of these two objections is shown in the article Monopolies, but it is a ground for cancelling a patent which can now hardly occur. The other ground, that of a patent being mischievous to the state, is also not likely to be of common occurrence; but if an issue were joined on facts which showed that a patent was mischievous to the state, such issue might be tried, and the patent might on that ground be declared void. The patent is of course also void, and may be cancelled if it is proved that the patentee is not the true and first inventor, that the object is not some 'new manufacture,' in the sense which judicial decisions have given to those words in the statute of James, or that the specification is not correct enough, or that the patent has not been properly obtained.

PATENT, LETTERS. [Letters Patent.]

PATENT YELLOW, a pigment composed of oxide and chloride of lead, or oxichloride of lead, for the preparation of which several processes have been proposed, as by decomposing common salt with litharge, or oxide of lead, and heating the residue, after separating the soda by washing. It is sometimes formed by heating together one part of chloride with 4 or 5 parts of oxide of lead, or by heating 10 parts of oxide of lead with one part of hydrochlorate of ammonia (sal ammoniac). It is of course constituted of different proportions of the compounds which form it, according to the method in which it is prepared. Since the introduction of chromate of lead, it is much less used than it was formerly.

PA'TERA, an open vessel approaching to the form of a cup, used by the Romans in their sacrifices, in which they received the blood of the victims, and with which they made libations. The word contains the same root as *pateo*: 'Patera ut et ipsum nomen indicio est, poculum planum ac patens est' (Macrobius, *Saturn*, v. 21). Virgil, in several passages of the 'Æneid,' alludes to the uses of the patera as—

Lib. vi. 248. Supponunt alii cultros, tepidumque cruorem
Suscipiunt pateris.
Lib. iv. 60. Ipsa tenens patera dextram pulcherrima Dido,
Candentis vaccæ media inter cornua fundit.
Lib. vii. 133. Nunc pateras libate Jovi.

On medals the patera is represented in the hands of several of the deities (Rasche, *Lexicon Universalis Rei Numariæ*, tom. iii., part ii., pp. 626, 627), and frequently in the hands of princes, to mark the sacerdotal authority as joined with regal power. The patera was of gold, silver, bronze, marble, glass, or earth. Such as had served for libations of wine or any other liquor at a funeral were usually deposited with the ashes of the deceased. Patella (that is, paterula) is the diminutive of Patera.

PATE'RCULUS, VELLE'IUS, was born about 19 B.C. He served in the army under Augustus, was made military tribune, and accompanied Tiberius in his German and Illyrian campaigns. On his return to Rome he was appointed successively quæstor, tribune of the people, and lastly prætor, which office he filled in the year of the death of Augustus. He wrote his abridgment of Roman history, which he addresses to the consul Vinicius or Vinucius Quartinus, A.D. 30, the year before the proscription of Sejanus. Paterculus is supposed to have lost his life at the time when Sejanus suffered, as he was a friend of that favourite, whom he praises in a rather fulsome strain towards the end of his work. The 'Historiæ Romanæ' of Paterculus consist of two books. The first begins with a brief notice of the early history of Greece after the Trojan war, and of the Greek colonies in Italy; it then mentions the foundation of Rome and the establishment of a senate by Romulus, after which there is an hiatus of 600 years, occasioned by the loss of that part of the MS. The work, as we have it, is resumed at the time of the war against Perseus, and briefly relates its result, as well as the destruction of both Corinth and Carthage. The second book is complete, and written more at length. It treats of the disturbances of the times of the Gracchi, of the civil wars of Marius and Sulla, of the wars between Cæsar and Pompey, of the second triumvirate, and lastly of the reign of Augustus, concluding with a panegyric on Tiberius and Sejanus. It serves in some measure as a substitute for the lost books of Livy. The writer expresses himself with tolerable fairness concerning the civil wars, until he comes to his own times, when he adopts a laudatory style towards the existing powers. His diction is elegant and fluent. The work of Paterculus has been often printed. The Bipont edition, 1780, with Dodwell's 'Annales Velleiani,' is a useful edition.

PATERNO. [CATANIA.]

PATHOLOGY (from πάθος, 'disease,' and λόγος, 'a discourse') is the science of diseases, and especially of those which affect men and animals which are the subjects of medical treatment.

For the perfect knowledge of the nature of a disease, the first circumstance to be determined is its cause; and this is commonly regarded as twofold. The predisposing cause or condition (for the term cause cannot fairly be used in this sense) is that state of any individual which renders him peculiarly liable to the attack of any or of some particular disease, of which another person or he himself at another time might be in little danger. Of these predisposing conditions the most important is hereditary disposition, by which an individual being constructed with the same peculiarities of internal and of external form and composition, which one or both of his parents possessed, is liable to the same diseases as they were. Such are the peculiarities of temperament or constitution with which each individual is born, and by which he is through life disposed to a peculiar character of disease; and such also are the special hereditary dispositions to scrofula, gout, insanity, some forms of asthma, and probably many more diseases. Other predisposing conditions are the peculiarities of constitution which are acquired in the course of life by particular modes of living. Each individual is adapted by habit and other circumstances to the conditions of climate, &c. in which he is placed, and is peculiarly liable to be affected by changes of these external conditions. A person of effeminate habits living carefully secluded from all excitants of diseases, is much more liable to be affected by exposure to any of them, than one whose frame by a hardy course of life is rendered comparatively invulnerable to all. Any means by which the strength of the body is reduced render it more liable to diseases of all kinds, and hence our idea of bodily strength is drawn not more from the muscular power of the individual than from his immunity from the effects of those circumstances which in others excite disease. There are also local peculiarities of individual organs of the body which render them especially liable to disease; such are the state bordering upon disease which is brought on by constant over-excitement of any organ; the condition of an organ which has once been affected with a disease, and which is commonly thenceforward particularly liable to a repetition of it; the state of the organs which at different periods of life renders one more than another liable to disease, so that the same excitant will be most likely to produce in the child an affection of the head, in the youth a disease of the chest, and in the adult or old person some disorder of the abdominal organs.

Any of these predispositions however may exist throughout life without the occurrence of actual disease; in order to produce disease, some more immediate or exciting cause is necessary. This excitant must be the more powerful the less the predisposition; but under whatever circumstances disease is produced, the predisposing condition of the patient may be expected to confer upon it a corresponding peculiarity of character. The exciting causes of disease are any changes of a certain extent in the conditions of the external circumstances in which man is placed. For example, a certain range of external temperature, a certain constitution of the atmosphere, a certain supply of pure food and drink, a certain amount of mental and bodily exertion, are circumstances essential to health, and alterations in any of them may produce disease, of which the nature and the seat will be determined in part by the predisposition of each individual, and in part by the peculiar mode of action of the excitant. Thus after the same exciting cause (for example, exposure to cold and damp), one person may have rheumatism, another pleurisy, a third ophthalmia, and a fourth may escape altogether unharmed. But there are other excitants of disease which prevail over all predisposition, and produce a certain character of disease, which the constitution of the patient can only slightly modify; such are the materials of all contagious and epidemic disorders, as influenza, small-pox, measles, &c., which produce in all whom they attack a similar affection. Many persons however escape from the effects of these excitants, and by long exposure become inured to them; hence the diseases of peculiar climates (endemics) affect foreigners much more than natives; but even in those persons in whom they do not produce disease, these excitants, which are excitants of disease in others, modify the characters of diseases that occur from any other source; and hence in the course of an epidemic all diseases have a tendency to assume some of the characters of that which is prevalent. Other excitants of disease, still more universal in their influence and more constant in their consequences, are all things which act immediately on the composition or construction of the body or of the blood, such as mechanical and chemical injuries, including poisons of all kinds.

The nature of a disease being determined by the condition of the individual and the exciting cause to which he is exposed, the next division of pathology is the study of the symptoms or signs by which the progress of a disease is marked, and by which in practice its nature is to be determined. Of these signs of disease, many are expressive of the altered condition of the part chiefly affected, as pain in a wound, or a local inflammation, coughing in a disease of the lungs, sickness in a disorder of the stomach; but a greater number are the expressions of an affection of other organs, which suffer in association with those primarily diseased; such are pain in the head when the digestion is disordered, coughing in diseases of the liver, sickness after violent blows on the head. Sometimes these secondary symptoms completely mask those immediately resulting from the primary disease; as when in a disease of the hip the chief pain is felt in the knee, or in hysteria any organ may appear disordered except that which actually is. These secondary symptoms are ascribed to what is called sympathy, an unsatisfactory expression indicating only the coincidence and probable connection of symptoms of disease in two organs, of which one only is supposed to be materially affected. Entire ignorance must be confessed of the nature and origin of many of these sympathetic or indirect symptoms of disease; as, for example, of the fever consequent on local injuries or acute local diseases, and of the hectic fever of many chronic affections; but it is probable that all symptoms will in time be found to depend either on some communication of excitement from one nerve to another through the medium of the spinal chord or brain, as in the reflex actions [NERVE], or on some change in the blood which affects both organs at once, or which, originating in the disease of one disturbs the functions of the other or of the whole body.

Whether directly or indirectly produced, all the symptoms of disease are only the perversions of the natural functions of the part affected, or appreciable changes in its structure; their value and meaning therefore can only be determined by a comparison with the same functions and structure in health: in other words, this, like all other parts of pathology, cannot be rightly studied without a constant reference to physiology. It is believed that an organ may be only functionally deranged; that is, that its several functions may be performed in a very unhealthy manner, without the existence of any material change in its structure and composition. These are called functional symptoms, but their number is probably much less than is generally believed, and it is most likely that they are limited to the variations to which the organs are subject by the changes in the mode and measure of the influence of the nerves upon them. For all other symptoms we must assume the existence of a substantial change in the part affected, or in the materials on which it has to act, although in many cases these changes are fugacious or inappreciable by our senses.

For a due performance of all the functions of organic life [LIFE], a healthy structure of each organ, and a healthy composition of the blood, on which they all act and all depend for their own maintenance, are alike necessary; a deviation from health in either will therefore produce the symptoms of disease; a conclusion in which the long continued disputes of the humoral pathologists, who ascribed all disease to the blood, and the solidists, who held all to depend on changes of structure, have at length merged. To these two kinds of alterations, and to perturbations in the distribution of the nervous influence, it is probable that the signs of all diseases may be referred; but from the peculiar and complicated nature of the animal body, and the universal connection between all its organs, no one of these changes can long continue without producing the others; and hence in diseases of any degree of severity the symptoms are commonly a mixture of the disorders of all the functions of the body, and the disorder of each is modified by the changes in all those circumstances on which its healthy state depended, as the condition of the blood, of the nervous influence, &c. Neither are the symptoms in any case constant phenomena; for the influences of all external circumstances upon a diseased body are very different from those which they exert upon the healthy body, and many things which were necessary to health are supporters of disease, as the usual amount of food, of bodily and mental exertion, &c.; so that exclusion from them becomes necessary, and this again further modifies the performance of the disordered functions.

The history of a disease is completed by the process of natural recovery or by the observation of the changes in the structure of the body which it produces. The influence of remedies cannot justly be considered as a branch of pathology; though most important for their utility, still, in their relations to the natural history of a disease, medicines can only be regarded as interfering circumstances, or as the means of experiments for the determination of the relation of the diseased body to particular agents, by which the nature of the disorder affecting it may be sometimes ascertained.

The recovery from disease is an example of the exercise of that power by which the body can make unusual efforts to prevent its own destruction: this has been called the vis medicatrix naturæ, or curative force of nature. It is exerted in many cases in which disease cannot be said to exist, but where rather there is an exaggeration of health; as, for example, when a muscle subjected to unusual exertion and an unusually great amount of waste not only repairs its loss, but actually becomes larger and stronger, so that it can bear the same amount of constant waste better than at first; or as when a person is exposed for a time to cold in bathing, the speedy consequence is an increased warmth of the surface. The term reaction is applied to phenomena of this kind, and it may be said that reaction takes place whenever any injurious influence is applied to the body. In simple cases the reaction effects at once a restoration to health, as in the instances above mentioned; in others the reaction is itself the most prominent feature of the disease, as in fever and inflammation.

The recovery from disease is rarely perfect. Although no visible change may be left behind, yet the part diseased is commonly for ever after weak, that is, more than usually liable to the same or to some other disease. It is probable this liability is owing to some morbid change in the structure of the part inappreciable by our present means of examination; in more distinct cases, when any part has been severely diseased, we never see a perfect restoration of its healthy structure and form. Even in those tissues that are most easily repaired, there is not an actual reproduction of the injured structure.

The period occupied in the progress of a disease to recovery or death is the basis of the chief division of acute and chronic diseases. The severity of the symptoms may in both cases be the same; but in general those of chronic cases are less prominent than those of acute cases.

When the disease terminates fatally, or when death takes place from any other cause at a distant period from its occurrence, we obtain perhaps the most valuable because the most certain part of pathological knowledge, that of the material effects which the morbid process has produced. This, the study of morbid anatomy, is often specially called pathology. By the examination of the altered parts and a comparison of the changes of structure which they present with those which are known by observation of external diseases or by experiment to result from certain leading morbid processes, as inflammation, &c., we are enabled to determine the nature of that which had existed beyond the limit of our senses, and thus to appreciate correctly the meaning of the several symptoms which had marked its progress during life, and the powers and modes of action of the circumstances to which it owes its origin. The practical value of such knowledge is the power which it affords of determining during life the nature of each disease, and the appropriate remedy for each.

PATINA, a name given to the rust or ærugo of coins and medals. Pinkerton (*Essay on Medals*, edit. 1789, vol. i., p. 163) says, 'nothing contributes so much to the conservation of brass or copper coins as that fine rust, appearing like varnish, which their lying in a particular soil occasions. Gold admits no rust but iron mould, when lying in a soil impregnated with iron. Silver takes many kinds, but chiefly green and red, which yield to vinegar. For in gold and silver the rust is prejudicial, and to be removed; whereas on brass and copper it is preservative and ornamental: a circumstance remarked by the antients, as the 'pocula adorandæ rubiginis' of Juvenal may prove, and that exquisite Greek phrase which terms patina *χάλκου ἄνθος*, 'the flower of brass.' This fine rust, which is indeed a natural varnish, not imitable by any power of human art, is sometimes a delicate blue, like that of a turquoise, sometimes of a bronze brown, equal to that observable in antient statues of bronze, and so highly prized; and sometimes of an exquisite green, a little on the azure hue, which last is the most beautiful of all. It is also found of a fine purple, of olive, and of a cream colour, or pale yellow: which last is exquisite, and shows the impression to as much advantage as paper of cream colour, used in all great foreign presses, does copper-plates and printing. The Neapolitan patina is of a light green; and, when free from excrescence or blemish, is very beautiful. Sometimes the purple patina gleams through an upper coat of another colour, with as fine effect as a variegated silk or gem. In a few instances a rust of deeper green is found; and it is sometimes spotted with the red or bronze shade, which gives it quite the appearance of the East Indian stone called blood-stone. These rusts are all, when the real production of time, as hard as the metal itself, and preserve it much better than any artificial varnish could have done, concealing at the same time not the most minute particle of the impression of the coin.'

PATKUL. [Charles XII.]

PATMOS, a small island, one of the Sporades, near the south-western coast of Asia Minor, and about 30 miles south of Samos. It is now called Patino. Patmos is chiefly known as having been, according to the early tradition of the Christian church, the place of exile of the apostle St. John, who is said to have written his *Revelations* there. The island is a continuous rock about 15 miles in circumference, rugged and barren, except a few fertile spots; the coast is high, and forms many capes, with several good harbours, of which the most frequented lies on the north-east side. The only town is situated on a high rocky eminence rising abruptly from the sea; it consists of about 400 houses, which, with about 50 more at La Scala, or the landing-place, are the only habitations in the island. In the middle of the town, and in the highest part of it, is the monastery of St. John, which was built by Alexius Comnenus. It is a massive building flanked with towers, and looks like a fortress. About half way up the mountain, between La Scala and the town, is a natural grotto, in which the natives say that St. John wrote his *Revelations*; and they have built a small church over it. (Tournefort; Hilaire, *Voyage dans la Grèce*.)

PATNA, the modern capital of Bahar, is situated on the south bank of the Ganges, in 25° 36′ N. lat. and 85° 15′ E. long. The city, within the walls, is about a mile and a half long, from east to west, and about three-quarters of a mile broad from north to south. This part of the city is very closely built, but the suburbs are of far greater extent, and the buildings altogether extend for nine miles along the Ganges, with a breadth of about two miles; but the buildings outside the walls are irregularly placed, and with considerable spaces between them. The greater part of the houses are of mud, the rest are built with brick, and nearly all the roofs are tiled, a few only being thatched. The number of houses, according to Dr. Buchanan Hamilton, was 52,000, in 1811, and the total population 312,000, about two-thirds of whom were Hindus, and the remainder Mohammedans; the number of Europeans is very small.

The city is the seat of a considerable banking trade. In 1811 there were 24 bankers established, several of whom had agents at the principal commercial cities of Hindustan. A considerable trade is also carried on in opium, rice, and saltpetre, as well as in cotton cloths and silk goods.

Patna is distant 155 miles from Benares, from Lucknow 316 miles, from Agra 544, and from Delhi 661 miles, as travelling distances.

PATRAS, the antient PATRÆ, a town on the north coast of the Morea, about six miles south-west of the entrance of the Gulf of Lepanto. It stands on a ridge about one mile long, of which the acropolis, or citadel, crowns the summit, and commands the view of a fine and fertile plain which stretches along the sea-coast. Mount Voidhia, one of the high summits of the Morea, rises above the ridge on which the town is built. The plain of Patras produces a great quantity of currants, which form an article of export. The hills are planted with vines, from which a good red wine is made. Many of the houses are surrounded by gardens, with orange, fig, pomegranate, and other fruit trees, [illegible] the houses themselves are ill built and mostly of wood. (Leake's *Morea*.) Previous to the Greek revolution, Patras was the most thriving town of the Morea, being the emporium of the trade of that peninsula as well as of western Greece. It contained about 10,000 inhabitants, mostly Greeks, and had consuls of most European nations. The war of the Greek revolution ruined the town; the citadel, which was in the hands of the Turks was repeatedly attacked, but never taken by the Greeks, and it capitulated at last, in 1828, to the French auxiliary force. Since that time Patras has somewhat recovered; and it is said to contain at present about 8000 inhabitants. The eparchy or district of Patras contains 112 villages besides the town.

Patrae was one of the twelve cities of Ægialeian Ionia, or Achaia, and is the only one that still exists as a town. [ACHAIA.] After the battle of Actium, Augustus sent a colony to Patrae. The present town occupies the same site as the old one, but few remains of antiquity are visible, except some statues in the acropolis, which are noticed by Leake.

PATRIARCH (*πατριάρχης*, the head of a family), a title given to the heads of families in the early history of the human race, and more particularly to the ancestors of the people of Israel down to the time of Moses, and especially applied to the twelve sons of Jacob, as the ancestors of the twelve tribes of Israel.

There is a book in existence entitled 'The Testaments of the Twelve Patriarchs, the Sons of Jacob,' containing what profess to be the dying admonitions of the patriarchs to their children, and their predictions of the future fortunes of their descendants. This work has been published in Greek by Grabe, from MSS. in the universities of Oxford and Cambridge (*Spicileg. Patr.*, tom. i., p. 129), and again by Fabricius (*Cod. Pseudepigr. Vet. Test.*, 1713, p. 496); it was translated into Latin by Grosthead, bishop of Lincoln (8vo., Haganoæ, 1532), into French by Francis Mace, and into English by Whiston, in 'A Collection of Records belonging to the Old and New Testament,' London, 1727-8. Whiston has a dissertation to prove the authenticity of the work, but his arguments are neither worth repeating nor refuting. It is undoubtedly spurious. There is no evidence to prove that it ever existed in Hebrew, and the earliest reference to it by any ancient writer is one by Origen, who expressly asserts that it formed no part of the canon. It contains allusions to and quotations from passages both in the Old and New Testament, and the writer evinces an amount of knowledge of Christianity which was not possessed even by Christians till some time after the ascension of Christ, much less by the twelve sons of Jacob. Lardner, who has a very good notice of the work (*Credibility*, pt. ii., ch. xxix., s. 2), gives the following summary of the allusions to Christianity contained in the work:—'Thus this author, in an indirect manner and in a pretended prophetical style, bears a large testimony to the Christian religion, to the facts, principles, and books of the New Testament. He speaks of the nativity of Christ, the meekness and unblameableness of his life, his crucifixion at the instigation of the Jewish priests, the wonderful concomitants of his death, his resurrection, and ascension. He represents the character of the Messiah as God and man, the Most High God with men, eating and drinking with them, the Son of God, the Saviour of the world, of the Gentiles, and Israel, as eternal high priest and king. He likewise speaks of the effusion of the Holy Spirit upon the Messiah, attended with a voice from heaven; his unrighteous treatment by the Jews, and their desolations and the destruction of the Temple upon that account; the call of the Gentiles; the illuminating them generally with new light; the effusion of the Spirit upon believers, but especially, and in a more abundant measure, upon the Gentiles. Here is little notice taken of our Lord's miracles: however, he speaks of the Messiah as a "man who renews the law in the power of the Most High," in which expressions the working of miracles seems to be implied. Here are also passages which seem to contain allusions to the gospels of St. Matthew, St. Luke, and St. John, the Acts of the Apostles, the Epistle to the Ephesians, first to the Thessalonians, first to Timothy, the Epistle to the Hebrews, the first Epistle of St. John, and the book of the Revelation; and, as far as was consistent with his assumed character, the author declares the canonical authority of the Acts of the Apostles and the Epistles of St. Paul. Lastly, he recommends the reading of the Holy Scriptures.' (Lardner's *Works*, vol. ii., p. 363, ed. of 1831.) In a passage in the Testament of Benjamin (sec. 9) the prediction in *Gen.*, xlix. 27, seems to be applied to the apostle Paul. Others of the early Christian writers also apply that text to Paul. In these Testaments the canonical Scriptures are never quoted by name. The only books which are so quoted are the 'Scripture of Enoch, the Tables of Heaven' [ENOCH], and the 'Scripture of our Fathers.'

The author of this book was probably a converted Jew, though not, as Cave supposed, a Judaizing Christian. It seems to have been written about the end of the second century.

PATRIARCH, in Church History, was the ecclesiastical chief of a diocese, which included several provinces. It is not known at what time this title was introduced into the church; but before the fourth century the bishops of Rome, Antioch, and Alexandria, had obtained a degree of preeminence over the other bishops. In the time of Constantine the Great the bishop of Constantinople was made to rank with the three just mentioned; and either then or not long after, the title of patriarch was given to these four prelates. The number of these dignitaries was increased in the fifth century. The patriarch of Constantinople reduced under his jurisdiction those of Antioch and Alexandria, and obtained the title of 'Universal Patriarch.' The bishop of Rome was called '*Prince of the Patriarchs*.' The struggles of the patriarchs of Rome and Constantinople for supremacy was the chief cause of the separation between the Eastern and Western churches.

The powers of the patriarchs are thus described by Mosheim:—'They alone consecrated the bishops who lived in the provinces that belonged to their jurisdiction. They assembled yearly in council the clergy of their respective districts, in order to regulate the affairs of the church. The cognizance of all important causes, and the determination of the more weighty controversies, were referred to the patriarch of the province where they arose. They also pronounced a decisive judgment in those cases where accusations were brought against bishops. And lastly, they appointed vicars, or deputies, clothed with their authority, for the preservation of order and tranquillity in the remoter provinces.' (Mosheim, *Ecc. Hist.*, Cent. v., pt. ii., chap. 2.) There were however provinces of the empire which were exempt from their jurisdiction.

The Greek church is at present governed by four patriarchs, namely, those of Constantinople, Jerusalem, Antioch, and Alexandria.

PATRICIANS (*Patres, Patricii*, in Latin) was the appellation of the members of the original houses or gentes, of which the Roman populus, the ruling power in the community, was at first composed, and of their descendants, either by blood or adoption. The houses are said to have been three hundred. Each house became subdivided into several families, which were distinguished by a surname, in addition to the name of the gens, which was common to all, like that of a Scottish clan. Thus the gens Cornelia comprised the families of the Scipiones, the Lentuli, the Sullæ, &c. The families composing a gens were not necessarily related by consanguinity, for individuals might be adopted into a gens. The definition of a gens by Scaevola (Cic., *Top.*, c. 6) is, that the members bore a common name, were descended from freemen, without any stain of slavery among their ancestors, and had never incurred any legal disability; they had common sacred rites, or sacrifices appointed for stated days and places. When a family became extinct by default of heirs in the male line, its property reverted to the gens of which it formed a part. Gentile and patrician were therefore synonymous. Freedmen and their descendants belonged to the gens of which they bore the name, but they had not the rights of the gens, that is to say, the gentile rights. Natives of the confederate towns of Latium coming to settle at Rome attached themselves to some gentile family, the head of which was styled their patron, and they were styled his clients. [CLIENT.]

The members of the senate, the consuls, and the pontiffs were, in the first ages of the republic, chosen exclusively from among the patricians, until the year 365 B.C., when Licinius carried his rogations, by which the plebeians were admitted to the consulship, as well as to the custody of the Sibylline or sacred books. [LICINIUS STOLO.]

When the plebeians became eligible to all the offices of the state, a new nobility was formed, consisting of those who had filled the offices of consul, prætor, or curule ædile, and this nobility was transmitted to their posterity with the 'Jus imaginum,' or the right of setting up in their houses the images of their ancestors. Still a distinction in opinion continued to prevail in favour of the patricians, or older nobility, as distinguished the plebeian from families.

When Constantine transferred the seat of the empire to his new city, he established there a new senate and a new patrician order, the members of which were appointed by the emperor. After the fall of the Western Empire, the officers sent by the Byzantine emperors to administer the provinces of Italy subject to them, were chosen from among the patricians of Constantinople. Thus we read in the history of the dark ages, of the 'patrician of Rome,' meaning the governor or representative of the Eastern emperor in that city, and the title was afterwards assumed by Charlemagne and his successors.

At Venice the name of patrician was given to the members of the great council, or supreme legislature, and their descendants, and their names were registered in the golden book. After the decree of February, 1297, called 'La serrata del maggior consiglio,' no new member was introduced into the council, but all descendants of those who had once sat in the great council, on arriving at twenty-five years of age, were by right members of the sovereign assembly, and patricians of Venice. 'Patrizio Veneto' was a title of nobility, considered equal to that of any feudal noble not of a sovereign house.

In other parts of Italy, such as Genoa and Rome, the word patrician was and is still used in common language to denote a member of the hereditary nobility, independently of any feudal title.

PATRICK, SIMON, born 1626, died 1707, a prelate of the English church, distinguished as the author of many excellent works in practical divinity and expository theology. He was a native of the town of Gainsborough, educated in Queen's College, Cambridge, and the chief scene of his public labours as a clergyman was the parish of Saint Paul's, Covent Garden, of which he was rector, till higher preferment was bestowed upon him; he became dean of Peterborough in 1679, bishop of Chichester in 1689, and bishop of Ely in 1691.

The titles of his writings will show at once their nature and tendency to have been to promote Christian piety and to foster the spirit of devotion. In their day they were much esteemed, and they are still valued as among the best helps to devotion by good and pious Christians: 'Heart's Ease,' 'Parable of the Pilgrim,' 'Exposition of the Ten Commandments,' 'The Friendly Debate,' 'The Christian Sacrifice,' 'The Devout Christian,' 'Advice to a Friend,' 'Jesus and the Resurrection justified,' 'The Glorious Epiphany.' Beside these, there are his Paraphrase and Comments on the books of the Old Testament, which have been several times reprinted.

These writings are the foundation of Bishop Patrick's reputation. He also completed and published Gunton's 'History of the Church of Peterborough.'

PATRICK, ST., the apostle of Ireland, was born, according to Usher and Tillemont, in the year 372. The former places his death in 493, but Tillemont about the year 455. Nennius, published by Gale, says he died fifty-seven years before the birth of St. Columba, consequently in 464.

The two principal antient Lives of St. Patrick are, that compiled by Jocelin, a Cistercian monk, in the twelfth century, who quotes four lives written by disciples of the saint; and that by Probus, who, according to the Bollandists, lived in the seventh century. In both, legendary tales are intermixed. The chief authentic information we possess concerning this saint is obtained from his own writings, his 'Confession,' and a letter which he addressed to Corotic, a prince in some part of Wales, after the Britons had been abandoned by the Romans, who made a descent upon Ireland during St. Patrick's mission to that country. From the 'Confession' we learn that he was born in a village called Bonaven Taberniæ, supposed to be the town of Kilpatrick at the mouth of the Clyde in Scotland, between Dumbarton and Glasgow. He calls himself both a Briton and a Roman, meaning of mixed extraction; and says his father was of a good family, named Calphurnius. His mother was Concha, or Conchessa, who, according to some writers, was niece to St. Martin of Tours. According to Nennius (abbot of Bangor, A.D. 620), St. Patrick's original name was Maur; that of Patricius was given to him by Pope Celestine when he consecrated him a bishop, and sent him as a missionary into Ireland, A.D. 433.

Jones, in his 'Historical Account of the Welsh Bards,' fol., Lond., 1794, p. 13, says St. Patrick was born in the vale of Rhos in Pembrokeshire.

His festival is marked on the 17th of March in the Martyrology of Bede.

(See the *Acta Sanctorum* of the Bollandists, 'Month of March,' vol. ii., p. 517-592; Butler's *Lives of the Saints*, 8vo., Dublin, 1779, vol. iii., p. 176-186.)

PATRIMONY OF ST. PETER. [VITERBO.]

PATRI'NIA, a genus of plants of the natural family of Valerianeæ, consisting of a few species found in Siberia, China, and Japan, and to which the long-famed spikenard of the East was referred by Mr. Dora, but which has been formed into a new genus, *Nardostachys*. [SPIKENARD; SWEET CANE.]

PATRISTIC THEOLOGY. [THEOLOGY.]

PATRON. [BENEFICE; PARISH.]

PATRO'NUS, derived from *pater*, a 'father,' as *materna* is formed from *mater*, a 'mother.' The relation of Patron and Client (*cliens*) in antient Rome is discussed in the article CLIENS; but the relation between a freedman (*libertus*) and his patronus requires a few words of explanation.

In the Roman polity persons were divided, with respect to status or condition, into freemen (*liberi*) and slaves (*servi*). Freemen were again divided into persons who were born in a state of freedom (*ingenui*), and those who had been manumitted (*libertini*). A manumitted slave was called *libertus*, that is, *liberatus*, 'freed,' and his master who manumitted him became his *patronus*. The slave who was manumitted received the gentile name of his patronus (Lactant., iv. 3); and accordingly we read of a freedman of Pompey called Pompeius Lenæus (Plin., *Hist. Nat.*, xxv. 3), and of a freedman of Cicero called Laurea Tullius (Plin., *Hist. Nat.*, xxxi. 3), and of another called Tullius Tiro, who is frequently mentioned in Cicero's letters. The relation between patronus and libertus resembled in many respects that between patronus and cliens; but it appears that their mutual rights and obligations were rather regulated by public opinion than fixed by any positive enactment. The patronus on the one hand was bound to take the libertus under his protection; and the libertus on his part was bound to assist his patronus by every means in his power, but the only case in which he was compelled by the law to do so, was when the patronus or his children had become too poor to support themselves. In such a case, if the patronus or his children proved to the satisfaction of the governor of the province (*præses*) their necessitous condition, he or they received from their libertus a sum of money every month for his or their support. (*Dig.* xxv., tit. 3, s. 9.)

The most important part however of the connection between the patronus and the libertus was the right which the former had in certain cases to the property or a portion of the property of the latter upon his death. This right was founded upon the fact, that the law regarded the patroni as the adgnati of their liberti, and consequently they succeeded to the property like any other adgnati. By a law of the Twelve Tables, if the libertus died intestate and left no heir (*suus heres*), the patronus succeeded to his property. (Gaius, iii. 40; Justinian, *Institut.*, iii., tit. 7, s. 1.) If the heir was a son born of his own body (*naturalis*), no one had a right to complain; but it appeared to the Romans a great injustice that an adopted son or daughter, or a wife (*in manu*), should deprive the patron of his right to the property. This injustice was remedied by the prætor's edict, by which it was regulated that natural sons, whether in the power of their father at the time of his death, or whether they had been emancipated or adopted by another person, provided they had not been disinherited, should alone be a bar to the patron's right to the property, and that if a libertus who had no natural sons made a will, he was obliged to leave half of his property to his patronus; and if he left none of his property, or less than half, the bonorum possessio of half was given to the patronus, even against the words of the will; if the libertus died intestate leaving an adopted son, a wife (*in manu*), or a daughter-in-

[illegible] *filii quasi*, half of the property was also given to the patronus. (Gaius, iii. 40, 41; *Institut.*, iii., tit. 7, s. 1; Ulp., *Fr.* xxvii. 1; Dion Cass., li. 15.)

By the Lex Papia the rights of patrons to the property of their rich freedmen were still further increased. By this law it was enacted, that if a libertus died leaving property to the value of 100,000 sesterces, a portion of his property (*virilis pars*) went to his patronus, whether he had made a will or died intestate, provided he had fewer than three children. If he left only one son or one daughter, half of his property went to his patronus, as if he had died leaving no son or daughter; if he left two children, a third went to the patronus, but if three, the patronus had no claim to any portion. (Gaius, iii. 42; *Institut.*, iii., tit. 7, s. 2.)

With regard however to the property of a liberta, the ancient law sufficiently protected the rights of the patronus, and he therefore had no occasion to have recourse to the edict of the prætor. For since the patronus was the tutor of the liberta, she could not make a will without his consent and consequently could not leave her property to any one else. (Gaius, iii. 43; Ulp., *Fr.* xxix. 2.) The Lex Papia however set free a liberta who had brought forth four children from the tutela of her patronus. (Gaius, iii. 44; Ulp., *Fr.* xxix. 3.)

The patrona, previous to the passing of the Lex Papia, only had the same right to the property of the libertus as was granted to the patronus by the Twelve Tables, and could not, like the patronus, obtain by the prætor's edict the half of the property of a libertus who had left only an adopted son or a wife or daughter-in-law. By the Lex Papia however, an ingenua patrona, who had brought forth two children, and a libertina patrona, who had brought forth three, obtained almost the same rights as the patronus possessed by the prætor's edict; and an ingenua patrona who had brought forth three children obtained the same privileges as were given to the patronus by that law; but a libertina patrona in no case obtained the rights granted to the patronus by the same law. (Gaius, iii. 49, 50; Ulp., *Fr.* xxix. 5, 6.)

The rights of a patronus to the property of a libertus only extended to his direct heredes, sons, grandsons, great-grandsons, &c., and never belonged to his collateral heirs (*extranei heredes*). (Gaius, iii. 58.) A patronus was able to assign a libertus (*adsignare libertum*) to one of his sons to the exclusion of his other children, so that on the death of a libertus, the son to whom the libertus had been assigned was alone entitled to the property, which was due to the patronus by the jus patronatus. (*Institut.*, iii., tit. 8; *Dig.*, 38, tit. 16, s. 107.)

All the preceding remarks respecting the succession of the patronus to the property of the libertus, only apply to the property of those liberti who were Roman citizens. Those liberti who were Latini [LATINUM JUS], or Dediticii, had in fact no power over the disposal of their property. The Latini liberti had the privileges of freemen while alive, but 'they lost their life and their liberty at the same time,' and their property, like the *peculia* of slaves, came by the Lex Junia to the persons who had manumitted them (Gaius, iii. 56; *Institut.*, iii., tit. 7, s. 4.) The succession to the property of the liberti Latini differed also in many other important particulars, which Gaius has pointed out (iii. 57-62), from the succession to the property of those liberti who were Roman citizens. By a decree of the senate passed in the reign of Claudius during the consulship of Lupus and Largus, it was enacted that the property of the Latini should pass first to those who had manumitted them and their children not disinherited by name, and afterwards to their proper heirs. (Gaius, iii. 63; *Institut.*, iii., tit. 7, s. 4.) By a constitution of Trajan, it was enacted that if a Latin libertus obtained from the emperor the jus Quiritium without the knowledge or against the will of his patronus, he should enjoy the privileges of a Roman citizen while he lived, but should be regarded as a Latinus at the time of his death, and should have no power of leaving his children as his heredes; and that he should only be allowed to make a will so far as to leave his patronus his heir, or if the latter were unwilling to become his heir, of substituting another in his place. (Gaius, iii. 72.) This constitution however was a little altered by one of Hadrian, who gave with certain conditions the same privileges to those Latini who had obtained the jus Quiritium from the emperor, as if they had obtained it by a decree of the senate or the Lex Ælia Sentia. (Gaius, iii. 73.)

These laws were however very much altered by Justinian. He gave to the liberti Latini and Dediticii the same privileges as those liberti possessed who were Roman citizens. He also enacted, that if a libertus or liberta left less property than amounted to the value of 100 aurei, the patronus had no claim to any portion of the property, provided they made a will; but if they died intestate, leaving no children, then the patronus succeeded to the property by the law of the Twelve Tables. If the property of the libertus or liberta was of more value than 100 aurei, and they left children, the patronus had also no claim to any part of the property; but if those liberti or libertæ who left no children died intestate, the patronus succeeded to the whole of the property, and if they made a will without leaving any part of their property to the patronus, then he had a right to a third of the property, and not to a half, as was formerly the case. (*Institut.*, iii., tit. 7, s. 3.)

(Gaius, iii. 39-76; Ulpian, *Fragm.*, xxvii. 1-5; xxviii. 7; xxix. 1-7; *Institutiones*, iii., tit. 7, *De Successione Libertorum*; tit. 8, *De Adsignatione Libertorum*; *Digest* 37, tit. 14, *De Jure Patronatus*; 38, tit. 2, *De Bonis Libertorum*; 38, tit. 4, *De Adsignandis Libertis*; *Collatio Legum Mosaic. et Roman.*, xvi, 8, 9; Unterholzner, *Ueber das patronatische Erbrecht*, in the *Zeitschrift für Geschichtliche Rechtswissenschaft*, 5th vol., 1st part, Berlin, 1823; and the articles CLIENS, LATINUM JUS, and LIBERTINUS, in this work.)

PATRO'NYMIC (*πατρωνυμικόν*) is a name given by grammarians to those words which express the name of a person's father or ancestor. Thus Achilles is called Pelides (the son of Peleus), Agamemnon is styled Atrides (the son of Atreus), &c. In the English language we have no words of this description, but in Sanscrit and Greek they are very common, especially in Sanscrit, which has as many as thirteen different terminations to form such words, namely, *a, âki, âyana, âyani, âyanya, ineya, iya, îya, êra, aira, [illegible], ki, ya*. In Greek the most common masculine termination is *ides*, as *Cecrop-ides*, a descendant of Cecrops; some patronymics are formed by adding *ion*, as *Kron-ion*, the son of *Kronos*, &c. Feminine patronymics in Greek are commonly formed by adding *id* (in the nominative *is*), as *Tantal-is*, gen. *Tantal-id-os*, the daughter of Tantalus. In Lithuanian some patronymics are formed by adding *na*, as *Janow-na*, the son of Janow or John (Pott's *Etymologische Forschungen*, vol. ii., p. 579); which termination may perhaps be connected with the Latin *anus*, which forms such patronymics as *Octavi-anus*, one of the family of Octavius, *Æmili-anus*, one of the family of Æmilius, &c.

PATTERNS. Connected with the subject of patents is the copyright of designs. By a recent Act of parliament (2 Vic., c. 17), the inventor or purchaser or proprietor of any design, 'for a pattern or print to be either worked into, or worked on, or printed on, or painted on, any article of manufacture being a tissue or textile fabric; or for the modelling, or the casting, or the embossing, or the chasing, or the engraving, or for any other kind of impression or ornament on any article of manufacture; or for the shape or configuration of any article of manufacture,' may secure the sole use and benefit of such design to himself for twelve months, and if it be applied to metal work, for three years.

He must take or send to the office of the Registry of Designs, Wellington-street North, Strand, three copies or drawings of his design; one of which will be filed by the registrar, a second left at the disposal of the Board of Trade, and the third returned to the party registering, with a certificate, which certificate is by the Act held to be evidence of registration.

Every article manufactured according to such design must have thereon the name of the first registered proprietor, the number of the design in the register, and the date of the registration.

Any person pirating a design thus protected is liable to a penalty of from 5*l.* to 30*l.* for each offence, which may be recovered by an action at law, or by summary proceeding before two magistrates.

Registered designs may be transferred from one person to another, in which case the latter is entitled to be registered as the proprietor. Printed forms of such transferences are supplied at the office.

The following are the fees ordered to be paid by the comsury:—For registering each design, including certificate, 1*l.* 1*s.*; if metallic substances, 3*l.* 3*s.*; for each folio page of the certificate after the first, 5*s.*; in case of loss of certificate, transfer of design, demand for search, &c., search for design, 5*s.*; registering transfer of design, either total or partial, 1*l.* 1*s.*; certifying design subsequent to registration, 1*l.* 1*s.*

This Act applies to designs for all sorts of fabrics and manufactures, with the exception of lace and those provided for under the calico printers' Acts, 27 Geo. III., c. 38; 29 Geo. III., c. 19; 34 Geo. III., c. 23; 2 Vic., c. 13. By these Acts the inventor of a new pattern may restrain any one from copying his design for three months, by printing or stamping his name upon the end of each piece of the fabric.

All communications with the Office for Registration of Designs, including the designs themselves, pass free through the General Post, whatever may be their weight. The fees or a money-order may be sent and the certificate received in the same manner free of all expense.

PATTI. [MESSINA.]

PATUXENT. [MARYLAND.]

PATZCUARO. [MEXICAN STATES.]

PAU, a town in the south of France, capital of the department of Basses Pyrénées: it is on the right bank of the Gave de Pau, above 400 miles in a direct line west-south-west of Paris, or 497 miles by the road through Orléans, Limoges, Bordeaux, Roquefort, and Aire; in 43° 18′ N. lat. and 0° 23′ W. long.

Pau owes its origin to a castle erected here by the princes of Béarn, in the ninth or tenth century, as a place of security from the hostilities of the Saracens. The intended site of the castle was marked out with stakes, and from the Béarnais word *paou* (in French *pieu*), a stake, the town takes its name. It sprung up and increased gradually under the shelter of the castle, which continued to be the residence of the princes of Béarn until the accession of Henri IV. to the throne of France. Louis XIII. established a parliament in the town, and Louis XIV. founded a university, but it never attained any degree of celebrity. The town is situated on a height, and is divided into two parts by a deep ravine crossed by a bridge: the principal part of the town is on the south side of the ravine. There is a suburb, called 'the Lower Town,' on the bank of the Gave de Pau, at the foot of the height on which the town stands. Pau is well laid out; the houses are tolerably well built, and are covered with a thick coating of mortar or cement. The poorer houses in the suburbs are chiefly of pebbles laid in very hard mortar. The principal object of interest is the castle, the birthplace of Henri IV., on the west side of the town. This building, which was erected in place of the original castle of the Béarnais princes, is an irregular Gothic structure, striking from its vastness and interesting from its historical associations. It is kept in repair by the government. The room in which Henri was born and the tortoise-shell which served for his cradle are still shown. The castle commands a beautiful and extensive prospect, and has a fine park attached to it. There are two places or squares in Pau, that of La Comédie, the larger and finer of the two, and the Place Royale, planted with trees and adorned with a fine pedestrian statue of Henri IV. in bronze.[*] There are also several promenades.

There is a good bridge over the Gave de Pau, communicating between the suburb of 'the Lower Town' and the neighbouring town of Jurançon, celebrated for its wines. There are a court-house, a market-house, with a fountain in front of it, and several promenades. The population of Pau in 1831 was 10,597 for the town, or 11,285 for the whole commune; in 1836, 12,607 for the whole commune. The principal branches of industry are the manufacture of carpets and of linens, especially table-linen and Béarnais handkerchiefs, dyeing, and tanning. Trade is carried on in hams, salted legs of geese, and other provisions, wines, cotton yarn, cotton goods, and coarse woollens. There are two good weekly markets and three yearly fairs.

Pau has several fiscal government offices, a Cour Royale, or court of justice, having jurisdiction over the three departments of Basses Pyrénées, Hautes Pyrénées, and Landes; an Académie Universitaire, whose circuit is coextensive with the jurisdiction of the Cour Royale; a royal college, with a museum and a collection of philosophical instruments, a public library of 14,000 volumes, a collection of pictures, a drawing-school, an agricultural society, a theatre, and public baths.

Pau was the birthplace of the Jesuit Pardies, a good geometrician and astronomer; and of Bernadotte, the present king of Sweden.

The arrondissement of Pau comprehends an area of 6[illegible] square miles: it is divided into eleven cantons or districts, each under a justice of the peace; and comprehends 204 communes, with a population, in 1831, of 117,865; in 1836, 122,404.

PAUL, ST., the great Apostle of the Gentiles, originally called Saul, was born at Tarsus in Cilicia. Though a Jew of the tribe of Benjamin, and a Pharisee of the most rigid sect, he was by birth a Roman citizen, a privilege inherited from his ancestors, upon some of whom it had been conferred for services rendered to the state. (Lardner.) The year of his nativity is not known. He was present at the martyrdom of Stephen, A.D. 34, on which occasion he is first introduced to our notice, and is called a young man. He learned the art of tent-making, not with the intention of making it the occupation of his life, but because it was a custom among the Jews to instruct their youth, even of the highest respectability, in some mechanical art. Having been educated in the learning of the times, for which Tarsus was then highly celebrated (Strabo, p. 673. Casaub.), and in which he undoubtedly made great proficiency, he went to Jerusalem to study the laws and traditions of his people under Gamaliel, a distinguished Rabbi. Being a man of great talent, ardent mind, and inflexible resolution, and being devotedly attached to the institutions of his country, whose origin and antiquity alike impressed and fascinated his imagination, he contemplated with alarm and anxiety the progress of the new religion. Accordingly he took an active and prominent part against the Christians, and pursued them with such zeal and unrelenting fury, that his conduct towards them is described as 'breathing out threatenings and slaughter.' He obtained letters from the Sanhedrim to the synagogue of the Jews at Damascus, and also to the governor, authorising him to apprehend and bring to Jerusalem whomsoever of the disciples he might find there. While on his journey for this purpose his miraculous conversion took place, the particulars of which are recorded in the ninth chapter of the 'Acts of the Apostles.' This event, so important in its results upon the subsequent fortunes of Christianity, occurred A.D. 35, two years after the crucifixion of our Lord.

After his baptism at Damascus he went into Arabia. In A.D. 38 we find him again at Damascus; and from that place, as likewise from Jerusalem shortly after, he was compelled to escape secretly and by night, in consequence of the perseverance with which the Jews sought his life, for preaching with so much boldness and success the religion which he once laboured to destroy. From Jerusalem he retired to Tarsus, his native city, and was employed for some years in propagating the faith through the neighbouring regions of Syria and Cilicia. Up to this time the preaching of St. Paul and of the other apostles had been confined to the Jews; but the conversion of Cornelius, a gentile, was a very significant indication that Christianity was intended not for one country or one people, but for all mankind without distinction of race or nation. This was the conclusion inferred both by the apostles and the Jewish converts at Jerusalem. Immediately therefore the object of their mission was extended; and instead of being restricted to the children of Abraham, now comprehended all mankind. Into this great idea, that of founding a religion for the entire human race, St. Paul entered with all the ardour and devotion which characterised his mind. He departed from Tarsus A.D. 42; and in conjunction with Barnabas, who had been sent from Jerusalem for the purpose, preached to the gentiles at Antioch with the greatest success. But the views he had formed of Christianity as a universal religion suggested to him the propriety of enlarging the sphere of his labours, and of carrying the gospel to more remote provinces. To this work he and Barnabas were divinely a-pointed (*Acts*, xiii.); and he commenced his first apostolic journey A.D. 45, ten years after his conversion. In company with Barnabas and Mark the evangelist, he sailed from Seleucia, and successively visited Salamis and Paphos in the Isle of Cyprus; Perga in Pamphylia, and Antioch in Pisidia; Iconium, Lystra, and Derbe, in Lycaonia; and made converts and founded churches in those places. At the end of two years he returned to Antioch in Syria. While at Antioch he was engaged in a most important controversy with some Jewish Christians, who asserted that circumcision was necessary to be observed by converts to the new faith. St. Paul on the other hand, contended that Christianity entirely superseded the Mosaic Law, and required conformity to none of its rites. The question was referred to a council of apostles and elders at Jerusalem, who, after much deliberation, decided in favour of the view which St. Paul had taken. The decision was declared to have received the sanction of the Holy Ghost, and it was communicated to the gentile converts at Antioch and other places.

---

[*] This statue replaces one of Louis XIV. erected by the ministers of that prince. The townsmen wished for the statue of Henry IV., but not being able to obtain their wish, took their revenge by inscribing, in the Béarnais dialect, on the pedestal of the statue of Louis, 'This is the grandson of our great Henri.' This statue was destroyed at the Revolution. The castle was much damaged at that period, and subsequently occupied as a barrack and a prison, until the restoration of the Bourbons.

In the year 50, St. Paul commenced his second apostolic journey. Leaving Antioch, and passing through Syria and Cilicia, he traversed the whole extent of Asia Minor, and came to Troas. From Troas, in obedience to the direction of a vision, he sailed over into Europe; and after preaching the gospel at Philippi, Thessalonica, Beræa, and Athens, arrived at Corinth, where he abode a year and a half, and was eminently successful in establishing an important Christian community in that learned, wealthy, and voluptuous city. From Corinth he sailed to Ephesus, and thence to Cæsarea; and taking Jerusalem in his way, returned to Antioch, A.D. 53. During this journey he wrote his two Epistles to the Thessalonians, and his Epistle to the Galatians; the two former, and probably the latter, from Corinth.

Having remained a short time at Antioch, he set out upon his third and last apostolic journey, A.D. 54. He visited the churches in Galatia and Phrygia, and thence came to Ephesus, where he lived about two years. Here and in the neighbouring district of Asia Minor he preached the gospel with so much success, that not only were great numbers converted to Christianity, but those who practised incantations and magical arts and other gross superstitions, for which Ephesus was notorious, renounced their practices, burnt their books and divining instruments, and professed their faith in the new religion. After the disturbance raised by Demetrius the silversmith, of which an account is given in the 19th chapter of the 'Acts,' the Apostle deemed it prudent to leave Ephesus. He went to Troas, and thence passed over into Europe, visiting the churches which he had planted in Macedonia and Greece. From Corinth, where he remained about three months, he returned by Macedonia to Asia; and taking an affectionate farewell of the elders of the Ephesian church at Miletus, embarked for Cæsarea, and terminated his journey at Jerusalem, A.D. 58. On this journey he wrote his first Epistle to the Corinthians, from Ephesus; his first Epistle to Timothy, the one to Titus and the second to the Corinthians, from Macedonia; and his Epistle to the Romans, from Corinth. These journeys occupied him about thirteen years.

While St. Paul was at Jerusalem, some Asiatic Jews, seeing him in the Temple, endeavoured to excite the populace against him by denouncing him as a dangerous and destructive agitator, who was aiming to abolish all distinction between Jew and gentile, teaching things contrary to the Law of Moses, and polluting the holy Temple by introducing the uncircumcised heathen within its precincts. The mob, aroused by this appeal to their passions and their prejudices, would undoubtedly have murdered the Apostle, had he not been rescued by the officer of the Temple guard. The subsequent events—his examination before the Sanhedrim, his defence before Felix and Agrippa, his long confinement at Cæsarea, his appealing to the emperor, and his arrival at Rome, A.D. 61, after a most tempestuous passage, are circumstantially related in the latter chapters of the *Acts*. He remained in Rome, in his own hired house, under the custody of a soldier, for two years; and wrote his Epistles to the Ephesians, Philippians, Colossians, Hebrews, and to Philemon. The Scripture history here leaves him; but it is probable that after his first imprisonment at Rome, which terminated A.D. 63, he visited Judæa, Asia Minor, and Macedonia, and returned to Rome A.D. 65, where he was imprisoned a second time. 'Knowing his departure to be at hand,' he wrote his second Epistle to Timothy; and it is supposed he suffered martyrdom, A.D. 66.

St. Paul was an extraordinary man, and peculiarly fitted for the times in which he lived and the mission to which he was called. He was accomplished in all the learning of the age; was brought up at the feet of one of the most skilful jurists of the East; possessed a powerful intellect, which was cultivated with the greatest care; was strong in feeling, firm in resolution, quick in perception, and sound in the decisions of his judgment. He had too much penetration to be himself easily deceived, and too much honesty to attempt to deceive others. His devoted attachment to the old and time-honoured institutions of his nation, and the zeal and ability he displayed in their defence; his ambition, mental power, and restless activity; and the well-grounded apprehensions with which the preaching of Jesus and his disciples had filled the imaginations of many, and which he alone seemed competent to dissipate, combined to make him an object of general attention to his countrymen, and prepare for him a career of distinction and emolument. His conversion, therefore, which involved the loss of all his brilliant prospects, has, next to the miracles and resurrection of our Lord, been justly contemplated as one of the most striking and memorable events connected with the early history of Christianity. So deeply impressed was Lord Lyttelton with its importance, that he considered it a sufficient demonstration of the divine authority of the religion to which the Apostle was a convert; and with this view he wrote his 'Observations on the Conversion of St. Paul.'

From being a furious zealot, a fierce and unrelenting persecutor of the disciples of Jesus Christ, St. Paul became a disciple himself, and a most energetic advocate of the faith which he had once attempted to destroy. After his conversion St. Paul was indefatigable in preaching the gospel. His perseverance never tired, his courage was never daunted. He was the main instrument of carrying the Christian religion among the Gentiles; and in this mission his labours were continued through a period of many years, and spread over a territory of vast extent. Judæa, Syria, and especially Asia Minor were filled with monuments of his zeal. He also passed over into Europe, where he made converts and planted churches. In this righteous cause he was deterred by no difficulties and no persecutions. He groups together in one passage the dangers which he had encountered: he speaks of toils, stripes, prisons, deaths; of being stoned and shipwrecked; of perils in the city and in the wilderness, on dry land and on the ocean, from false friends and open foes; of watchings and weariness, of hunger and thirst, of cold and nakedness. 'We see him,' says Paley, 'in the prosecution of his purpose, travelling from country to country, enduring every species of hardship, assaulted by the populace, punished by the magistrates, scourged, beat, stoned, left for dead; expecting wherever he came the same treatment; yet, when driven from one city, preaching in the next; unsubdued by anxiety, want, labour, persecution, and the prospect of death.'

The exertions of this great Apostle in the cause of Christianity were not confined to bodily toil and personal instruction. He was the author of fourteen epistles to individuals, and to churches, on various points of Christian doctrine, practice, and discipline. These epistles constitute a very considerable and most important part of the New Testament. They show him to be a man of great genius and great abilities; of clear conception, fervid imagination, lofty intellect, and a large and liberal heart. His style is strong and animated; unlaboured and without artifice in its construction; often broken and abrupt; it abounds in transitions, and brief and rapid allusion to existing errors, practices, and habits of thought, from which he draws the most apt illustrations. He addresses, by turns, the intellect, the imagination, the passions, the heart. He unites a severe logic with the noblest eloquence. The loftiest truths are made subservient to the most sober, pure, and rational morality; a morality essentially practical, and admirably adapted to human character and human circumstances. If he exhorts, it is with intense earnestness; if he reproves, it is in the spirit of sympathy and kindness; and whether he reasons, or advises, or admonishes, or consoles, a manly gravity and seriousness pervade his thoughts. Full of the dignity and grandeur of his subject, his ideas flow from him with irresistible rapidity; and borne along by the sublimity of his theme and the vastness of his conceptions, he stays not to arrange his words and adorn his periods. His arguments carry conviction to the mind of his reader; sometimes disclosing in a few words the profoundest views of Christian truth. His appeals to the passions are equally effective. Hope and fear are important springs of human action; to these he addresses himself, as well as to the reason; not by cold speculation on abstract fitnesses, but by the solemn infallibilities of a resurrection from the dead to an eternity of happiness or misery. With a like mastery and success he interests the affections and the higher moral faculties. Though disclaiming the 'enticing words of man's wisdom,' he could, when the occasion required it, use the arts and display the accomplishments of the rhetorician. His speeches in the *Acts of the Apostles* are worthy of the Roman senate; and his answers, when at the bar, to the questions proposed to him by the court, are distinguished for their address and their dignity. At the same time, wherever he happened to be, whether among the Jews in Pisidia, or the Gentiles at Lystra, or the polished Greeks at Athens, or pleading before Felix and Agrippa, his discources are adapted with admirable judgment and ability to the character and capacities of his several audiences. On the subject of St. Paul's writings, see Dr. Harwood, Michaelis, and Bishop Newton.

There is a tradition in the church that Paul was beheaded near Rome, and buried about two miles from the city, in the Via Ostiensis. A magnificent cathedral dedicated to his memory was built over his grave by Constantine. 'But his noblest monument,' observes Dr. Hales, 'consists in his immortal writings, which, the more they are studied, and the better they are understood, the more they will be admired to the latest posterity for the most sublime and beautiful, the most pathetic and impressive, the most learned and profound specimens of Christian piety, oratory, and philosophy.'

PAUL, ST., CATHEDRAL OF. [London.]

PAUL OF SAMO'SATA was chosen bishop of Antioch in A.D. 260. In consequence of being supposed to hold heterodox opinions concerning the person of Christ, a synod was assembled at Antioch about A.D. 264, to inquire into his sentiments. After holding several meetings, this synod was unable to extract from Paul an avowal of his suspected heresies. In the year 269 another synod was convened on this business, consisting of a large number of bishops, at which Malchion, a rhetorician and presbyter of the church at Antioch, succeeded in convicting Paul of the erroneous opinions imputed to him. He was excommunicated by this synod, which wrote an epistle to Dionysius, bishop of Rome, and to the churches of the empire, giving the reasons for their decision. Fragments of this epistle have been preserved by Eusebius. Though deprived of his bishopric, Paul refused (probably under the protection of Zenobia, who is known to have favoured him) to give up 'the house of the church' till the year 272 or 273, when the bishops who had excommunicated him applied to the emperor Aurelian, who compelled Paul to yield. It is probable that he continued after this to propagate his doctrines. His followers formed a sect under the name of Paulians or Paulianists, which seems to have lasted to the fifth century. They were condemned by the Council of Nice, who ordered those baptised among them to be re-baptised.

The accounts we have of his doctrines are not very clear. The synodical epistle of the council which deposed him speaks less of them than of his personal character, which is represented as marked by pride and arrogance, haughtiness in the exercise of his authority, and great love of pomp and display. He held some secular office together with his bishopric.

The following statement of his opinions by Mosheim appears, as far as we have the means of judging, to be tolerably correct:—'That the Son and the Holy Ghost exist in God, in the same manner as the faculties of reason and activity do in man; that Christ was born a mere man; but that the reason or wisdom of the Father descended into him, and by him wrought miracles upon earth, and instructed the nations; and, finally, that on account of this union of the divine Word with the man Jesus, Christ might, though improperly, be called God.'

(Lardner's *Credibility*, pt. ii., chap. xliii., sect. 8; Mosheim's *Ecclesiastical History*, Cent. iii., pt. ii., chap. v., sect. 15.)

PAUL THE DEACON, or PAULUS DIA'CONUS, called also Warnefridus from his father's name, was born about the year 740, at the town of Friuli (Forum Julii). He same attached to the court of Rachis, king of the Lombards, and afterwards (about 763) he left the court and was ordained deacon of the church at Aquileia. He returned to the court on the invitation of Desiderius, successor of Rachis, by whom he was made chancellor. About the part of his life which followed the overthrow of the kingdom of Desiderius by Charlemagne in 774, we know nothing for certain; but the most probable account is, that he retired to a monastery, and afterwards entered the celebrated monastery of Monte Casino, whence he addressed to Charlemagne, in the year 781, an elegy, in which he implores the release of a brother who had been taken prisoner in the Lombard war. About this time Charlemagne appears to have attached him to his court. He was employed to instruct in Greek the clergymen who were to accompany the emperor's daughter Rotrude in her journey to Constantinople to be married to the son of the empress Irene. Paul visited France, and stayed some time at Metz, of the early bishops of which city he wrote a history. He afterwards returned to Monte Casino, where he died about the year 799.

As a poet Paul is spoken of in the most extravagant terms of praise by his contemporary Peter of Pisa. His poems, which are really good, consist chiefly of hymns and other short pieces in Latin. His fame rests however chiefly on his merits as an historian. His works were,—1, 'Historia Miscella,' a Roman history consisting of twenty-four books, of which the first eleven contain the history of Eutropius; the next five, by Paul himself, contain the period from the reign of Valentinian to that of Justinian; the remaining books are attributed to Landulphus Sagax. The best edition of this work is in Muratori's *Rerum Italicarum Scriptores*. 2, 'De Gestis Longobardarum Libri Sex.' a history of the Lombards; his most valuable work. This also is contained in Muratori's collection. 3, 'Gesta Episcoporum Metensium.' 4, 'Life of St. Gregory the Great.' 5, 'Excerpta' from Festus *De Verborum Significatione*. [Festus.] There are also extant a collection of Homilies and two Sermons which are attributed to him.

(Muratori, *Rerum Ital. Script.*; *Biographie Universelle.*)

PAUL THE SILENTIARY, the son of Cyrus and grandson of Florus, was of a noble family and possessed of great wealth. He held in the palace of Justinian the office of chief of the Silentiarii, a class of persons who had the care of the emperor's palace. When the church of St. Sophia at Constantinople was rebuilt by Justinian (in 562). Paul wrote a description (or ἐκφρασις) of the edifice, in 1026 Greek hexameters, with a procemium consisting of 134 iambic verses. It is evident from this poem that he was a Christian. This work was edited, with notes and a Latin translation, by Du Cange, Paris, 1670. Paul was also the author of a poem entitled εἰς τὰ ἐν Πυθίοις θερμὰ, and of several Epigrams, which are included in the Greek Anthology.

(Fabricii *Bibliotheca Græca*, ed. Harles, vol. iv., p. 457; and vii., p. 581.)

PAUL I. succeeded Stephen III. in the see of Rome A.D. 757. He was involved in disputes with the Longobard king Desiderius, and sought the protection of Pepin, king of the Franks. He died in the year 768.

PAUL II., a Venetian by birth, succeeded Pius II. in 1464. He began by correcting abuses, and checking the exactions of the officers and secretaries of the Papal court, who levied contributions at pleasure from those who had occasion to apply to Rome for licences, rescripts, and other official papers. He endeavoured also to form a league of the Christian princes against the Turks, who threatened Italy, and for this purpose he proclaimed, in 1468, a general peace among the Italian governments, threatening with excommunication those who did not observe it. Paul, in 1471, gave to Borso of Este the investiture of Ferrara with the title of duke as a feudatory of the see of Rome. [Este, House of.] An academy had been formed at Rome for the cultivation of Greek and Roman antiquities and philology, of which Pomponius Lætus, Platina, and other learned men were members. Paul, who, unlike his predecessor Pius II., had no taste for profane learning, became suspicious of the academicians and their meetings. Some one probably excited his suspicions, by accusing them of infidelity and of treasonable designs. The academy was proscribed, some of its members ran away, others were seized and tortured, and among them Platina, who after a year's imprisonment was released through the intercession of several cardinals. It may easily be supposed that Platina, in his 'Lives of the Popes,' which he wrote afterwards under

Sixtus IV., did not spare the memory of Paul II. But besides Platina, other contemporary writers, such as Corio, Ammirato, an anonymous chronicler of Bologna, and the monk Jacopo Filippo of Bergamo, all speak unfavourably of this pope. Paul II. died suddenly in July, 1471, and was succeeded by Sixtus IV. Cardinal Querini has undertaken the defence of Paul II., in his 'Vindiciae adversus Platinam aliosque Obtrectatores.'

PAUL III., Cardinal Alessandro Farnese, succeeded Clement VII., in October, 1534. At that time the most urgent applications were made by the various states of Europe to Rome for the assembling of a general council, which was required by the state of the Western church, distracted by the schism of Luther and Zwingli, as well as by that of Henry VIII. of England. Paul however took a long time to consider before he finally acceded to the request, and it was only in 1542 that he issued the bull of convocation. In the mean time he excommunicated Henry VIII., and released his subjects from their oath of allegiance, by which measure he hastened the total separation of England from Rome. In 1540 he sanctioned the new order of the Jesuits. The war between Francis I. and Charles V. occasioned a further delay in the assembling of the council, which was finally opened at Trent in 1545. That assembly, which was prorogued several times, transferred to Bologna, and afterwards removed again to Trent, did not terminate its sittings till 1563, long after Paul's death.

Paul was very anxious to aggrandize his own family. He had a natural son, Pier Luigi Farnese, whom he first made duke of Castro, and afterwards duke of Parma and Piacenza. For his grandson Ottavio Farnese he obtained the hand of Margaret, a natural daughter of Charles V., and made him duke of Camerino. The pope subdued the people of Perugia, who had revolted against him, put to death several of the leaders, and built a citadel to keep the citizens in awe. He also attacked the Colonna, the most powerful baronial family in the neighbourhood of Rome, took all their strong holds, and obliged the members of that family to take refuge in the fiefs which they held in the kingdom of Naples. He sent a contingent of 12,000 foot and about 1000 horse, under his grandson Duke Ottavio, to join the emperor's army in Germany against the Protestant princes, and he afterwards strongly opposed the religious pacification granted by Charles, in 1547, under the name of the 'Interim.' In the same year Paul received the news of the tragical death of his son Pier Luigi, who was murdered at Piacenza, where he had made himself odious by his tyranny and his lust. Overcome by grief at the news, he told his two grandsons, Ottavio and Cardinal Farnese, who were with him at the time, to take warning from their father's death, and to live in the fear of God. Having secured the succession of Parma and Piacenza to Pier Luigi's son, Paul died, in November, 1549, at a very advanced age, and was succeeded by Julius III.

PAUL IV., Cardinal Gianpietro Caraffa, who was of a noble Neapolitan family, succeeded Marcellus II. in 1555. He was old, haughty, intolerant, and intent upon aggrandizing his nephews. He quarrelled with Philip II. of Spain, who sent the duke of Alba with an army from Naples to invade the papal territory. The duke advanced to the gates of Rome, but after some demonstrations a peace was concluded in 1557. Having learned that his nephews, one of whom he had made a cardinal, were leading a most dissolute life, and were plundering both the people and the treasury of the church, he banished them from Rome in 1559. Paul IV. died shortly after, eighty-four years of age. He had been a zealous advocate of the tribunal of the Inquisition. As soon as the news of his death became known, the people of Rome rose in insurrection, ran to the prison of the Inquisition, wounded a Dominican monk who acted as commissary, delivered all the prisoners, and burnt the papers. They then threw down the statue of the pope, crying out 'Death to the Caraffas.' The tumult lasted several days, after which the conclave elected a new pope by the name of Pius IV., who instituted a process against the nephews of the late pope, two of whom, Cardinal Caraffa and the duke of Paliano, were found guilty of several crimes, and put to death in 1560.

[Botta, *Storia d' Italia*, b. 10; Caracciolo, *Collectanea historica de Vita Pauli IV.*]

PAUL V., Cardinal Camillo Borghese of Rome, succeeded Leo XI. in 1605, when he was fifty-three years of age. His first act was a dispute with the senate of Venice concerning two ecclesiastics, subjects of that state, who, having been accused of heinous crimes, were on their trial before the civil magistrate. The pope asserted that clerical men could only be tried by their bishops, and as the Venetian senate maintained their rights, Paul laid Venice under interdict. The senate forbade the publication of the bull, and as the members of several monastic orders professed that they could not continue to perform religious worship in a country placed under interdict, they were allowed to quit Venice, and the senate appointed secular priests to perform service in their stead. The people remained perfectly quiet, and the bishops and vicars continued their functions as usual. It is reported that the grand-vicar of the bishop of Padua having said to the podestà, or civil governor of that city, that he ought to act conformably to the inspiration of the Holy Ghost, the podestà replied to him that he understood that the Holy Ghost had already inspired the Council of Ten with the resolution of hanging all those who would not obey the orders of the senate. (Botta, b. 15.) Paolo Sarpi, the senator Antonio Querini, and others, wrote in defence of the senate, and Cardinal Baronius and Bellarmine wrote in defence of Rome. There were three points at issue between the pope and the senate: 1, the senate had made a decree that no new convent or religious congregation should be founded without their permission; 2, that no property or perpetual revenue of any kind should be bequeathed to the church without their approbation; 3, that clerical men accused of crimes should be judged by the secular power like other citizens. The king of France and the emperor took the part of Venice, the court of Spain that of the Pope, and Italy was threatened with a war like that of the Investitures. Henri IV. of France however proposed his mediation, and sent to Venice Cardinal de Joyeuse, who, after consulting with the senate, proceeded to Rome, where he succeeded in effecting a compromise. The decrees of the senate were maintained, but the two clerical culprits, in compliance with the wish of the French king, were given up to the pope, 'saving the right of the republic to punish all offenders, clerical or lay, within its dominions.' Upon this arrangement being made, the interdict was removed.

In 1614 Pope Paul had a dispute with Louis XIII., on account of a book of the Jesuit Suarez, entitled 'Defensio Fidei,' in which the author maintained that in certain cases it was lawful to murder kings. This book was publicly burned by sentence of the parliament of Paris. The pope maintained that he was the proper authority to decide upon the contents of works concerning religious and moral doctrines, and that the book ought to have been referred to him. This affair was likewise settled by a compromise.

The pope was in the meantime usefully employed in reforming many abuses in the tribunals and other offices of the Roman court, and in embellishing the city of Rome. In this respect he ranks among the most distinguished pontiffs for his encouragement of the fine arts. He enlarged the Vatican and Quirinal palaces, restored the church of Santa Maria Maggiore, constructed or repaired aqueducts, made additions to the Vatican library, collected statues and other antiquities, and built the handsome villa Mondragone at Frascati. He established the fortune of the Borghese family, which is one of the wealthiest of the Roman families. Paul V. died in 1621, and was succeeded by Gregory XV.

PAUL I., emperor of Russia, son of Peter III. and Catherine II., was born in 1754. He lost his father at an early age, and the death of his brother Ivan, in 1763, made him heir apparent to the crown. He had good instructors, but was treated with great strictness by his mother as long as she lived, and was studiously kept in ignorance of all public affairs. She often expressed an unfavourable opinion of his judgment and disposition, and it is believed that she would have disinherited him had she been able to do it. In 1776 Paul married Mary of Würtemberg, an amiable princess, by whom he had four sons, Alexander, Constantine, Nicholas, and Michael, and several daughters. In 1780 he travelled with his wife through Germany, France, and Italy, under the title of 'Comte du Nord.' On his return to Russia he continued to live in retirement, at the country residence of Gatschina, thirty miles from Petersburg, and his sons and daughters were educated at court, under the eye of the empress. In 1796, on the death of Catherine, Paul, then 42 years of age, emerged from his restraint, and was proclaimed emperor. He began by causing solemn funeral honours to be paid to his father, together with the late empress, and for this purpose he had the coffin containing his body removed from the place where it had been deposited, and placed in the church by the side of the corpse of Catherine. Paul also went in person to release the Polish patriot Kosciuzko, who was confined as a state prisoner, not however in a dungeon, as some have said, but in a private house, under a military guard, and he gave him money to enable him to go and live in the United States. He likewise liberated Pototsky and the other unfortunate Poles who were confined at Schlusselburg and other fortresses. These acts of the new emperor gave hopes of a good reign, but Paul's character soon showed itself in all its capriciousness and violence. He liked to interfere in the most minute details of police and of military discipline; he forbade the wearing of round hats in the streets of Petersburg; he likewise proscribed trowsers and frock coats, and several foreigners were ill-used in consequence of these absurd regulations. Any one who met him in the street was obliged to take off his hat, even in the severest weather, and ladies were required to alight from their carriages. For the former convenient dress of the Russian infantry, consisting of a jacket and pantaloons, he substituted the German uniform, with tailed coats, spatterdashes, and queues bedaubed with grease and flour as being cheaper than powder and pomatum. This caused much discontent among the soldiers and numerous desertions, a thing almost unknown till then in the Russian army. In the same spirit, Paul, whose only wish was to alter rather than to improve, remodelled all the departments of administration, and all the courts of the empire, in consequence of which thousands of civil officers were thrown out of employment.

In his foreign politics Paul at first seemed disposed to adopt a system of neutrality in the great quarrel between France and the allied powers. But he soon became alarmed at the progress of the French arms, and at the encroachments of the French directory; the invasion of Switzerland, of Rome, Naples, Malta, and Egypt, determined him for war. He had an army of from 40,000 to 50,000 men assembled in Gallicia by Catherine, and he ordered it to join the Austrians and march upon Italy. The veteran Suwarrow, the most distinguished general of Russia, who had been dismissed by Paul soon after his accession, for having sneered at his martinet innovations in the army, was appointed to command the expedition. For an account of his successful campaign in Italy, in 1799, see SUWARROW. Another Russian army, 40,000 strong, under General Korsakow, was sent to join the Archduke Charles in Switzerland. This army was defeated by Massena, at Zürich, in September, 1799. A third army was sent to join the English, under the Duke of York, in Holland, and that expedition also failed. A fourth Russian army was embarked in a fleet, which, joined to the Turkish fleet, conquered the Ionian Islands, and assisted in restoring the king of Naples to his continental dominions. In the end however, Paul was sorely disappointed in his military expectations. His best general, Suwarrow, after the conquest of Italy, having marched into Switzerland to join his comrades there, arrived just after the defeat of Korsakow, and was obliged to retreat through the Alps of Glaris into the Grisons country. He and his army were recalled by the emperor, and Suwarrow arrived, desponding and in bad health, at Petersburg, where he soon after died. Paul, who had broken the heart of the veteran by attributing to him the disasters in Switzerland, in which he had had no part, relented towards him in his last moments, sent to inquire how he did, and allowed the grand-dukes, his sons, to go and visit him. Paul withdrew from the coalition without publishing his reason for it; he offended the allies, but at the same time made no proposals of peace to France. He thus displeased everybody, and showed himself fickle, passionate, and weak. His private conduct partook of the same character. He became more stern and morose, showed suspicion of everybody, and was disliked by all. The soldiers detested him for his vexatious minuteness in discipline, the nobility for his rude and often cruel behaviour, and men of information for his proscription of books and journals. Paul chose to quarrel with England because she would not give up Malta. He had caused himself to be elected grand-master of the order of St. John, after the death of the grand-master Hompesch, and he expected England to give up the island to him. After the battle of Marengo, Bonaparte bethought himself of profiting by this disposition of Paul, in order to gain his friendship. He accordingly collected all the Russian prisoners in France, clothed them, supplied them with muskets, and sent them back to Russia. This produced its effect, and Paul, who had proclaimed himself the champion of legitimacy, became all on a sudden a great admirer of Bonaparte.

His next step was to seize the English vessels and other property in his harbours, because England had sent a fleet to Copenhagen in August, 1800, to oblige Denmark to acknowledge the navigation laws and the right of search of neutral vessels. In December of the same year, Paul concluded a convention with Sweden and Denmark, to which Prussia soon after acceded, by which the right of search of neutral vessels was declared an attempt against the sovereign rights of the nation to which they belonged, and a squadron of the four Baltic powers was to be assembled to protect their merchant vessels, and resist any attempt at searching them. In consequence of this step England put an embargo upon the vessels of the Baltic powers. Paul now sent an agent to Bonaparte, and friendly communications were re-established between France and Russia. Bonaparte even accepted Paul's mediation in favour of the court of Naples, which was still at war with France. Count Kalitscheff came to Paris as ambassador of Russia, and was received with great distinction. 'France,' said Bonaparte publicly, 'can ally itself only with Russia, for Russia is mistress of the Baltic and Black seas, and she holds the keys of India in her hands, and the emperor of such a country is truly a great prince. Paul is eccentric, but he has at least a will of his own.' (Thibaudeau, *Le Consulat et l'Empire*, ch. xiv.)

After peace was concluded at Luneville between France and Austria, in February, 1801, Bonaparte secretly concerted with the court of Russia the plan of an expedition to India. Thirty thousand chosen French troops were to march into Poland, and there join an equal number of Russian infantry, besides 40,000 Cossacks and other irregular cavalry, and thence the allied army was to proceed to the borders of the Caspian Sea, either to embark and cross that sea or march by the way of Persia, whose consent was solicited by the two powers. (Thibaudeau, ch. xv.) Meantime England had sent a fleet into the Baltic, under admirals Parker and Nelson, to dissolve the maritime coalition. On the 2nd of April, Nelson attacked the Danish fleet, and on the 4th an armistice was signed between Denmark and England. While the armistice was being concluded, news arrived of the sudden death of Paul, which happened in the night of the 24th of March. The Baltic coalition was thereby dissolved. A conspiracy had been formed among the officers near the person of the emperor, who went in a body at night to his apartments, and presented him an act of abdication to sign, on the score of mental weakness. Paul refused, saying 'he was emperor, and would remain emperor.' A scuffle ensued, in which the unfortunate monarch was overpowered and strangled. His son Alexander was proclaimed emperor.

When the news arrived at Paris, Bonaparte was greatly vexed and mortified. Talleyrand, to calm him, observed that 'this was the customary mode of abdication in Russia.' According to the practice of those times, the French papers intimated that England was privy to the conspiracy; but the fact is that the Russians had become weary of Paul's caprices, which bordered upon insanity, and the plan of forcing him to abdicate, though not of murdering him, appears for some time previous to have been discussed among the members of the court, and even of the Imperial family, as a measure of absolute necessity. At the news of his death, the whole city of Petersburg, the army, nobles, and people rejoiced.

PAUL, FATHER, the celebrated historian of the Council of Trent, whose original name, before he embraced the monastic profession, was Pietro Sarpi, was born at Venice, in the year 1552, of a respectable commercial family. His father however was unsuccessful in trade; and his mother, a woman of sense and virtue, was early left a widow in indigent circumstances. Fortunately her brother was the master of an excellent school, and under his care she placed her son, who from infancy displayed an extraordinary aptitude for study. Before the completion of his fourteenth year, he had made great progress in mathematics and logic, as well as in general literature; and at that boyish age, having become a pupil of the logician Capella of Cremona, ho was of the Servite order, this connexion led him, con- rary to the urgent advice of his uncle and mother, to adopt he same monastic habit and rule with his preceptor. In is twentieth year he solemnly took the vows of the order.

At the same period, the ability which he displayed in a ublic disputation, held at Mantua, during a chapter of his rder, attracted the favourable notice of the reigning prince f the house of Gonzaga, and he was appointed to the pro- essorship of divinity in the cathedral of that city. But ough he was honoured with many marks of regard by the antuan duke, a public life was little to his taste; and he oon resigned his office and returned to the learned se- lusion which he loved. In that retirement he continued to ultivate learning and science; and in his twenty-second ear, he had not only already mastered the Latin, Greek, ebrew, and Chaldee languages, but was also a proficient n the civil and the canon law, in various departments of hilosophy, in mathematics and astronomy, in chemistry, edicine, and anatomy. In these last sciences he became eeply versed for his times, and it has been alleged that he as acquainted with the circulation of the blood.

The claim of Sarpi to be considered the discoverer of the rculation rests on the authority of Veslingius, who states, his 'Epist. Anat. et Medicæ,' ep. xxvi., that he had read manuscript by Sarpi, belonging to his pupil and successor ulgentius, in which the circulation was described. George nt (Harvey's commentator and friend) admitted the tes- mony, but said that whatever Sarpi knew of the circula- on, he learned from Harvey himself. Riolanus, Harvey's our adversary, gives no credit for the discovery to Sarpi; nd Fulgentius himself does not claim it for him.

Several writers attribute to Sarpi the discovery of the alves of the veins, which gave Harvey the first idea of a rculation; but Fabricius was acquainted with them in 574, when Sarpi was but 22 years old, and it is certain at he (Fabricius) taught Harvey their existence.

The above is on the authority of Haller (*Bibliotheca Ana- omica*), who does not attribute any part of the discovery to arpi.

The pursuit of such studies, and the renown which they ocured for him, no less than the freedom of his expressed inions in correspondence with the kindred minds of his e, drew upon him the envy and suspicion of the mean and gorant; and he was twice arraigned before the Inquisition a false and absurd accusation of heresy, and on a better- unded charge of having declared in a letter his detestation the papal court and its corruptions. His high reputation aved him in both cases; but the court of Rome never rgave him, and, at a subsequent period, revenged and jus- fied his bad opinion of its administration by refusing to ward his unquestionable merits with preferment to a bi- opric. The famous dispute which arose between the Ro- an see and the republic of Venice, during the pontificate Paul V., in the year 1606, drew the speculative recluse om the quietude which had only been thus partially in- rrupted, into open and dangerous collision with the papal wer. When Paul V. endeavoured to revive the doctrines the supremacy of the popedom over all temporal princes d governments, and reduced these pretensions to practice laying the Venetian state under an interdict and excom- unication for having subjected priests to secular jurisdic- on, the senate of Venice, not contented with setting these ritual weapons at defiance, determined to support by argu- ent the justice of their cause. The most eloquent and ccessful advocate whom they employed for this purpose s Father Paul; and animated both by zeal in the service his native state and by indignant opposition to the omish usurpations, he fulfilled his task with equal courage d ability. Though several cardinals and Jesuits strenuously gaged in the controversy on the papal side, the fallacy of e pretensions which they attempted to uphold was so sig- lly exposed by Sarpi and others, that the pope, finding his apons contemned, his efforts unsupported by his political ies, and his sentence rendered nugatory by the firmness the Venetian senate, was finally compelled to consent to accommodation very honourable to their state.

The papal party however, though reduced to yield to the ower of that republic and the strength of her cause, was olved not to forego its vengeance against her defenders, nd among them Father Paul was signally marked for a ctim. Several attempts were made to assassinate him; notwithstanding the apparent security of his retreat at Venice, was attacked one night as he was returning home to his monastery by a band of ruffians, who inflicted on him no fewer than twenty-three wounds. The assassins escaped in a ten-oared boat; and the papal nuncio and the Jesuits were naturally suspected of being the authors of a plot prepared with such a command of means and expensive precautions. None of the wounds of Father Paul were mortal; and preserving one of the stilettos which the assassins had left in his body, he surmounted it with the appropriate inscription, 'Stilo della chiesa Romana' ('Pen (or dagger) of the Romish church').

These attempts upon his life compelled Father Paul to confine himself to his monastery, and induced him to employ his constrained leisure by engaging in the great literary composition by which he is chiefly remembered, 'The History of the Council of Trent;' a work which has been not more deservedly commended for its style as a model of historical composition, than for the extent of its learning, the generous candour of its spirit, the unbiassed integrity of its principles, and the unostentatious piety of its sentiments. While occupied in this and other labours of minor import, Father Paul was overtaken by death, in his seventieth year. A neglected cold produced a fever, the immediate cause of his dissolution; and after lying for nearly twelve months on a bed of sickness, which was supported with the usual edifying cheerfulness and piety, he expired in the beginning of the year 1623, and his memory was honoured by the gratitude of the Venetian republic with a public funeral.

The discussion of Father Paul's theological opinions and conduct is beyond our province. His opposition to the papal see has drawn upon his character the severe animadversions of Roman Catholic divines, and procured for it in a consequent degree the favour of Protestant writers. It may here suffice to observe that the uprightness of his motives and the sincerity of his religious faith have never fairly been impugned; while his leaning to the doctrines of the Protestant churches has been variously inferred as a matter either of commendation or reproach. The reader will find various notices on this subject scattered through the Dictionary of Bayle; though it is to be regretted that Bayle, after promising in the early part of his work to devote an article expressly to the personal and literary history of Sarpi, was prevented by his limits from fulfilling a design so congenial to his tastes. A Life of Father Paul however was published in England in 1651, and also at Leyden in 1661; and an able and accurate sketch of his fortunes and character is to be found in our language among the collected works of Dr. Samuel Johnson. Editions of Father Paul's 'History of the Council of Trent' were published in London, in Italian, English, and French, in 1619, 1676, and 1736; and of his whole works, in the original language, at Verona and Naples, in 1761-68, and 1790.

PAUL VERONE'SE. [CAGLIARI.]

PAULICIANS. [MANICHEANS.]

PAULI'NUS, SAINT PO'NTIUS MERO'PIUS, bishop of Nola, was born about A.D. 353, at Bordeaux, of a noble family. He was a pupil of Ausonius, and was recommended by him to the emperor Gratian, who appointed him consul in 378, and afterwards advanced him to several offices of great importance. Through the influence and exhortations of St. Ambrose, he was induced to relinquish the world and give his property to the church. He was ordained presbyter in 393, was made bishop of Nola in 409, and died in 431.

Paulinus wrote several works, of which only a few have come down to us; the principal of which are a discourse on alms-giving, some letters, and a few poems on religious subjects. Paulinus was intimate with the most distinguished theologians of his time, and is frequently mentioned in the Epistles of St. Augustin and St. Jerome. His works were published for the first time by Badius, Paris, 1516; but the best editions are by Muratori, Verona, 1736, fol.; and the one printed at Paris in 1685, 2 vols. 4to.

PAULI'NUS, SAINT, patriarch of Aquileia, is chiefly known in ecclesiastical history for the exertions he made in defence of the Trinity. He was born near Friuli, about 730, and was made patriarch of Aquileia by Charlemagne in 776. He died in 804. His works have been published by Madrisi, Venice, 1737.

PAULINUS, better known under the name of **JOHN PHILIP WERDIN,** was born near Mannersdorf in Austria, on the 25th of April, 1748. He studied philosophy and theology at Prague, and afterwards learned some of the oriental languages in the college of the Carmelites at Rome, which order he had joined in 1769. He was sent to the coast of Malabar in 1774, where he remained for 14 years, and was successively appointed vicar-general and apostolic visitor. In 1790 he returned to Rome in order to superintend the religious works which were printed by the Propaganda for the use of the missionaries in Hindustan. He died at Rome, on the 7th of January, 1806.

Paulinus was one of the earliest Europeans who acquired a knowledge of the Sanscrit language. In consequence of his being settled in the south of Hindustan, he was not placed in such favourable circumstances as our countrymen in Bengal for obtaining an accurate knowledge of Sanscrit, since the Brahmans of the north are much more skilled in that language than those of the south. Paulinus however was very unwilling to admit his inferiority to the English scholars, and he frequently attacked them in his works. The Sanscrit Grammar of Paulinus is published in the Tamul character instead of the Devanagari, which is the character in which all Sanscrit works are written in the north of Hindustan, and which is employed in the Sanscrit grammars and works which have been published at Calcutta and in Europe.

The Sanscrit Grammar of Paulinus was published at Rome, in 1790, under the title of 'Sidharubam, seu Grammatica Samscrdamica, cum Dissertatione historico-critica in Linguam Samscrdamicam,' and also in a fuller and different form in 1804, under the title of 'Vyacarana, seu locupletissima Samscrdamicæ Linguæ Institutio;' but both these works are entirely superseded by the more accurate and complete grammars of Wilkins and Bopp. Paulinus also wrote and edited many other works, of which the most important are:—'Systema Brahmanicum liturgicum, mythologicum, civile, ex monumentis Indicis, &c., dissertationibus historicis illustravit,' Rom., 1791; 'India Orientalis Christiana, continens Fundationes Ecclesiarum, Seriem Episcoporum, Missiones, Schismata, Persecutiones, Viros illustres,' Rom., 1794; 'Viaggio alle Indie Orientali,' Rom., 1796; 'Amarashinha, seu Dictionarii Samscrdamici sectio prima, de Cœlo; ex tribus ineditis Codicibus Indicis Manuscriptis, cum Versione Latina,' Rom., 1798 (the whole of this dictionary, of which Paulinus has edited the first part, was printed at Serampore, in 1808, under the care of Colebrooke); 'De Antiquitate et Affinitate Linguæ Zendicæ et Samscrdamicæ germanicæ Dissertatio,' Rom., 1798, Padua, 1799; and 'De Latini Sermonis Origine et cum Orientalibus Linguis Connexione,' Rom., 1802.

PAULINUS SUETO'NIUS. [BOADICEA; BRITANNIA.]

PAULO, S. [PAOLO, S.]

PAULUS ÆGINE'TA (Παῦλος Αἰγινήτης), so called from his birthplace, the island of Ægina, in the Sinus Saronicus, is one of the latest and at the same time one of the most valuable of the antient Greek medical writers whose works are still extant. Abulfaraj (*Hist. Dynast.*, p. 114, ed. Pococke) states that he lived in the seventh century A.D., which is probably somewhere near the truth, as he quotes Alexander Trallianus (lib. iii., cap. 28; vii. 5, 11, 19), who is supposed to have lived about the middle of the sixth. Nothing is known of the events of his life, except that he travelled a great deal, as we learn from the two following barbarous Greek iambics prefixed to his work:—

Παύλου πόνον με γνῶθι τοῦ γῆς τὸ πλέον
διαδραμόντος, φύντος ἐκ γῆς Αἰγίνης.

It is on this account (as some think) that he is sometimes called *περιοδευτής*, but according to others, the epithet signifies 'qui obeundis ægrotorum decumbentium ædibus medicinam facit.' He appears to have visited Alexandria (lib. vii., cap. 17; and iv. 49); and it is probable that he there obtained the title *ἰατροσοφιστής*, which is sometimes given him. Suidas says he wrote various medical works (*ἰατρικὰ βιβλία διάφορα*); and Abulfaraj, that he composed a treatise on medicine, in nine books, and one on female diseases. The latter work (if some parts of the first, third, and sixth books, which treat of that subject, are not meant) is lost; the former still remains, with the title *ἐπιτομῆς ἰατρικῆς βιβλία ἑπτά*, 'Compendii Medici Libri Septem.' As there is no reason for supposing this work to be imperfect, it is probable that each of the third and seventh books, which are much longer than the rest, was divided by the Arabic translator into two. He appears to have been much esteemed by the Arabians, who, on account of his skill in midwifery and female diseases, called him *Al-Kawabeli*, 'the accoucheur.' His remaining work is chiefly a compilation from Galen, Oribasius, Aëtius, and others; and indeed he tells us himself in the preface, that he meant it to supersede the short abridgment, by Oribasius, of his own larger work, the 'Hebdomecontabiblon;' however it contains also a good deal of original matter, though the author speaks very modestly of his own additions. The following account of the contents of each book is given by himself in his preface, and the English translation by Mr. Adams has been adopted. 'In the first book you will find everything that relates to Hygiene, and to the preservation from and correction of distempers peculiar to the various ages, seasons, temperaments, and so forth; also the powers and uses of the different articles of food, as we have explained in a summary manner. In the second is explained the whole doctrine of fevers, an account of certain matters relating to them being premised, such as excrementitious discharges, critical days, and other appearances, and concluding with certain symptoms, which are sometimes the consequences of fever. The third book relates to topical affections, beginning from the crown of the head, and descending down to the nails of the feet. The fourth book treats of those complaints which are external and exposed to view, and are not limited to one part of the body: also of intestinal worms and dracunculi. The fifth treats of the wounds and bites of venomous animals; also of the distemper called hydrophobia, and of persons bitten by dogs which are mad, and by those which are not mad; and also of persons bitten by men: among other things it treats of deleterious substances and the preservatives from them. In the sixth is contained everything relating to surgery, both what relates to the fleshy parts, such as the extraction of weapons; and to the bones, which comprehends fractures and dislocations. In the seventh is contained a description of the properties of all medicines, first of the simple, then of the compound; particularly of those which I have mentioned in the preceding six books, and more especially the greater, and, as it were, celebrated preparations. Towards the end are certain things connected with the composition of medicines, and of those articles which may be substituted for one another; the whole concluding with an account of weights and measures.'

The most valuable and original part of his work is the sixth book, which contains several descriptions of operations, either first mentioned there, or else with more accurate and precise directions than in any former author. There is a minute and excellent account of bronchotomy, taken from Antyllus (vi. 33). He recommends the jugular veins to be opened (vi. 40), and also in some cases the division of an artery (*ibid.*). He describes minutely and accurately the different kinds of hernia, and the operation necessary for replacing the intestine (vi. 65). He notices that few persons, if any, recover if hydrophobia comes on after the bite of a mad dog; but that if the wounded part be immediately cut out, there is but little danger (v. 3). He gives directions for opening an imperforate hymen (vi. 72) and anus (vi. 81). The work is also valuable as containing fragments of many authors whose writings are lost, such as Antyllus, Archigenes, and Diocles Carystius; the letter sent by the last writer to king Antigonus, entitled προφυλακτική, 'Ad Valetudinem Tuendam,' is inserted at the end of the first book.

The Greek text was first published, Venet., 1528, fol., in ædib. Aldi et Andr. Asulani; the second and last edition, which is much superior to the former, was published Basil., 1538, fol., ap. Andr. Cratandrum, under the care of Hier. Gemusæus. There are three Latin translations of the whole work, besides several others of detached parts —1, That by Albanus Torinus, Basil., 1532, fol., and several times reprinted, together with the sixth book, which was omitted in the first edition; 2, That by Jo. Guinterius Andernacus, Paris, 1532, fol., much superior to the former, and several times reprinted; and 3, That by Ja. Cornarius, Basil., 1556, fol., accompanied by a valuable commentary, or (as he expresses it) '*dolabellarum*, sive castigationum in libris septem *dedolata* ac lævigata.' This translation and commentary are inserted in the 'Medicæ Artis Principes,' Paris, 1567, fol., ap. Henr. Steph. An Arabic translation was made by the celebrated Honain Ibn Ishak, better known perhaps by his Latinised name *Joannitius* (*Hist. Philosoph.*, apud Casiri, *Biblioth. Arabico-Hisp. Escur.* tom. i., p. 288), which, according to Haller (*Biblioth. Chirurg.*), still exists somewhere in MS. There is an

English translation with a copious and learned commentary, by Francis Adams, of which unhappily only the first volume is published, Lond., 1824, 8vo.

PAULUS, JULIUS, one of the most distinguished of the Roman lawyers, was the contemporary of Ulpian, and may be most conveniently referred to the time of the emperor Alexander Severus. The place of his birth is unknown. The reasons alleged for supposing him to be a native of Syria, namely, his intimacy with Ulpian, who was a native of Tyre, and with Mammaea, the mother of Alexander Severus, who was a native of Emesa, are manifestly no proofs at all. In addition to this, there is the negative evidence derivable from his own silence on an occasion when he might have said that he was a native of Syria, if such was the fact (*Dig.*, 50, tit. 15, s. 1, 10). It has also been supposed that he was a native of Padua, an opinion founded on the fact of there being at Padua a statue which bears the name of Paulus; and the inscription is obviously comparatively recent. But the statue and inscription may refer to another person. The Græcisms supposed to characterise his style, and his familiarity with the Greek language, have been adduced as arguments confirmatory of his alleged foreign origin.

Paulus was also a contemporary of Papinian [PAPINIAN], and apparently rather his rival, than his pupil, as some writers have supposed. He was made præfectus prætorio by Alexander Severus, or, according to others, by his predecessor, Elagabalus. He was banished by Elagabalus, but recalled by Alexander Severus (Aurel. Vict., c. 24); unless Victor has confounded Paulus with Ulpian. (Lamprid., *Alex.*, c. 26.)

Paulus was perhaps the most voluminous of all the Roman writers on law, and the extracts from his works contained in the 'Digest' are more numerous than those from any other writer except Ulpian. According to Haubold, the 'Digest' contains 2462 extracts from Ulpian, and 2083 from Paulus. The proportion which each body of extracts bears to the whole compilation is shown in the article JUSTINIAN'S LEGISLATION.

Paulus wrote under the emperor Antoninus Caracalla and his successors to the time of Alexander Severus. His style, so far as we can judge from the extracts in the 'Digest,' is concise, and sometimes obscure, owing to his leaving the reader to supply some of the steps in his argument. Like the rest of the great Roman jurists, he was subtle in thought and clear and comprehensive in his judgments. He has been accused of violent hatred of the Christians, but the accusation is not supported by proof.

The following are the titles of a few of the works of Paulus: 80 books on the 'Edict,' 26 books of 'Quæstiones,' 23 books of 'Responsa,' 23 books of 'Brevia,' 5 books of 'Sententiæ,' dedicated to his son, 3 books on 'Adultery,' &c. A complete list of the works of this laborious jurist is given by Zimmern (*Geschichte des Römischen Privatrechts*, &c.). Of all these works there only remain the excerpts in the 'Digest,' and the 5 books of the 'Receptæ Sententiæ,' which are preserved in an imperfect shape in the compilation made by the order of Alaric II., commonly called the 'Breviarium Alaricianum.'

A very full account of Paulus and his writings, by Ber-[illegible], is contained in the *Jurisprudentia Vetus Ante-Justinianea* of Schulting.

PAULUS ÆMILIUS. [ÆMILII.]

PAUMBEN. [HINDUSTAN, vol. xii., p. 205.]

PAUN-AIR. [HINDUSTAN, p. 208.]

PAUPERISM AND POOR LAWS. The term pauper, according to the most convenient use of the word, is a person receiving legal relief. It thus comprehends those who being without capital, but able and willing to labour, are unable to find permanent employment at rates of wages sufficient for their subsistence, and are wholly or partly supported by public funds. The term also comprehends orphan, bastard, and deserted children who require and receive legal relief; as well as those who, from age, sickness, or infirmity, are disabled from labour, have no means of support, and receive legal relief.

It must be evident from this definition that in every country those who are properly called paupers are only one class or division among several who are in the condition of poverty. The poor of a country, as distinguished from the paupers, may be distributed into three classes: 1. Persons without capital, who, being capable of labour, and finding employment, are able to obtain the means of subsistence. 2. Able-bodied mendicants, capable of labouring, who dislike work, and subsist by practising deceptions upon the humane and charitable. 3. Persons destitute through sickness, infirmity, desertion, or any other cause, and relieved by private charity.

The causes of pauperism are numerous, and it would be equivalent to an attempt to explain most of the phenomena of modern society, if we should affect to assign all its possible or even all its actual causes in any given country. Some of the causes however are clearly traceable to positive law. Every civilized community has necessarily a great body of laws which concern the rights of property, and which regulate to some extent the conduct of the individual members of a community. It is difficult even for a wise legislator to attempt to regulate a large community without doing some mischief by his interference; and the history of positive legislation in this and other countries shows that those who have had the power to make laws have not only ignorantly and unintentionally injured society by not perceiving the tendency of their own enactments, but have often purposely and designedly attempted to accomplish objects which they believed to be beneficial to society, but which an enlarged experience and a sound philosophy have proved to be detrimental to the general interest. When the object has been a good one, a legislator has often failed in accomplishing it, owing to ignorance of the proper means. In England legal interference with the condition of the poor has in some degree been exercised for nearly 500 years. In no country have greater efforts been made to regulate their condition, nor greater mistakes committed in this branch of government.

The great object of the earlier efforts in pauper legislation was the restraint of vagrancy. The 12th Richard II., c. 7 (1388), prohibits any labourer from quitting his dwelling-place without a testimonial from a justice of the peace, showing reasonable cause for his going, and without such a testimonial any such wanderer might be apprehended and put in the stocks. Impotent persons were to remain in the towns where they were dwelling at the passing of the act, provided the inhabitants would support them; otherwise they were to go to the places of their birth, to be there supported. By acts passed in the 11 and 19 of Henry VII. (1495 and 1504) impotent beggars were required to go to the hundred where they had last dwelt for three years, or where they were born, and were forbidden to beg elsewhere. By the act 22 Henry VIII., c. 12 (1531), justices were directed to assign to impotent poor persons a district within which they might beg, and beyond which they were forbidden to beg, under pain of being imprisoned and kept in the stocks on bread and water. Able-bodied beggars were to be whipped and forced to return to their place of birth, or where they had last lived for three years.

These acts appear to have had no permanent effect in repressing vagrancy. An act passed in 1536 (27 Henry VIII., c. 25) is the first by which voluntary charity was converted into compulsory payment. It enacts that the head officers of every parish to which the impotent or able-bodied poor may resort under the provisions of the act of 1531, shall receive and keep them, so that none shall be compelled to beg openly. The able-bodied were to be kept to constant labour, and every parish making default was to forfeit twenty shillings a month. The money required for the support of the poor was to be collected partly by the head officers of corporate towns and the churchwardens of parishes, and partly was to be derived from collections in the churches and on various occasions where the clergy had opportunities for exhorting the people to charity. Almsgiving beyond the town or parish was prohibited, on forfeiture of ten times the amount given. A 'sturdy beggar' was to be whipped the first time he was detected in begging; to have his right ear cropped for the second offence; and if again guilty of begging, was to be indicted 'for wandering, loitering, and idleness,' and if convicted was 'to suffer execution of death as a felon and an enemy of the commonwealth.' The severity of this act prevented its execution, and it was repealed by 1 Edward VI., c. 3 (1547). Under this statute every able-bodied person who should not apply himself to some honest labour, or offer to serve for even meat and drink, was to be taken for a vagabond, branded on the shoulder, and adjudged a slave for two years to any one who should demand him, to be fed on bread and water and refuse meat, and made to work by being beaten, chained, or otherwise treated. If he ran away during the two years, he was to be branded on the cheek, and adjudged a slave for life, and if he ran away again, he was to suffer death as a felon. If not demanded as a slave, he was to be kept to hard labour on the highways in chains. The impotent poor were to be passed to their place of birth or settlement, from the hands of one parish constable to those of another. This statute was repealed three years after, and that of 1531 was revived. In 1551 an act was passed directing that a book should be kept in every parish, containing the names of the householders and of the impotent poor; that collectors of alms should be appointed who should 'gently ask every man and woman what they of their charity will give weekly to the relief of the poor.' If any one able to give should refuse or discourage others from giving, the ministers and churchwardens were to exhort him, and, failing of success, the bishop was to admonish him on the subject. This act, and another made to enforce it, which was passed in 1555, were wholly ineffectual, and in 1563 it was re-enacted (5 Eliz., c. 3), with the addition that any person able to contribute and refusing should be cited by the bishop to appear at the next sessions before the justices, where, if he would not be persuaded to give, the justices were to tax him according to their discretion, and on his refusal he was to be committed to gaol until the sum taxed should be paid, with all arrears.

The next statute on the subject, which was passed in 1572 (14 Eliz., c. 5), shows how ineffectual the former statutes had been. It enacted that all rogues, vagabonds, and sturdy beggars, including in this description 'all persons whole and mighty in body, able to labour, not having land or master, nor using any lawful merchandise, craft, or mystery, and all common labourers, able in body, loitering and refusing to work for such reasonable wage as is commonly given,' should 'for the first offence be grievously whipped, and burned through the gristle of the right ear with a hot iron of the compass of an inch about;' for the second, should be deemed felons; and for the third, should suffer death as felons, without benefit of clergy. For the relief and sustentation of the aged and impotent poor, the justices of the peace within their several districts, were 'by their good discretion' to tax and assess all the inhabitants dwelling therein. Any one refusing to contribute was to be imprisoned until he should comply with the assessment. By the statutes 39 of Elizabeth, c. 3 and 4 (1598), every able-bodied person refusing to work for the ordinary wages was to be 'openly whipped until his body be bloody, and forthwith sent, from parish to parish, the most strait way to the parish where he was born, there to put himself to labour as a true subject ought to do.'

The next act on this subject, the 43 Elizabeth, c. 2, has been in operation from the time of its enactment, in 1601, to the present day. An entire change in the mode of administration which had grown up under its provisions, was however effected by the Poor Law Amendment Act (4 and 5 Wm. IV., c. 76), which was passed in 1839. During that long period many abuses crept into the administration of the laws relating to the poor, so that in practice their operation was subversive of the morals of the most numerous class, and injurious to the welfare of the whole country. In its original provisions the act of Elizabeth directed the overseers of the poor in every parish to 'take order for setting to work the children of all such parents as shall not be thought able to maintain their children,' as well as all such persons as, having no means to maintain them, use no ordinary trade to get their living by. For this purpose they were empowered 'to raise, weekly or otherwise, by taxation of every inhabitant, parson, vicar, and other, and of every occupier of lands, houses, tithes, mines, &c., such sums of money as they shall require for providing a sufficient stock of flax, hemp, wool, and other ware or stuff, to set the poor on work, and also competent sums for relief of lame, blind, old, and impotent persons, and for putting out children as apprentices.' Power was given to justices to send to the house of correction or common gaol all persons who would not work. The churchwardens and overseers were further empowered to build poor-houses, at the charge of the parish, for the reception of the impotent poor only. The justices were further empowered to assess all persons being of sufficient ability, for the relief and maintenance of their children, grandchildren, and parents. The parish officers were also empowered to bind as apprentices any children who should be chargeable to the parish.

These simple provisions were in course of time greatly perverted, and so many abuses were practically engrafted upon the statute, that it became an instrument of m general demoralization than was ever sanctioned by leg tive authority. It would greatly exceed any reaso limits to trace the progress of these abuses. The mo jurious practice was that which was established in and ab the year 1795, when, in order to meet the pressure upo labouring population caused by the high price of prov an allowance was made out of the parish fund to ever bourer in proportion to the number of his family, and out reference to his being employed or without employ This allowance fluctuated with the price of flour, and scale was so adjusted as to return to each family the which a given quantity of flour would cost beyond the in years of ordinary abundance. This plan was dou conceived in a spirit of benevolence, but the readiness which it was adopted in all parts of England clearly the general want of sound views on the subject. If t had been left to take their course in England, as they in Scotland, the labourer's wages would have enabled to purchase the same or nearly the same amount of visions and other articles of necessary consumption as b the advance, and when the necessity for such a rise in had passed away everything would have reverted former state. Under the allowance system the lab was made to receive a part of his earnings in the form parish gift, and as the fund out of which it was provide raised from the contributions of those who did not labourers, as well as of those who did, it followed th labourers were degraded from the condition of honou independence to that of parish paupers, and that th ployers, being able in part to burthen others with the ment for their labour, had a direct interest in perpet the system. Accordingly it was found that a constan rapid deterioration took place in the character of t bouring agricultural population, and that they becam able to obtain a rate of wages adequate to their without parish relief, however moderate might be the of the necessaries of life.

There are no accounts of the sums levied year by year England and Wales for the relief of the poor, before th ginning of the present century. The average expen for each of the three years 1783-4 and 5, was 1,91 the earliest account after that date is for 1801, whe expenditure amounted to 4,017,871*l*., the assessments h been more than doubled in 17 years. It will be seen the following table how little connection there has since that time between the sums expended for relief the price of corn:—

Years.	Sums expended for the Relief of the Poor.	Average Price of Wheat per Quarter.		Years.	Sums expended for the Relief of the Poor.	A
	£.	s.	d.		£.	s.
1801	4,017,871	115	11	1826	5,928,501	[illegible]
1803	4,077,891	57	1	1827	6,441,088	[illegible]
1811	6,656,105	92	5	1828	6,298,000	[illegible]
1814	6,294,581	72	1	1829	6,332,410	[illegible]
1815	5,418,846	63	8	1830	6,829,042	[illegible]
1816	5,724,839	76	2	1831	6,798,888	[illegible]
1817	6,910,925	94	0	1832	7,036,968	[illegible]
1818	7,870,801	83	8	1833	6,790,799	[illegible]
1819	7,516,704	72	3	1834	6,317,255	[illegible]
1820	7,330,256	65	10	1835	5,526,418	[illegible]
1821	6,959,249	54	5			
1822	6,358,702	43	3	1836	4,717,630	[illegible]
1823	5,772,958	51	9	1837	4,044,741	[illegible]
1824	5,736,898	62	0	1838	4,123,604	[illegible]
1825	5,786,989	66	6	1839	4,421,714	[illegible]

The extent to which the pauperising of the labour England was carried had long been viewed with alarm, had formed the subject of many parliamentary inqui without producing any substantial amendment, until a commission was appointed by the crown, consisting bishops of London and Chester, Mr. Sturges Bourne, Senior, and five other gentlemen, under whose direct quiries were carried on throughout England and Wa the actual condition of the labouring class in every pa was ascertained with the view of showing the evils of isting practice, and of suggesting some remedy. The la this inquiry was exceedingly great, but in a compar short time a Report was presented by the commissioner completely explained the operation of the law as adm tered, with its effects upon different classes, and su remedial measures. This Report was presented in Feb

1834, and was followed by the passing, in August, 1834, of the Poor Law Amendment Act, in which the principal recommendations of the commissioners were embodied.

The chief provisions of this law are—the appointment of a central board of three commissioners for the general superintendence and control of all bodies charged with the management of funds for the relief of the poor. The further appointment of nine assistant-commissioners, each one of whom should be attached to some particular district, in order to carry out practically the orders of the central board; the whole to be subject to the direction of the secretary of state for the home department. The administration of relief to the poor is placed under the control of the commissioners, who make rules and regulations for the purpose, which are binding upon all the local bodies. They are empowered to order workhouses to be built, hired, altered, or enlarged, with the consent of the majority of the board of guardians. One very important power given to them is that of uniting several parishes for the purposes of a more effective and economical administration of poor relief, but so that the actual charge in respect of its own poor is defrayed by each parish. These united parishes, or unions, are managed by boards of guardians annually elected by the rate-payers of the various parishes, but the masters of workhouses and other paid officers are under the orders of the commissioners, and removable by them. The system of paying wages partly out of poor-rates is discontinued, and except in extraordinary cases, as to which the commissioners are the judges, relief is only to be given to able-bodied persons or to their families within the walls of the workhouse. Another branch of the poor-law, which was materially altered by the act of 1834, was that relating to illegitimate children. The system of relief which was previously followed was so far from acting as a check on bastardy, that it was actually a great encouragement to it. On the birth of a bastard child, the parish officers generally obtained an order of affiliation upon the putative father, and the money paid under that order was often abusively received by the mother. In this manner a woman of loose habits was placed in more comfortable circumstances than a virtuous woman; she was even sought in marriage as a prize, while a widow with an equal number of children, having no such allowance, had no chance of making a second marriage. Under the new law, the facilities for obtaining orders upon putative fathers are diminished, the mother and child are generally relieved in the workhouse, and the money paid under the order is always received by the parish-officers and accounted for by them. The operation of this part of the law may have been productive of hardship in some cases, and it is objected that it sets little restraint on the male; but in practice it has been found to diminish in a sensible degree the proportion of illegitimate births chargeable to the parish.

These are the principal provisions of this very important statute, which, upon a careful review of all the facts which have been ascertained before and since its enactments, may be said to have answered the ends proposed. In some of its minor details it may still be susceptible of improvement. But it is no small testimony to the judgment and sagacity of those who suggested the provisions of this law, and of those who have carried them into operation, when we state that the law has now been in operation for more than five years; that it has encountered great opposition; and yet that it has been found adapted to nearly every emergency that has occurred.

The number of unions formed and declared under the Poor Law Amendment Act, from its commencement to the 31st of May, 1839, was 597, including 13,641 parishes, with a population of 11,751,342 souls. The saving in money effected by this reform is not its most important feature, although the benefit on that score will scarcely be denied. If the expenditure of 1839 be compared with that of 1834, the year which immediately preceded the operation of the act, it will appear that the diminution amounted to 1,895,540*l.*, or 29 per cent., but it is hardly fair to select for such a comparison either 1834, when the previous inquiries of the commissioners had already fixed the attention of the public upon the subject, and had forced those by whom the parish funds were administered to adopt measures of economy, or 1839, in which the high price of every kind of provisions and the consequent falling off in the demand for labour had necessarily added to the number of claimants for relief and to the extent of their demands. If, in consideration of these facts, we compare the expenditure of 1837 with that of 1833, in which two years the price of provisions was nearly the same, it will appear that the saving amounted to 2,740,658*l.*, or more than 40 per cent. Under the former administration of the law it had been customary in some parts of the kingdom for farmers to discharge their labourers in the winter, at which season they and their families became wholly chargeable to the parish. This custom no longer prevails. Labourers, being unable to obtain that kind of relief without entering the poor-house and submitting to its regulations, now refuse to work at any season for those who will not continue to employ them throughout the year, and by this means the burthen is so far thrown upon those who ought to bear it. The good effect of this change is further experienced in the greater amount of labour bestowed upon the soil, and its consequent improved productiveness, which is so much clear gain to the country.

The condition of the labouring classes in Ireland has long been a reproach to the legislation of the United Kingdom. Until the passing of the Act 1 & 2 Victoria, c. 56, which received the royal assent on the 31st July, 1838, no provision had been made by law for the relief of the helpless or the destitute in that part of the kingdom. The evils of poverty had long reached to such a height as to defy the efforts of private benevolence, and misery of the most appaling kind was of such universal occurrence, that it had almost ceased to excite commiseration or sympathy. Apart from all private and individual hardship, there resulted this public evil, that the possession of land, the only sure resource against starvation, became a matter of such urgent necessity, that the peasants bid against one another to obtain it, until the produce beyond the rent was barely sufficient for their sustenance, while the mode of cultivation was such as to keep the soil far below its productive powers. This evil still exists in nearly its full strength, and it will be many years before any considerable progress can be made in effecting a remedy, but a beginning has been made by the introduction of the Irish Poor Law, which affords relief against destitution by other means than the possession of land. The introduction of the system into Ireland is yet too recent to justify any opinion as to its success. Up to the 25th of March, 1839, the Poor Law Commissioners had succeeded in forming twenty-two unions, comprising an extent of 2,950,163 statute acres, with a population, according to the returns of 1831, amounting to 1,517,344; and arrangements had been made for declaring eighteen other unions, extending over 2,403,274 acres, and having a population of 1,140,213. In April, 1840, more than 100 unions had been formed by the commissioners in Ireland; and it is confidently expected that the whole of that country will have been divided into unions before the end of 1840.

One important consequence which has resulted from the better management of the poor, and which is calculated to produce an important effect on their future condition, is the adoption of plans for the training and instructing of children resident in workhouses. Under the administration of the unamended law little or nothing was done towards this object, and in almost every case the child whose misfortune it was to be brought up at the charge of the parish, continued through life dependent upon others for subsistence, and often followed a course of systematic dishonesty. Moral criminality in such cases might be more fairly chargeable against society, which had neglected to give a proper direction to the young pauper's habits, than against the individual delinquent; and society has paid dearly for the neglect. The system of moral, intellectual, and industrial training which has been to some extent engrafted upon the administration of the amended law, is calculated to bring up the children of the workhouse to be useful members of society. It has been well observed in a Report on this subject drawn up by Dr. Kay, that 'the state is *in loco parentis* to the pauper children who have no natural guardians, and the interest it has in the right discharge of its responsibilities may be illustrated by supposing the government had determined to require direct instead of indirect service in return for education. If the army and navy were recruited by the workhouse children, it is evident that it would be the interest of the state to rear a race of hardy and intelligent men—instructed in the duties of their station—taught to fear God and honour the queen. The state has not less interest, though it may be less apparent, in supplying the merchant service with sailors, and the farms and the manufactories of the country with workmen, and the households of the upper and middle classes with domestic servants: it has the most positive and direct interest in adopting measures to prevent the rearing of a race of prostitutes and felons. It may be questionable how far it would be proper to permit the pauper children to volunteer for service in the army and navy, and to train them accordingly; but the duty of rearing these children in religion and industry, and of imparting to them such an amount of secular knowledge as may fit them to discharge the duties of their station, cannot be doubted.'

PAUSA'NIAS, son of Cleombrotus, was of that royal house in Sparta which traced its descent from Eurysthenes. Aristotle calls him 'king,' but he only governed as the cousin-german and guardian of Pleistarchus, who succeeded to the throne on the death of Leonidas.*

Pausanias comes principally into notice as commander of the Grecian army at the battle of Platæa. The Spartan contingent had been delayed as long as was possible, but owing to the representations made by the Athenian ministers at Lacedæmon, it was at last despatched, though not until the Persians had advanced into Bœotia. This delay had however one good effect, that of taking the Argives by surprise, and defeating their design of intercepting any troops hostile to Persia, which might march through their territory. The Spartans, under the command of Pausanias, got safe to the Isthmus, met the Athenians at Eleusis, and ultimately took up that position which led to the battle of Platæa.

The result is well known. Pausanias, elated by his success, took all methods of showing his own unfitness to enjoy good fortune. Being sent with twenty ships, and in the capacity of commander-in-chief of the confederates, to the coast of Asia Minor, by his overbearing conduct he disgusted the Greeks under his command, and particularly those Asiatic Greeks who had lately revolted from Persian rule. To his oppression he added an affectation of Eastern luxury; and what we know of Spartan manners seems to lead to the conclusion that no mixture could possibly be more repugnant to persons accustomed at once to Persian elegance and Ionic refinement, than a clumsy imitation of both, such as the conduct of Pausanias probably presented. Prejudice in favour of the Athenians, who were of the Ionic race, was also active; intrigues commenced, the Athenians encouraged them, and Pausanias was recalled.

Much criminality was imputed to him by those Greeks who came to Sparta from the seat of war, and his conduct was clearly more like the exercise of arbitrary power than of regular military command. He was accordingly put on trial. Private and public charges was brought against him; from the former he was acquitted, but his Medism (or leaning to Persia) seemed to be clearly proved. Dorcis was sent in his place, but the Spartan supremacy had received its death-blow, and thenceforward Lacedæmon interfered only sparingly in the prosecution of the contest with Persia. Pausanias however, with the feelings of a disappointed man, went in a private capacity to the Hellespont, on pretence of joining the army. After the taking of Byzantium, which happened during his command, he had winked at the escape of Persian fugitives of rank, and by means of an accomplice had conveyed a letter to the Persian monarch, containing an offer to subjugate Greece to his dominion, and subjoining the modest request of his daughter to wife. A favourable answer had elated him to such a degree as to disgust the allies in the manner already stated. On his second journey he was forcibly prevented from entering Byzantium, upon which he retired to a city in the Troad. There too his conduct was unfavourably reported at home, and a messenger was despatched with orders for his immediate return, under threats of a declaration of war against him. Pausanias returned, but it was still hard to bring home any definite charge against him, and the Spartans were shy of adducing any but the strongest evidence. At last however one of his emissaries having discovered that he was, like all his predecessors, the bearer of orders for his own death, as well as of his master's treason, denounced him to the Ephori. By their instructions, this slave took sanctuary, and through a partition made by a preconcerted plan in a hut where he had found refuge, they had the opportunity of hearing Pausanias acknowledge his own treason, during a visit which he paid to his refractory messenger. The Ephori proceeded to arrest Pausanias, but a hint from one of their number enabled him to make his escape to the temple of Minerva of the Brazen House, only however to suffer a more lingering death. He was shut up in the temple, and, when on the brink of starvation, brought out to die (B.C. 467). By such means Spartan superstition was satisfied, and the actors in the tragedy held themselves innocent of sacrilege. Thirty-five years after, a contest arose on this very point. [PERICLES.]

The Hippodrome of Constantinople still contains, although sadly mutilated, the brazen tripod which Pausanias dedicated at Delphi, with an inscription to the effect that it was in gratitude for having destroyed the Persian host.

(Thucyd., i. 132, &c.; Gibbon's *Decline and Fall of the Roman Empire*, vol. iii., ch. 17, p. 22, ed. 8vo., note; and Clarke's *Travels*, ii., p. 58.)

PAUSA'NIAS, the author of the 'Description or Itinerary of Greece' (Ἑλλάδος Περιήγησις), appears, according to his own account, to have been a native of Lydia (v. 13, 7); but the passage cited hardly proves this. Little or nothing is known of him, except what may be collected from his own work. The 'Description of Greece' consists of ten books: the first contains the description of Attica and Megaris; the second, Corinthia, Sicyon, Phlius, and Argolis; the third, Laconica; the fourth, Messenia; the fifth and sixth, Elis; the seventh, Achæa; the eighth, Arcadia; the ninth, Bœotia; and the tenth, Phocis.

It appears from incidental notices in the work, that Pausanias not only visited the places which he has described, but also many other remote parts. He must have been at the temple of Ammon, in Libya (ix. 16, 1); at Cnossus in Crete; in the island of Delos (ix. 40, 3); at Capua in Campania (v. 12, 3); and at Rome (viii. 46, 5). A traveller who visited all these places must have visited many others. Pausanias made his tour of Greece in the time of Antoninus Pius. In speaking of the Odeion of Herodes, he says that he had not described it in his account of Attica (i.), because it was not built when he was writing that part of his work (vii. 20, 6). Herodes died in Attica about the end of the reign of M. Aurelius.

The work of Pausanias is different in character from that of Strabo: it contains no general geographical description of the surface of the country; it is a description of places only. He describes each place as he comes to it, and every object in each place in the order in which it comes before him. His description is minute and generally complete; he seems to have busied himself as a man would do if he were making an inventory or catalogue. There is no attempt to set off the things which he describes by any ornament of language; and yet such is the power of beautiful objects when portrayed in the simplest words, that some of his descriptions are beautiful merely by virtue of the beauty of the objects described. Buildings, monuments, statues, and paintings were the chief objects which he has registered: in connection with them he collected and recorded local traditions and mythological stories in abundance. Natural objects, as rivers, mountains, caves, are also noticed in his description; but nearly always in connection with the mythological stories attached to them. Yet he was a careful observer of natural phenomena, and many curious facts of this kind are scattered through his work. In describing a kind of marble (λίθος κογχίτης) which was much used in the buildings of Megara, he observes that it is very white, softer than other stone, and full of sea-shells (i. 44, 6). In another passage (vii. 24) he has some curious remarks on earthquakes. His work also abounds in historical facts, many of which are exceedingly valuable. He not unfrequently digresses, something after the manner of Herodotus, whom he resembles in some degree, and consequently a man will find in his work much curious matter that he would never expect to see there. Pausanias was superstitious, and it would be hard to find an antient usage, however absurd, which he does not treat with respect. This work contains an inexhaustible treasure of facts, historical, topographical, and mythological its value and accuracy as a topographical description have been well tested by some of our own countrymen, especially Leake. The style of Pausanias has often been censured as obscure, and his sentences as ill constructed. There is some truth in this; but if we deduct the passages that are corrupt, and some that are scarcely intelligible without ocular view of the places described, it can hardly be said that he is a difficult writer to those who have studied him.

Pausanias, in his numerous accounts of works of art, although he seems to have described with equal attention and indiscriminately all that came under his eye, has left us many notices of the highest value; and several of the most important productions of antient painting would be known to us merely by name but for his circumstantial detail, as the great works of Polygnotus at Delphi ('Phocica,' c. 25-31), and the paintings by various artists in the Poecile at Athens, and others of minor importance.

---

* Thucydides however has an expression (i. 132) which almost appears to justify this use of the word βασιλεύς, 'king.'

Although Pausanias made his tour of Greece nearly five hundred years after the flourishing period of Grecian art, and notwithstanding the extensive system of plunder which had been carried on for centuries, he still found several hundred specimens of painting; and of sculpture, probably owing to the more durable and less portable nature of the material used in that art, he found a much greater number. He has named altogether about two hundred artists of all descriptions: nine only however are painters of great fame, Polygnotus, Micon, Panaenus, Euphranor, Parrhasius, Nicias, Apelles, Pausias, and Protogenes. The proportion of sculptors is much greater, for the reason already mentioned: we have notices of works of Phidias, Alcamenes, Polycletus, Myron, Naucydes, Calamis, Onatas, Scopas, Praxiteles, Lysippus, and others. Though Pausanias, in matters of art, was certainly not a critic, yet perhaps in no instance does he confound an obscure with a celebrated name; his attention appears to have been generally engrossed by the parts and detail of what he describes, and seldom, if ever, by the style and composition, or any of the higher merits of art. This has been adduced as a serious objection to his work; but so far from that, it rather enhances its value than otherwise. Pausanias has described impartially all that he saw, without distinction of either style or school; whereas an artist probably, or even a connoisseur, biassed by the prejudices of his own peculiar education, would have selected only that which might have happened to coincide with his own taste, neglecting everything else as unworthy of notice, and thus handing down only a very partial and imperfect account. Certainly no such objection can be made to the work of Pausanias. On the contrary, somewhat more of system would have been desirable in the descriptions of the more important works; 'but the minute and scrupulous diligence,' says Fuseli, 'with which he examined what fell under his own eye, amply makes up for what he may want of method or of judgment. His description of the pictures of Polygnotus at Delphi, and of the Jupiter of Phidias at Olympia (v. 10), are perhaps superior to all that might have been given by men of more assuming powers, mines of information and inestimable legacies to our arts.' (Introduction, *Works*, vol. ii.)

The first edition of Pausanias is that of Venice, 1516, fol., Ald.: it is said to be very incorrectly printed. An edition, begun by Xylander and finished by Sylburg, was printed at Frankfort, 1583, fol., and again at Hanau, 1613. The edition of Kühn, Leipzig, 1696, fol., is accompanied with the Latin translation of Romulus Amasaeus, which first appeared at Rome, 1547, 4to. The edition of Siebelis, 5 vols. 8vo., Leipzig, 1822, contains a corrected text and the translation of Amasaeus improved, with an elaborate commentary and complete index. The edition of Bekker, Berlin, 1826-1827, 2 vols. 8vo., is an exact copy of the Paris MS., 1410, in every instance in which the editor has not noticed his deviation from that text: this edition has a very good index. A new German translation, by Wiedasch, appeared at Munich, 1826-1833. The best French translation is by Clavier. There is an English translation by Thomas Taylor, the translator of Aristotle and Plato.

PAU'SIAS, a native of Sicyon, after he had learned the rudiments of his art from his father Brietes, studied encaustic in the school of Pamphilus, where he was the fellow-pupil of Apelles and Melanthius. Pausias was the first painter who acquired a great name for encaustic with the cestrum: he excelled particularly in the management of the shadows; his favourite subjects were small pictures, generally of boys, but he also painted large compositions. He was the first also who introduced the custom of painting the ceilings and walls of private apartments with historical and domestic subjects: the practice however of decorating ceilings simply with stars or arabesque figures (particularly those of temples) was of very old date.

Pausias undertook the restoration of the paintings of Polygnotus at Thespiae, which had greatly suffered through time, but he was judged inferior to his antient predecessor, for he contended with weapons not his own; he generally worked with the cestrum, but the paintings of Polygnotus were with the pencil, which Pausias consequently also used in this instance.

The most famous work of Pausias was the *sacrifice of an ox*, which in the time of Pliny was in the hall of Pompey. In this picture the ox was foreshortened, but to show the animal to full advantage, the painter judiciously threw his shadow upon a part of the surrounding crowd, and he added to the effect by painting a dark ox upon a light ground.

Pausias in his youth loved a native of his own city, Glycera, who earned her livelihood by making garlands of flowers and wreaths of roses, which led him into competition with her, and he eventually acquired great skill in flower painting. A portrait of Glycera with a garland of flowers was reckoned amongst his masterpieces; a copy of it was purchased by L. Lucullus at Athens, at the great price of two talents (about 432*l.*). This picture was called the 'Stephanoplocos,' or garland wreather. Pausias was reproached by his rivals as being a slow painter, but he silenced the censure by completing a picture of a boy, in his own style, in a single day, which on that account was called the 'Hemeresios,' or work of a day. (Pliny, *Hist. Nat.*, xxxv. 11, 40.)

Pausanias mentions two pictures by Pausias at Epidaurus, the one a Cupid with a lyre in his hand, his bow and arrows lying by his side; the other, the figure of Methe, or drunkenness, drinking out of a glass, through which his face was seen (ii. 27). Pliny mentions two pupils of Pausias, his son Aristolaus, a painter 'e severissimis,' and a certain Mechopanes, who was distinguished for a high finish and an excessive use of yellow: he was also hard in colouring, yet he had his admirers notwithstanding these peculiarities. We may collect from the allusion of Horace (*Sat.*, ii. 7, 95) that the pictures of Pausias were well known at Rome.

PAUSE. [ORATORY.]

PAU'SSIDÆ, a family of Coleopterous insects, the precise affinities of which have not yet been satisfactorily determined. By Latreille the Paussi are placed between the *Scolytidæ* and the *Bostrichidæ*; but Mr. Westwood (who has devoted much attention to this group of beetles and has published a monograph on them in the sixteenth volume of the 'Linnean Transactions') is of opinion that the Paussidæ possess affinities with the Trogositarii, and are still more nearly allied to the Cucujidæ.

These insects are usually of small size, the largest known species being less than half an inch in length, and their colouring generally consists of various shades of brown, and they are not unfrequently adorned with black markings. The form of the body is generally short, rather broad, and somewhat depressed; the head, in most of the species, is free (*i.e.* not hidden by the thorax), and joined to the thorax by a kind of neck; the thorax is narrower than the elytra, and is almost always divided transversely near the middle by an indentation, in which case the fore part is usually broader than the hinder, produced at the sides so as to form projecting angles; the elytra are rather soft, and in most of the species are of subquadrate form, truncated at the apex, and leaving exposed the terminal segment of the abdomen; the outer posterior angle of the elytra is generally furnished with a small tubercle. The legs are in most species broad and compressed, and of moderate length; the tarsi are five-jointed in some, and apparently in others there are but four. The antennæ are remarkable for their large size and curious forms; in most of the species they consist of a large inflated club, about equal in size to the head and thorax taken together, and varying in form according to the species: the most common form of this knob is that of an oval more or less elongated, and with an angular projection on the outer side at the base; this club is joined by a smaller joint to the head.

Between twenty and thirty species of this family are known, a great portion of which are figured and described by Mr. Westwood in the monograph before alluded to, and in a supplement to this monograph published in the second volume of the 'Transactions of the Entomological Society,' to which works the reader is referred for a more detailed account of these very curious insects. Of their habits little is known; they are confined to the Old World, and almost entirely to the tropical portions. They are said to be nocturnal, and are supposed to live in wood or under the bark of trees: most of the specimens in cabinets have been found in newly-built houses. One species is said, when touched, to make discharges of some volatile fluid, in the same manner as the species of *Brachinus*.

The family Paussidæ contains the six following genera: *Paussus*, *Hylotorus*, *Platyrhopalus*, *Cerapterus*, *Pentapla-*

tarthrus, and *Trochoideus*. In the first three of these genera the antennæ are two-jointed, and the abdomen is of a quadrate form.

The genus *Paussus* is distinguished by the absence of ocelli on the head, and by the ultimate joint of the labial palpi being elongated.

In *Hylotorus* the head is furnished with two ocelli, and this genus moreover differs from *Paussus* in having the head immersed in the thorax; the great club of the antenna is thickest at the base, and somewhat curved and pointed at the opposite extremity.

Platyrhopalus has all the essential characters of *Paussus*, but differs in having the joints of the labial palpi equal.

In the genus *Cerapterus* the antennæ are large, broad, and compressed, and appear to be composed of ten joints, most of which are very distinct; the terminal joint is the largest; the preceding joints (if we except the basal one) are transverse and all of equal width.

In *Pentaplatarthrus* the antennæ gradually increase in size from the base to the apex, and are composed of six joints. The basal joint is longer than broad; the second is transverse; the three following joints are nearly equal in width and length, and the terminal joint is almost spherical.

The genus *Trochoideus* differs from all the preceding genera in having an ovate form of body; the thorax is rather narrower than the elytra; its sides are rounded, the broadest part in front, and there is apparently no transverse indentation. The head is large and rounded, and deeply inserted in the thorax. The antennæ are composed of two small basal joints, which are longer than broad, and terminate in a large oval club. The legs are more slender than in other species of this family, and the tarsi are represented as having only four joints.

PAUW, CORNELIUS, born at Amsterdam in 1739, studied at Göttingen, and was afterwards made canon of Xanten, in the duchy of Cleves. He applied himself to literature, and wrote several works in French on the history and physiology of various nations and countries. His 'Recherches historiques sur les Americains' contain some curious information, many sensible reflections, and also many unsupported assertions set forth in a dogmatic tone. Pauw had not visited America, and his object seems to have been to collect all the passages which he could find in other writers, and which could support some preconceived opinion of his concerning the great inferiority of that part of the world, its productions, and its native races. (Pernety, *Dissertation sur l'Amérique et les Américains contre les Recherches historiques de M. de Pauw*, which is found at the end of some editions of Pauw's work.) In his chapter on Paraguay, Pauw shows himself particularly hostile to the Jesuits. His 'Recherches sur les Grecs,' in which he had better guides, is written with greater sobriety of judgment; but even in this work, his dogmatic spirit is perceptible. Pauw published also 'Recherches sur les Egyptiens et les Chinois.' The French Revolution, and the subsequent invasion of the duchy of Cleves, deprived Pauw of his peace of mind. He became dejected, and burnt all his papers, among others his 'Recherches sur les Germains,' which is said to have been the most elaborate of his works, but which was never printed. He died at Xanten, in 1799.

Another member of the same family, John Cornelius Pauw, born at Utrecht towards the end of the seventeenth century, was a good classical scholar, published editions of several Greek classics, and wrote notes on Pindar, and also a 'Diatriba de Alea Veterum.'

PAUXI. [CRACIDÆ, vol. viii., p. 129.]

PAVEMENT. [ROADS.]

PAVI'A, THE PROVINCE OF, in the Lombardo-Venetian Kingdom, is bounded on the north by the province of Milan, on the east by that of Lodi, west by the Sardinian territory, from which it is separated by the river Ticino, and on the south partly by the Sardinian territory and partly by the duchy of Parma, being separated from both by the Po. The province of Pavia is the smallest of the Lombard provinces, but it is one of the most fertile, being entirely in the fine plain of the Po. It produces corn, wine, fruit, hemp, and has good pasture land. The length is about 40 miles from north-west to south-east, but the breadth does not exceed 10 miles. The population amounts to 157,600 inhabitants. (*Bollettino Statistico di Milano* 1838.) The province is divided into eight districts: Pavia, Belgioioso, Bereguardo, Corte, Olona, Rosate, Binasco, Abbiate Grasso: reckoning in all 193 communes. There is no town of any importance except Pavia, but there are numerous large villages. Two navigable canals, the Naviglio Grande and the Canale of Pavia, cross the province, and supply a water communication between Milan and the Lago Maggiore and the Ticino and Po, and by the latter river with the Adriatic.

PAVI'A, THE TOWN OF, is situated on the left or eastern bank of the Ticino, a few miles above its junction with the Po. A handsome covered bridge over the river connects Pavia and the suburb on the right bank, called Borgo Ticino. A fine street which crosses the town in its length leads to this bridge. The cathedral, which is a modern structure, was rebuilt in the last century; it contains some good paintings. The oldest church in Pavia, and perhaps one of the oldest in Italy, is that of San Michele, which is asserted by D'Agincourt, Rosmini, and other antiquarians, to have been built in the sixth century of our æra; whilst another writer, San Quintino (*Dell' Architettura Italiana durante la Dominazione Longobardica*, Brescia, 1829), maintains that the old church was burnt, together with the greater part of the town, by the Hungarians in the early part of the tenth century, and that the present church was built in the eleventh century. Several old and curious basso-rilievos adorn this church, as well as some frescoes of the age of Giotto. One of the rilievos on the outer wall of the church seems to belong to an early period of the Longobard dominion in Italy, when that nation was still Arian: it represents the annunciation of the Virgin, in which the child is represented as already grown up. (Valéry, *Voyages en Italie*.) If this be a correct interpretation of this monument, it would go far to prove that the church really dates from the sixth century, before the Longobards forsook the Arian creed through the influence of Theodolinda, their queen. The vast church Del Carmine, which was built in the fourteenth century, contains some valuable paintings. That of Santa Maria Coronata was built by Bramante, and is also rich in paintings. The once handsome church of San Pietro 'in Cielo d'oro,' noticed by Dante (*Paradiso*, x.), as containing the tomb of the learned Boëthius, the minister of Theodoric, has long since been suppressed, with the adjoining monastery, and, when Valery visited it twelve years since, was used as a military storehouse. It was in his confinement at Pavia that Boëthius composed his book 'On the Consolations of Philosophy.' In the same church of San Pietro was the mausoleum of Liutprand, one of the most illustrious of the Longobard kings, which has also disappeared.

Pavia is chiefly known for its university, the first in Italy, which, among its professors in our own times, can boast of the names of Scarpa, Volta, Configliacchi, Brugnatelli, Tamburini, and other distinguished men. The university contains thirteen colleges; and the faculties are those of law, medicine, and philosophy. The instruction is liberal and untrammelled, and the professors are well remunerated: several chairs, such as those of statistics, diplomacy, history of philosophy, and pedagogy, have been added of late years. Pavia has long been renowned for its medical and surgical instruction. The former library of the university was plundered by the French in the wars of Louis XII. and Francis I; the present library was formed in the last century by Count Firmian, the enlightened minister of the empress Maria Theresa, who was the restorer and patroness of the university. A museum of natural history, a cabinet of anatomy, and a botanical garden are annexed to it. The number of students is about 1400. Three colleges, Caccia, Borromeo, and Ghislieri, the first two founded by the noble families of those names, and the third by Pope Pius V., support about 120 students gratuitously. The college Borromeo is a magnificent building. Further details concerning the university of Pavia are given in Nos. 5 and 16 of the 'Quarterly Journal of Education.' Pavia contains 23,600 inhabitants, according to the census of 183[illegible]. It is a bishop's see, has a large hospital, a house for foundlings, and other benevolent institutions. Several palaces of the nobility contain galleries of paintings.

Pavia, called Ticinum by the Roman writers, was a town of Cisalpine Gaul, but little mention is made of it in Roman history. The name of Pavia, or Papia, is first mentioned in the history of the Longobards, who made it the residence of their kings, whose palace however no longer exists. It went through the same vicissitudes as the other Lombard towns; was a republic, afterwards had its tyrants, then became subject to the dukes Visconti of Milan, and lastly came under the dominion of the House of Austria. It was near Pavia that Francis I. was defeated and taken prisoner by the troops of Charles V. in 1525. In the years 1527 and 1528, it was twice taken and plundered by the French, and almost entirely depopulated. In 1796, after Bonaparte had invaded Lombardy, an insurrection against the French broke out at Pavia, which was put down by force, and the town given up to indiscriminate pillage.

Five miles distant from Pavia, on the road to Milan, is the splendid Carthusian monastery suppressed by Joseph II., which had an income of about one million of livres (40,000*l.*). It was built by Gian Galeazzo Visconti, duke of Milan, whose monument is in the church: the church is rich in sculptures, marble, and fresco paintings.

(*La Certosa di Pavia descritta ed illustrata con Tavole*, by Durelli, fol., Milan, 1823-30.)

PA'VIA is a small division of the natural order Æsculaceæ, differing from Æsculus itself in little except its converging petals and spineless fruit. It consists of small trees or bushes with yellow or red flowers, inhabiting North America, and often cultivated in shrubberies under the name of the Yellow or Scarlet Horse-chesnut. Two species, P. indica and Punduana, have also been found in the colder parts of India, but they have not yet been introduced into our gardens. With us the American species are usually short-lived and of no value for their timber; the former circumstance is probably owing to their being grafted upon the common horse-chesnut, a stock that does not suit them. They should always, if possible, be raised from seeds, which are annually imported from the United States.

PAVING. [ROADS.]

PAVO (the Peacock), a constellation of Bayer, which occupies a part of the space situated between Sagittarius and the South Pole. Its principal stars are as follows:—

PAVO'NIDÆ, Peacock family, Mr. Swainson's name for a family of Rasorial birds.

The genus *Pavo* of Linnæus stands next to *Didus* [DODO] in the *Systema Naturæ*, and is immediately succeeded by *Meleagris*, which is followed by *Crax*, *Phasianus*, *Numida*, and *Tetrao*.

Mr. Vigors admits no such family as *Pavonidæ* into his group of the *Rasores*; but its place is supplied by the *Phasianidæ*, a family which does not exist in Mr. Swainson's system. Mr. Vigors enters the family of *Phasianidæ* by the genus *Meleagris*, leaving the *Columbidæ* by the *Crowned Pigeon* of India (*Lophyrus*, Vieill.), which possesses the strongly formed leg and foot of *Meleagris*, but without the spurs, while at the same time it retains the bill of *Columba*. *Meleagris*, then, in conjunction with *Pavo*, Linn., and *Polyplectron*, Temm., commences Mr. Vigors's group of *Phasianidæ*, by the greater length of the hinder toe, in which character it resembles the *Columbidæ*, with the exception of its being articulated higher on the tarsus. *Lophorus*, Temm., and *Gallus*, Brisson, appear to Mr. Vigors to hold an intermediate station between the groups just mentioned and the true *Phasianus*, which, in his opinion, forms the type of the family. Some groups deviating from the latter genus (*Argus*, Temm., for instance) unite themselves, he thinks, to *Numida*, Linn., by the absence of the spur on the tarsus. The last-mentioned genus reconducts us, according to his views, to *Meleagris*, which it resembles in general appearance; while, at the same time, it approaches it with reference to the integrity of the tarsus, that of the true *Meleagris* possessing but a short and blunt excrescence, which exhibits only the rudiments of a spur. (*Linn. Trans.*, vol. xiv.)

Cuvier makes his *Paons* consist of the true peacocks (*Pavo*, Linn.) and *Lophophorus*. This group is followed by the *Dindons* (*Meleagris*, Linn.); the *Peintades* (*Numida*, Linn.); and the *Faisans* (*Phasianus*, Linn., including the cocks and hens (*Gallus*, Briss.); the true pheasants (*Phasianus Colchicus*, &c., including *Argus*, Temm.); the crested pheasants (*Houppifères*, Temm., *Phasianus ignitus*, &c.); the *Tragopans* (*Tragopan Satyrus*, &c.); and *Cryptonyx*. The *Tetraonidæ* immediately follow.

Mr. Swainson makes the *Pavonidæ*, the first family of the order *Rasores*, according to his arrangement, consist of the genus *Pavo*, with the subgenera *Argus*, *Polyplectron*, and *Meleagris*; the genus *Phasianus*, with the subgenera *Phasianus*, *Nycthemerus*, and *Ceriornis* (*Tragopan*); the genus *Gallus*; the genus *Lophophorus*; and the genus *Numida*.

Mr. G. R. Gray makes the *Pavoninæ* (the first subfamily of the *Phasianidæ*, according to his arrangement) consist of the genera *Polyplectron*, *Crossoptilon*, Hodgson (type *C. Tibetanus*), and *Pavo*. The fourth subfamily, according to the same author, is composed of the genera *Meleagris*, *Numida*, *Guttera*, and *Acryllium* (type *A. vulturinum*, Hardw.). (*List of the Genera of Birds*, 1840.)

In this work, *Phasianus*, with its subgenera, *Tragopan*, *Gallus*, and *Euplocamus*, are treated of under the title PHEASANTS.

Pavo. (Linn.)

Generic Character.—*Bill* convex, rather stout, curved towards the end, smooth at the base; cheeks partially naked; *nostrils* basal and open; head plumed and surmounted with an aigrette-like crest; sixth *quill* longest; tail-feathers eighteen; *tail-coverts* very long, large, and extensible in the male.

Two species only of this magnificent genus are recorded. One, *Pavo cristatus*, the *Common Peacock*, is universally well known.

The head is surmounted by an aigrette of four and twenty upright feathers. In the male the tail-coverts consist of feathers with loose barbs and of unequal size, the upper ones shortest, each terminated by numerous eyes or circlets of a metallic iridescent brilliancy: these the bird has the power of erecting into a circle or wheel, which presents, when the sun shines on it, an object of dazzling splendour which sets all description at defiance. The female has the aigrette, but has not the splendid ornament with which the male is gifted: her colours generally are sombre.

People usually talk of the peacock spreading its *tail*, but the rich display is composed, principally, of the tail-coverts. White soon saw the distinction. 'Having to make a visit to my neighbour's peacocks, I could not,' says he, 'help observing that the trains of those magnificent birds appear by no means to be their tails, those long feathers growing not from the *uropygium*, but all up their backs. A range of short brown stiff feathers, about six inches long, fixed in the *uropygium*, is the real tail, and serves as the fulcrum to prop the train, which is long and top-heavy when set an end. When the train is up, nothing appears of the bird before but its head and neck; but this would not be the case were those long feathers fixed only in the rump, as may be seen by the turkey-cock when in a strutting attitude. By a strong muscular vibration these birds can make the shafts of their long feathers clatter like the swords of a sword-dancer; they then trample very quick with their feet, and run backwards towards the females.'

This species is spread over the north of India and the islands of Malaisia in its natural state. It is the *Mohr* of the Mahrattas, according to Colonel Sykes, who describes the wild bird as abundant in the dense woods of the Ghauts; it is readily domesticated, and many Hindu temples in the Dukhun (Deccan) have, he tells us, considerable flocks of them. On a comparison with the bird as domesticated in Europe, the latter, both male and female, was found by the Colonel to be identical with the wild bird of India.

Colonel Williamson, in his account of peacock-shooting, states that he had seen about the passes in the Jungletery district surprising quantities of wild pea-fowls. Whole-woods were covered with their beautiful plumage, to which the rising sun imparted additional brilliancy. Small patches of plain among the long grass, most of them cultivated, and with mustard, then in bloom, which induced the birds to feed, increased the beauty of the scene. 'I speak within bounds,' continues Colonel Williamson, 'when I assert that there could not be less than twelve or fifteen hundred peafowls, of various sizes, within sight of the spot where I stood for near an hour.'

According to the same authority it is easy to get a shot in a jungle, but where the birds flocked together, which they do to the amount of forty or fifty, there was greater difficulty. Then they are not easily raised, and run very fast, so fast indeed, that the Colonel doubts whether a slow spaniel could make them take wing. They fly heavy and strong, generally within an easy shot: if winged only, they generally escape from their swiftness of foot. They roost on high trees, into which they fly towards dusk.

This is the *ταών* (Taon) and *ταώς* (Taos) of the Greeks; *Pavus* and *Pavo* of the antient Italians; *Pavon*, *Pavone*, and *Pagone* of the modern Italians; *Paon* of the French; and *Pfau* of the Germans.

Buffon and others say that the bird was introduced into Greece, whence it has been spread throughout Europe, in the time of Alexander the Great. Others again, with greater show of reason, assert that it was brought to Greece before the time of Pericles. Certain it is that the peacock is mentioned in two plays of Aristophanes, the 'Acharnians' and the 'Birds,' the first of which was represented in the third year of the 88th Olympiad, and the last in the second year of the 91st. Now Alexander was not born till the second year of the 98th Olympiad. Athenæus quotes from other old poets—Eupolis, for instance; nor does Aristotle speak of the bird in any other terms than those which would indicate that it had become very well known when he wrote: 'Some are jealous and vain like the peacock,' says Aristotle, when speaking of the qualities exhibited by certain animals. (*Hist. Anim.*, I. 1.)

Sir Robert Heron gives the following interesting account of the habits of these birds in a domesticated state:—'1814.—For a good many years I have attended to the habits of *Peafowl*, and for the last eleven have written down my observations. I find the individuals to differ as much in temper as human beings: some are willing to take care of the young ones of others, whilst some have pursued and killed them, and this whether they had a brood of their own or not. Some cocks have assisted in the care of young ones, whilst others have attacked them. An early hen frequently has a brood herself the next year. Age makes no difference in the number of the brood. I have had six from a hen a year old, and one from an old hen. The hens have frequently a great preference to a particular peacock. They were all so fond of an old pied cock, that one year, when he was confined in view, they were constantly assembled close to the trellice walls of his prison, and would not suffer a japanned peacock to touch them. On his being let out in the autumn, the oldest of the hens instantly courted him, and obtained proofs of his love in my presence. The next year he was shut up in a stable, and the hens then all courted his rival; for the advances in these birds are always made by the female.

'The japanned breed are, I believe, a variety originating in England. In Lord Brownlow's numerous breed of common, white, and pied, the japanned suddenly, in my memory, appeared amongst them. The same thing happened in Sir J. Trevelyn's flock of entirely the common sort; also in a breed of common and pied given by Lady Chatham to Mr. Thoroton; and in both cases to the extinction of the previously existing breed.' (*Zool. Proc.*, 1835.) The common peacock varies in its plumage accidentally. Thus there are pied varieties, and one entirely white. In this last the eyes or circlets of the train are shadowed out, as it were.

The female, like those of several other gallinaceous birds, is subject to putting on the plumage of the male when unfit for the reproduction of the species. Thus Lady Tynte had a favourite pied pea-hen, which had produced chickens eight several times. John Hunter relates that this bird having moulted when about eleven years old, the lady and family were astonished by her displaying the feathers peculiar to the other sex, and appearing like a pied peacock. In this process the tail (train), which became like that of the cock, first made its appearance after moulting. In the following year, having moulted again, she produced similar feathers. In the third year she did the same, and, in addition had spurs resembling those of a cock. She never bred after this change of plumage, and died the following winter in the hard frost of 1775-6. This specimen was in Sir Ashton Lever's museum, and the trunk with the atrophied ovary and oviduct, presented by Hunter, is preserved in the museum of the Royal College of Surgeons. In Hunter's account there is a note anticipating objections which will occur to most. It might be supposed, as is observed in this note, that this bird was really a cock which had been substituted for the hen, but the following facts put the point beyond doubt. First, there was no other pied pea-fowl in the county. Secondly, the hen had nobs on her toes, which were the same after her change. Thirdly, she was as small after the change as before; therefore too small for a cock. Fourthly, she was a favourite bird, and was generally fed by the lady, and used to come for her food, which she still continued to do after the change in her feathers.

Utility to Man.—To say nothing of this beautiful bird as an ornament to our parks and homesteads, it has recommendations of a more substantial nature. M. Lesson indeed says, 'leur chair est sèche et coriace, leur cri est rauque et désagréable.' We have nothing to say against the character given of their cry; but if we are to come to the other test, and sacrifice such a brilliant bird, we have only to observe that though the flesh of an old peacock or pea-hen may be—no doubt it is—dry and leathery, that of a young one is juicy and sapid. In antient times no great feast was complete, even in this country, without this bird, which was presented by the sewer well cooked, but in all its gorgeous plumage; and the adventurous knight made his solemn vow before the peacock and the ladies.

Pavo Japonensis, Aldrov.

Mr. Bennett, who had an opportunity of examining two living birds in the garden of the Zoological Society of London, in addition to stuffed specimens, gives the following accurate description of this species. Prevailing tints blue and green, varying in intensity and mutually changing into each other according as the light falls more or less directly upon them. In size and proportions the two species are nearly similar, but the crest of *Pavo Javanicus* is twice as long as that of *P. cristatus*, and the feathers of which it is composed are regularly barbed from the base upwards in the adult bird, and of equal breadth throughout. Head and crest interchangeably blue and green. A naked space on the cheeks, including the eyes and ears, is coloured of a light yellow behind, and bluish-green towards its fore-part. The feathers of the neck and breast, which are broad, short, rounded, and imbricated like the scales of a fish, are at their base of the same brilliant hue as the head, and have a broad, lighter, somewhat metallic margin; those of the back have still more of the metallic lustre. The wing-covers are of the general hue, with a deeper tinge of blue; the primary quill feathers are light chesnut. The tail-feathers and their coverts (train) are of a splendid metallic brown, changing into green; their barbs are extremely long, loose, silky, and somewhat decomposed; and the latter are almost all terminated by ocellated spots similar to those which mark the tail (train) of the common species, and of nearly the same size. As in it, they are of beautiful deep purple in the centre, which is about the size of a shilling; this is surrounded by a band of green, becoming narrow behind, but widening in front and filling up a kind of notch that occurs in the blue; then comes a broad brownish band; and lastly, a narrow black ring, edged with chestnut, all beautifully metallic, or rather presenting the hues of various precious stones when viewed in certain lights. Bill of a greyish horn-colour, rather longer and more slender than in the common species; iris deep hazel. Legs strong, naked, reticulated, dusky black; spurs large, and of the same hue. (*Gardens and Menagerie of the Zoological Society.*)

The bird above described is the *Pavo muticus* of Linnæus, who, as the name implies, described it as being devoid of spurs, relying probably on Aldrovandus, whom he quotes, and who figures it without spurs, describing it under the name of *Pavo Japonensis*. It is the *Japan Peacock* of Latham, the *Pavo spiciferus* of Vieillot, the *Pavo Aldrovandi* of Wilson, and *Pavo Javanicus* of Dr. Horsfield, who saw it in Java. Of these names, that of Aldrovandus has the priority; then comes that of Linnæus, which may mislead; then that of Horsfield; then that of Vieillot. We do not see anything objectionable in the name given by Aldrovandus, and therefore we have retained it.

It is not quite clear what Sir R. Heron means by the 'japanned breed' in the passage hereinbefore quoted; but ornithologists generally agree in considering the peacock last described as a distinct species. The figures of Aldrovandus were taken from drawings sent to the pope by the emperor of Japan. Shaw's figure (*Nat. Miscell.*) was engraved from an Indian drawing. Temminck's sketch of the head (*Hist. Nat. des Gallinacés*) was derived from Le Vaillant, who took it from an individual living at the Cape of Good Hope, whither the bird had been sent from Macao. Dr. Horsfield saw it in Java, and Sir Stamford Raffles in Sumatra, from which last country skins were sent to the Parisian Museum by MM. Diard and Duvaucel. From one of these Vieillot's figure (*Gal. des Ois.*) was taken. The living individuals formerly in the Gardens of the Zoological Society of London came from the Birman territory. The beautifully executed wood-cut in 'The Gardens and Menagerie of the Zoological Society' gives as perfect an idea of the species as can be derived from an uncoloured figure. No record of its habits in a wild state appears to have been published.

Meleagris. (Linn.)

The *Meleagris* of the antients was not a turkey, but a guinea-fowl (*Numida* of modern naturalists). Linnaeus however having given this as the generic name for the Turkeys, which were not known to the antients, ornithologists have continued it. Nor is this now of much consequence, certainly not of sufficient importance to change the name; for notwithstanding the confusion and doubt thrown over the subject by the learned discussions of the earlier modern ornithologists, it is generally known and satisfactorily proved that the Turkeys were only known to Europeans after the discovery of America, from which one species has been spread in a domesticated state over the greatest part of the civilized globe.

Generic Character.—*Bill* rather short, strong, curved, convex, vaulted, its base furnished with a naked skin; a fleshy caruncle surmounting the bill of an erectile nature and conical form. *Head* and *neck* surrounded with a wrinkled mammillated skin, hanging loose like a dewlap as far as the upper part of the breast. Hind toe touching the ground.

Two species are known: one, *Meleagris Gallopavo*, the original stock from which the domesticated turkey is derived; the other, *Meleagris ocellata*, a much more beautifully plumaged bird, did not exhibit in the only known specimen any trace of the tuft of hair on the breast. That character therefore is omitted above; but it is not certain that the last-mentioned species is entirely without this tuft, for the plumage of the specimen was damaged.

Meleagris Gallopavo.

Description of a wild Male.—Head small in proportion to the body, covered with a naked bluish skin, continued over the upper half of the neck and uneven with warty elevations, changeable red on the upper portion and whitish below, interspersed with a few scattered black hairs. The flaccid and membranous naked skin, also changeable on the lower part of the neck, extends downwards into large wattles. A wrinkled conical fleshy protuberance, capable of elongation and with a pencil of hairs at the tip, takes its rise from the base of the bill, where the latter joins the front. When this excrescence is elongated under excitement, it covers the bill and depends several inches below it. A tuft of long rigid black hair springs from the lower part of the neck at its junction with the breast, shooting out from among the plumage to the length of nine inches. The base of the feathers of the body, which are long and truncated, consists of a light fuliginous down; this part of the feather is succeeded by a dusky portion, which is again followed by a broad shining metallic band, varying from coppery colour or bronze to violet or purple, according to the play of the light, and the tip is a broad velvety band; but this last is absent in the feathers of the neck and breast. The general plumage presents a glancing metallic lustre, which is however less glossy on the lower part of the back and tail coverts. The wings are concave and rounded, not extending much if at all beyond the base of the tail. Quills 28; primaries blackish banded with white, secondaries whitish banded with blackish, tinged towards the back particularly with brownish-yellow. Tail fifteen inches in length at least, rounded at the extremity, the feathers 18, broad, and capable of expansion and elevation into a fan-[illegible]. The general colour of these feathers is brown mottled with black, crossed by numerous narrow undulating lines of the same. There is a broad black band near the tip, then a short mottled portion, and lastly a broad dingy yellowish band. The bird stands rather high on its robust red legs, the scales of which have blackish margins, and the blunt spurs are about an inch long: the claws are dusky. Bill reddish, but horn-coloured at the tip. Irides dark brown. Length nearly four feet; expanse of wings more than five.

Female wild Turkey.—Irides similar to those of the male. Bill and spurless legs less stout. Head and neck with less of naked skin, being partially covered with dirty grey feathers. Those on the back of the neck have brownish tips, and so produce a longitudinal band there. The short caruncle on the front is incapable of elongation; and though the tuft on the breast is not present in young hens, it is highly developed in the older ones, as may be seen in Mr. Audubon's celebrated plate. Prevailing hue of plumage dusky grey, each feather having a metallic band duller than in the male, then a blackish band, and lastly a greyish fringe. The blackish band is almost obliterated on the neck feathers and under surface. The whole plumage is more sombre than that of the male; there is less white on the primaries, and there are no bands on the secondaries. The colour of the tail is much as it is in the male. Length not exceeding three feet and a quarter.

Young wild Turkey.—The sexes are not easily distinguished till the skin of the head and neck begins to be tinged with red; but a tubercle on the breast of the young males at the approach of the first winter shows where the tuft is to be; during the second year the tuft becomes some three inches long; and during the third the bird is adult. It continues however to grow in dimensions and beauty for several years. The females attain their full size and colouring at the end of four years, when they have the breast tuft, which is not so full as it is in the male, and seldom exceeds the length of four or five inches.

The weight of these birds must either be now greatly diminished or the older writers must have been given to exaggeration, which last is the probable case. From 50 to 60lbs. has been mentioned, and a modern ornithologist of some celebrity, relying on old authorities, goes beyond the latter weight as the maximum, putting however the minimum at 20. The Prince of Musignano states that birds of 30lbs. weight are not uncommon, and that he had ascertained the existence of some which weighed 40lbs. Mr. Audubon gives the average at from 15 to 18lbs., and mentions a single instance, in the market at Louisville, where the weight was 36lbs.

Habits, &c.—The Prince of Musignano (*Continuation of* Wilson's *North American Ornithology*) informs us that the males, usually termed *Gobblers*, associate in parties of from ten to a hundred, and seek their food apart from the females, which either go about singly with their young, at that time about two-thirds grown, or form troops with other females and their families, sometimes to the amount of seventy or eighty. These all avoid the old males, who attack and destroy the young, whenever they can, by reiterated blows on the skull. But all parties travel in the same direction and on foot, unless the dog of the hunter or a river in their line of march compel them to take wing. When about to cross a river, they select the highest eminences, that their flight may be more sure, and in such positions they sometimes stay for a day or more, as if in consultation. The males upon such occasions gobble obstreperously, strutting with extraordinary importance, as if to animate their companions; and the females and young assume much of the pompous air of the males, and spread their tails as they move silently around. Having mounted at length to the tops of the highest trees, the assembled multitude, at the signal note of their leader, wing their way to the opposite shore. The old and fat birds, contrary to what might be expected, cross without difficulty even when the river is a mile in width; but the wings of the young and meagre, and of course those of the weak, frequently fail them before they have completed their passage, when in they drop, and are forced to swim for their lives, which they do cleverly enough, spreading their tails for a support, closing their wings, stretching out their neck, and striking out quickly and strongly with their feet. All do not succeed in such attempts, and the weaker often perish.

The wild turkeys, according to the same interesting author, feed on maize, all sorts of berries, fruits, grasses, and testæ; tadpoles, young frogs, and lizards are occasionally found in their crops. The pecan-nut is a favourite food, and so is the acorn, on which last they fatten rapidly. About the beginning of October, whilst the mast still hangs on the trees, they gather together in flocks, directing their course to the rich bottom lands, and are then seen in great numbers on the Ohio and Mississippi. This is the *turkey-month* of the Indians. When the turkeys have arrived at the land of abundance, they disperse in small promiscuous flocks of every sex and age, devouring all the mast as they advance. Thus they pass the autumn and winter, becoming comparatively familiar after their journeys, and then venturing near plantations and farm-houses. They have been known on these occasions to enter stables and corn-cribs in search of food. Numbers are killed in the winter, and are preserved in a frozen state for distant markets. The beginning of March is the pairing time, for a short time previous to which the females separate from their mates, and shun them, though the latter pertinaciously follow them, gobbling loudly. 'The sexes,' continues the Prince, 'roost apart, but at no great distance, so that when the female utters a call, every male within hearing responds, rolling note after note in the most rapid succession; not as when spreading the tail and strutting near the hen, but in a voice resembling that of the tame turkey when he hears any unusual or frequently repeated noise. Where the turkeys are numerous, the woods, from one end to the other, sometimes for hundreds of miles, resound with this remarkable voice of their wooing, uttered responsively from their roosting places. This is continued for about an hour; and, on the rising of the sun, they silently descend from their perches, and the males begin to strut for the purpose of winning the admiration of their mates. If the call be given from the ground, the males in the vicinity fly towards the individual, and, whether they perceive her or not, erect and spread their tails, throw the head backwards, distend the comb and wattles, strut pompously, and rustle their wings and body-feathers, at the same moment ejecting a puff of air from the lungs. Whilst thus occupied, they occasionally halt to look out for the female, and then resume their strutting and puffing, moving with as much rapidity as the nature of their gait will admit. During this ceremonious approach, the males often encounter each other, and desperate battles ensue, when the conflict is only terminated by the flight or death of the vanquished.' The usual fruits of such victories are reaped by the conqueror, who is followed by one or more females, which roost near him, if not upon the same tree, until they begin to lay, when their habits are altered with the view of saving their eggs, which the male breaks if he can get at them. They are usually from nine to fifteen in number, sometimes twenty, whitish and spotted with brown like those of the domestic bird. The nest consists of a few dried leaves placed on the ground, sometimes on a dry ridge, sometimes in the fallen top of a dead leafy tree, under a thicket of shumach or briars, or by the side of a log.

Mr. Audubon gives a graphic picture of the parental care of the female; and to his interesting work we must refer the reader for this and other accounts of the habits of these birds, and the enemies with which they have to cope. Bartram also has some curious anecdotes on this part of the subject.

This is the *Meleagris occidentalis* of Bartram; *Meleagris fera* of Vieillot; *Gallo d'India*, *Gallinaccio* (male), *Gallina d'India* (female), of the Italians; *Coq d'Inde* and *Dindon*, *Dinde* (female), of the French; *Indianische Hahn* of the Germans; *Wild Turkey* and *Domestic Turkey* of the British and Anglo-Americans.

Geographical Distribution.—The range of the wild turkey appears to extend from the north-western territory of the United States to the Isthmus of Darien: the birds which have been taken for it to the south of the Isthmus were probably Curassows [CRACIDÆ]; and the improbability of its extension beyond the Rocky Mountains, or even so far, is shown not only by the absence of notice of it by the travellers in those parts, but from more positive evidence. The Prince of Musignano relates that when the Mandan Indians visited the city of Washington, not many years ago, they looked upon the turkey as a great curiosity, and prepared the skin of one to carry home for exhibition. The wooded tracts of Arkansas, Louisiana, Tenessee, and Alabama, and the unsettled parts of the states of Ohio, Kentucky, Indiana, and Illinois, form the great nursery of this species; but their domain is daily shrinking before the activity of the settler; and many years will not elapse before the turkey will cease to exist as a wild species. It however still occurs, though probably in no great numbers, in the mountainous parts of the United States, for instance, in the Blue Ridge in Virginia. Fortunate it is that the race has been secured to man in a state of domestication.

Belon was one of the first who considered the bird to be the *Meleagris* of the antients; and this is somewhat extraordinary, because he appears to have been a good scholar, and the bulk of the passages in which the *Meleagris* is mentioned show that it could not have been a turkey. Aldrovandus, Gesner, and others followed in the wake of Belon. Linnæus, though he retains the name *Meleagris*, well knew that the turkey was a native of the new world; for he places its 'habitat' 'in America Septentrionali;' he also knew that it was the parent stock of the domesticated turkey; for he gives short but very good directions for the care of the young, and mentions their favourite food: 'Pulli delectantur Allio, Urtica; a fame et pluvia cavendi.' In well-regulated poultry-yards, curd, chopped onions (the green part), and boiled nettles are among the best kinds of food now in use for turkey chicks, whose very existence depends upon regular feeding and protection from rain. Barrington (1781) is the last writer of any note who supported the theory that the turkey was the *Meleagris* of the antients: it is however but right to remark that, when he wrote, the existence of the large flocks in a wild state in North America was not generally known, though many of the older writers (Lawson and others, for instance) mention them. Pennant in a masterly manner overthrows that theory, upon which we shall not longer detain the reader, the question being now considered as settled.*

The time of the first appearance of the turkey in Europe is more doubtful. The French writers attribute its introduction to the Jesuits somewhat hastily, for there is evidence that turkeys were known in Europe about 1530, if not before that year; whereas it was not before 1534 that Ignatius Loyola, being at Paris, entered into a solemn compact with six of his friends and fellow-students to promote his great object, the foundation of that religious order. [JESUITS.] The probability is that the Spaniards were the first to bring this bird to Europe, whence it has spread over the whole civilised world; but it is not impossible that it may have been brought to England by Cabot, or some of the subsequent expeditions.

In a domesticated state the plumage varies as much or more than it does in the common poultry. White is far from uncommon; buff is more rare. But the most curious variety is that mentioned by M. Temminck, which was in Madame Backer's aviary at the Hague. This bird has a topknot springing from the crown of the head; and a flock of a pale reddish tint, with an ample crest of pure white, were reared by the same lady.

The royal forests of this country would afford ample shelter to these fine birds, and there, with little trouble, they might be kept in a state of nature. They would soon return to their wild habits, even if it should be thought too much trouble to import some of the true wild breed; and a noble addition they would make to the game in such royal preserves as Windsor and the New Forest. Formerly many were thus kept in Richmond Park, and Windsor Forest was much frequented by them.

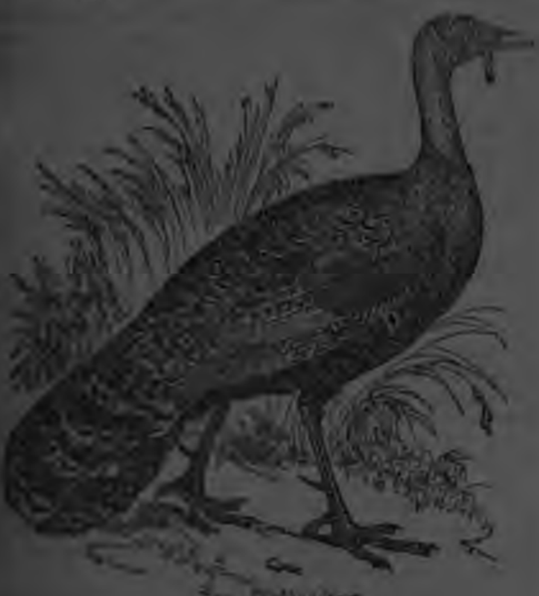
Meleagris ocellata.—Cuvier first described this beautiful bird from the specimen formerly in Mr. Bullock's museum, and now in that of Paris, for which it was bought at the breaking up of Mr. Bullock's collection, and lost to this country.

The crew of a vessel were cutting wood in the Bay of Honduras, when they saw three individuals, and captured one alive, which was sent to Sir H. Halford, and met with an accident after its arrival in the Thames, and before it reached Sir Henry, which caused its death. Sir Henry presented it to Mr. Bullock, who then exhibited his museum in the Egyptian Hall, Piccadilly, of which it was one of the most distinguished ornaments.

Description.—Size nearly that of the common Turkey, but the tail is not so much developed, nor is it known whether the bird can spread it or not: the probability is that it can. Bill of the same form with that of the com-like turkey, having a caruncle at its base, apparently capable of elongation and contraction like that of the common sort. Head and two-thirds of the neck naked, and, apparently, livid, but without fleshy tubercles on the lower part. There are five or six above each eye, five upon the centre of the crown, and six or seven in a line one above the other at nearly equal distances on the sides of the neck. No trace of a tuft on the breast could be perceived; but the plumage was rather damaged. Feathers rounded at the ends; those of the lower part of the neck, upper part of the back, scapulars, and all the lower part of the body, bronze-green, with two terminal bands, the first black, and the last, or that next to the tip, of a golden bronze hue. The bands on the other parts of the back are the same, but near the tail-coverts they are more vivid, the bronze becoming of a rich blue or emerald green, according to the incidence of the light, whilst the outer band becomes broader and more golden. Red mingles with the tints on the rump, where the plumage almost assumes the brilliant character of that of some Humming-birds, and the bright border is separated from the blue by a band of velvety black. The hidden part of each feather is grey, mottled with black, and indeed upon the tail and upper coverts this grey is drawn, forming bars, one of which, immediately succeeding the blue band, surrounds it, and gives each feather an ocellated appearance. The tail-coverts and lower feathers of the rump are so disposed that there are four rows with these ocellated tips. The tail, consisting of fourteen feathers only, is rounded. Lower parts of the body banded with bronze, black and green, but wanting the lustre of the upper parts. Quills and bastard wing black, edged obliquely with white, which occupies the external margin of the first almost entirely. Outer webs of the secondaries pure white, not showing the bands in the centre when the wings are closed; the uppermost blotched in the centre with black shot with green, which as the feathers shorten extends more over their surface, so as to leave only a white edge. Greater coverts chesnut. Feet and legs lake-red. (Cuvier; Temminck.)

---

* M. Temminck, in the 4th part of his 'Manuel' just published (1840), quotes M. Cantraine, who states that the inhabitants of Sicily and Dalmatia assert that wild turkeys have been killed in those countries. M. Temminck considers these statements as very doubtful; but allowing them to be true, there would be nothing to prove that the birds alluded to had not escaped from the dominion of man and become wild.



Meleagris ocellata.

Polyplectron. (Temm.)

Generic Character.—*Bill* moderate, slender, straight, compressed, the base covered with feathers, convex above, where it is rather thick; orbits and part of the cheeks naked; *nostrils* lateral, placed towards the middle of the bill, and half closed by a membrane. *Two spurs* on the *tarsi*; *tarsi* long and slender, the hind toe not touching the ground. *Tail* feathers long and rounded, the fifth and sixth longest.

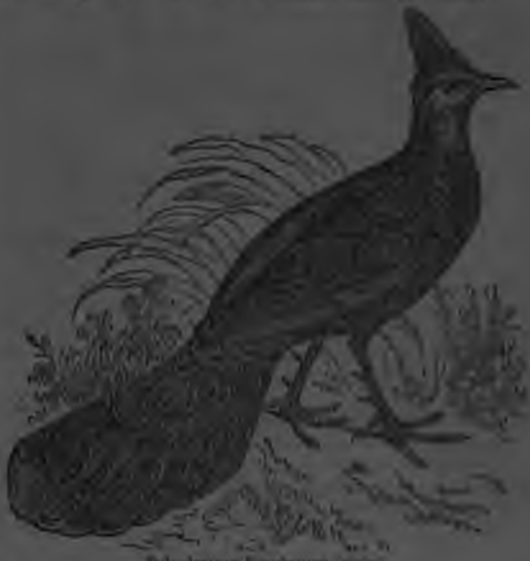
This beautiful form was raised to the rank of a genus by M. Temminck, who established it upon the bird which was named *Pavo Thibetanus* by Brisson, *The Chinese Peacock Pheasant* by Edwards, *Pavo bicalcaratus* by Linnæus, and *L'Eperonnier* by Buffon. Cuvier placed it among the Pavonidæ, properly so called, but other species have been since discovered, which, throwing further light upon the modifications of form, well justify its generic separation. It is the *Diplectron* of Vieillot.

Examples.—*Polyplectron Emphanum*; *Polyplectron Chinquis*; *Polyplectron Chalcurum*.

Polyplectron Emphanum.

Description.—*Male*: Length about 19 inches. Forehead and crown ornamented with a crest of long, narrow, loose feathers, which, together with the plumage of the neck and breast, are rich bluish black with metallic reflections. Above the eyes a large pure white shining stripe, and a patch of the same colour upon the ear-feathers. Back and rump brown, with irregular paler waved bands. Belly and vent deep black. Wing-coverts and secondaries brilliant blue, each feather tipped with velvety black. Tail rather long, much rounded, brown thickly spotted with ochraceous white, and distinguished by large ocellated oval spots of a brilliant metallic green. Towards the end of each feather there is a blackish bar. This beautiful and ample tail is supposed not to be erectile, but to be capable of very wide expansion. This is the *Eperonnier à Toupet* of M. Temminck; *the Crested Polyplectron*.

Locality.—Sunda and the Molucca Isles probably.



Polyplectron Emphanum (male).

Polyplectron Tibetanum.

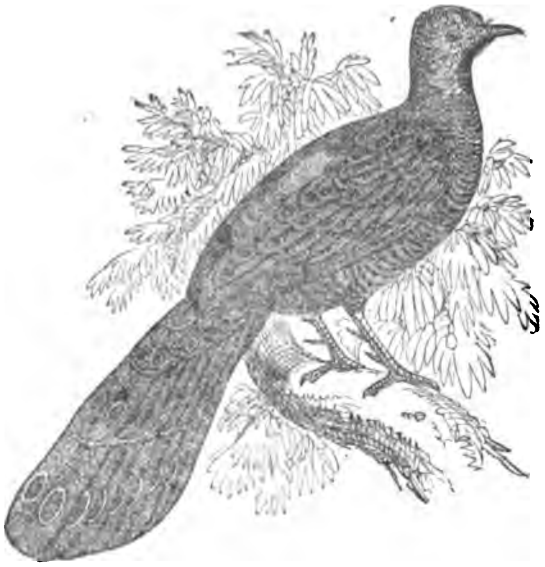
Description.—*Male*: Length about 22 inches. No crest, but the small greyish-brown plumes on the crown of the head are turned forwards, and appear as if ruffled. Head, neck, breast, and belly brown, with transverse waved bands of blackish brown. Throat whitish. Back, rump, and tail-coverts clear brown, spotted and waved transversely with greyish white. Quills brown, marked with greyish; wings, generally, yellowish grey sprinkled with small blackish-brown bands, each feather having at its extremity a large round ocellated brilliant blue spot shot with purple and opaline hues. A circle of deep black, which is, in its turn, set in a ring of yellowish white, surrounds each of these iridescent spots. Tail-feathers dull brown, sprinkled with small ochraceous spots. Upon each of the twenty-two true tail-feathers, at about an inch and a half from the tip, as well as on those of what has been called the upper range at about an inch from the tip, two oval spots with purple and blue reflections with double circles of black and white like those of the wing, but hardly so brilliant, are separated by the shaft only.

Female.—Differing from the male in having the ocellated spots less brilliant, a shorter tail, and no spurs.

Young.—Plumage earthy grey, with large brown spots and bands. At the first moult the plumage becomes more irregular, the spaces upon the wings and tail where the spots are to appear become visible, but they are without lustre, and the pale circle is not present. At the third moult the plumage acquires its full brilliancy. (Temminck, &c.)

This is the *Pavo Tibetanus* of Brisson and Gmelin, the *Chinquis* of Buffon, the *Thibet Peacock* of Latham, the *Peacock Pheasant* of Edwards, and the *Eperonnier Chinquis*, *Polyplectron Chinquis* of Temminck.

Locality.—Supposed to be the mountain-chain which separates Hindustan from Thibet



Thibetian Polyplectron.

In the *Polyplectron Chalcurum* the plumage is comparatively sombre. The ocellated spots on the wings and tail are absent, and the latter, instead of being rounded, has a more elongated pheasant-like form, approaching to that of *Argus.*

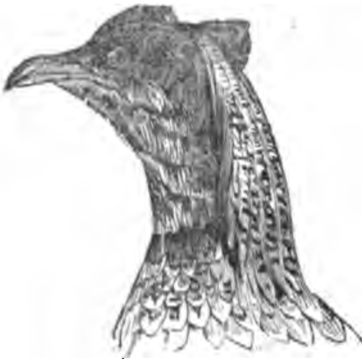
The beautiful birds above briefly noticed, and inhabiting the Indian Islands or China, are described as being almost as hardy as the peacock, and there is little doubt that they might be domesticated in this country. The *Thibetian Polyplectron* is procured for the aviaries of the wealthy Chinese, and M. Temminck's drawing was taken from a bird that had lived for five or six years in an aviary at the Hague.

Mr. Gray (*Illustrations of Indian Zoology*) has figured two other species, *Polyplectron Hardwickii*, nearly allied to *P. bicalcaratum* and *P. lineatum*, which appears to Sir W. Jardine to be the young of some other species; there are, he observes, no spurs on the tarsi. Mr. Gray's figures were taken from General Hardwicke's drawings by native artists.

Argus. (Temm.)

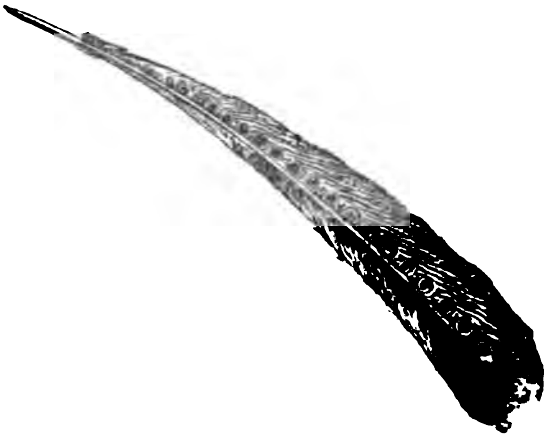
Generic Character.—*Bill* compressed, straight except at the extremity, where it is curved, vaulted, and naked at its base; *nostrils* placed in the middle of the upper mandible, half-closed; head, cheeks, and neck naked. *Tarsi* long, slender, spurless. Two middle *tail*-feathers longest, *secondary quills* much more developed than the primaries.

Example.—The only species known is *Argus giganteus.*



Head of Argus.

Description.—*Adult Male:* In bulk not exceeding an ordinary fowl, but measuring from the tip of the bill to the extremity of the two long tail-feathers five feet three inches, of which length those feathers form three feet eight inches. Throat, upper part of the neck, and cheeks naked or nearly so, there being only a few black hairs dispersed over them. Feathers of the head and back of the neck short and velvety Lower part of the neck, breast, belly, and thighs reddish brown, each feather speckled with dull yellow and black. Upper part of the back and lesser wing-coverts covered with large black spots, separated by a narrow ochraceous line; upper tail coverts clear ochraceous yellow, with brown spots; the longest paler, with spots thicker than on the back, and reddish brown in the centre. Tail deep chesnut sprinkled with white spots, which are encircled with a black ring. The wings, the secondaries of which are three times as long as the primary quills, are painted and ocellated in a manner that defies description. A very faint idea of the pattern of one of these secondaries may be derived from the accompanying cut.



Secondary quil. of Argus giganteus.

Young Males.—Uniform dull brown, spotted and irregularly blotched with reddish yellow, brown, and black. No appearance of the ocellated spots after the first moult and before the second. The shafts of the wing-feathers are black, the quills dull brown, clouded with a line on the inner webs, but the outer show black undulated bands on a brownish yellow ground, and the parts where the ocellated spots are to come are marked with black crescents surrounded with chesnut. After the second moult all the colours are more regularly distributed. After the third their definition is still more exact, but the showy spots are small, irregular in form, and less numerous than in full-grown birds. After the fourth moult the colours acquire their beautiful and elegant harmony, and the markings and spots their full size and complete regularity.

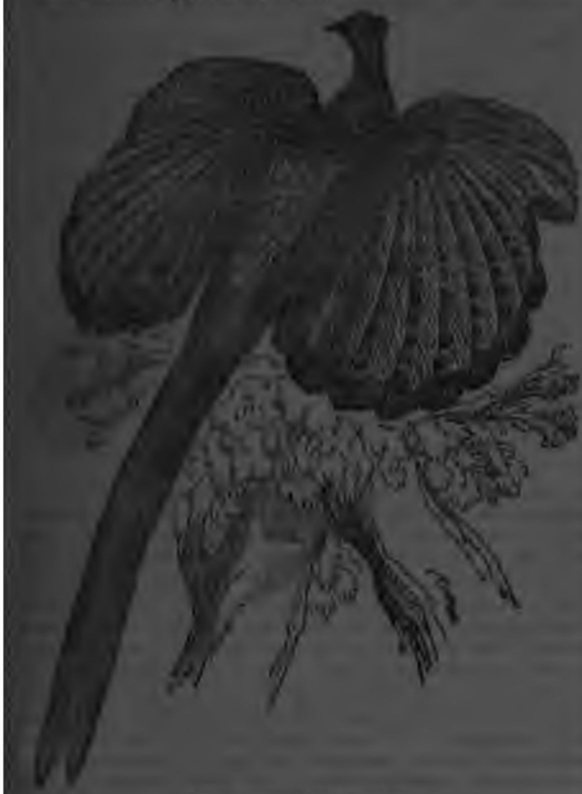
Females.—Head and fore-part of the neck naked; the top of the head is covered with a thick short down, which stretches downwards upon the neck, where it becomes gradually longer, and assumes the form of feathers. The other parts are brownish grey. Lower portion of the neck, breast, and upper parts of the back, chesnut-red; lower part of back, rump, lesser wing-coverts, and tail-coverts have numerous black bands on a yellowish-brown ground. Some of these bands are large, and others narrow and zigzag. No long feathers in the tail, which folds together, forming an angle like that of a common hen, and is brownish chesnut variegated with spots and black bands. The secondaries, which in the male are two feet ten inches in length, are in the female only thirteen inches, narrow, and, with the ocellated spots much less conspicuous, blackish-brown, with small and irregular bands of ochraceous yellow.

This is the *Beautiful Chinese Pheasant* described 'Phil. Trans.,' vol. 55, p. 88; *L'Argus* ou *Luen* of Buffon; *Argus Pheasant*, *Phasianus Argus* of Latham: *L'Argus*, *Argus giganteus* of Temminck.

M. Temminck, from whom the above descriptions are taken, only obtained two females with thirty males. This was most probably owing to the males being the great object of the hunters from their magnificent plumage.

Habits.—The unwieldy size of the secondaries forms an impediment to the bird in its progress through the air, but they assist its pace when running, which it does swiftly with their aid. Its flight, when it does rise on the wing, is heavy and short. When the bird is at rest or unexcited, the beautiful spots on the secondaries are hardly visible; but when showing himself off in the presence of his females, the wings of the Argus are expanded, and trailed upon the ground to display their beauties; and at this time the tail is comparafully spread, and is raised erect; when at rest it is carried in a line with the body, and with the two long feathers folded together. The rest of its habits are not known, but it is said not to thrive well in confinement.

Locality.—Sumatra, and probably other Indian Islands, but principally of Malacca. No proof appears of its having been brought from China and Chinese Tartary, although ornithological writers name those countries as the places of its habitation: the feathers and drawing of the bird described in 'Phil. Trans.' by G. Edwards were sent from Canton to Dr. Fothergill, and are stated to have come from one of the most northern provinces of China.



Argus giganteus; full-grown male.

Lophophorus. (Temm. Monaulus, Vieill.)

Generic Character.—*Bill* strong, long, very much curved, wide at its base, rather thick, convex above, the upper mandible longer than the lower, and overlapping it, large and trenchant at its extremity; *nostrils* half closed by a membrane covered with small scattered plumes. *Tarsus* furnished with a long and sharp spur; hind toe elevated and not touching the ground except at its end. *Tail feathers* fourteen, straight and rounded. Fourth and fifth *quills* longest.

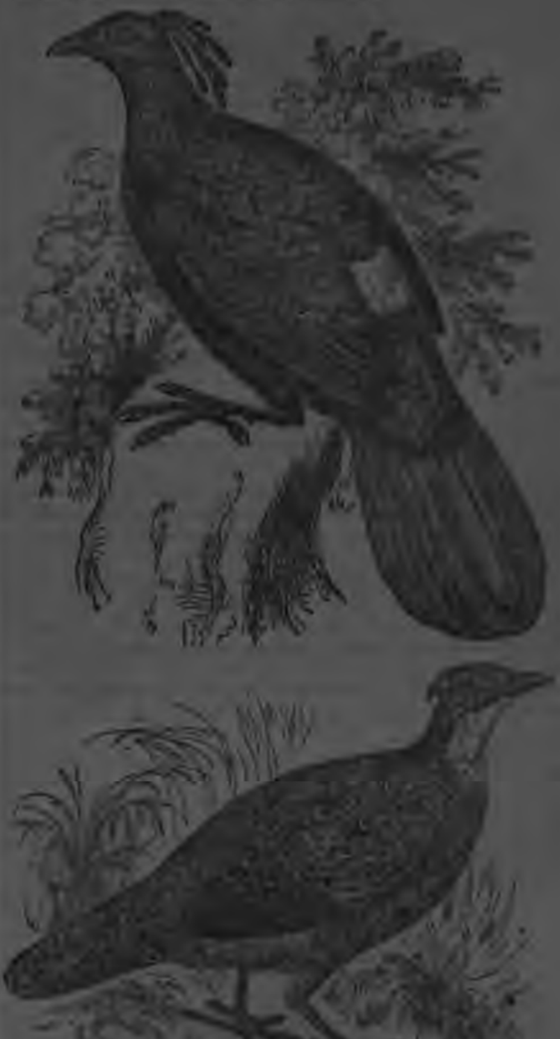
Example, Lophophorus Impeyanus.

Head of Lophophorus Impeyanus. Male.

Description.—*Male*: We must refer our readers to the coloured plates or to the excellent figure in Mr. Gould's *Century of Birds from the Himalaya Mountains*, for anything like an adequate idea of the beauty of its tints; for the greater proportion of the plumage is dazzling with changing hues of green, steel-blue, violet, and golden bronze. The bird looks as if it were principally clothed in a scale-armour of iridescent metal; but the plumage is soft and velvety to the touch. The crest on the head consists of naked-shafted feathers, with an oval or battledore tip of the same quality as the rest of the plumage, and of a metallic green. The centre of the back is pure white. The tail is rounded and bright chesnut. Size of a hen turkey.

Female.—Much smaller. Her plumage is altogether sombre, and without a trace of the splendour which shines forth in the male. The feathers of the head are a little lengthened behind, but not in any degree like the crest of the male. Fore-part of the neck pure white; rest of the plumage reddish-brown variegated and mottled with spots and bars, except a little white at the extremity of the tail-coverts and tips of the tail-feathers.

Young Male.—Much like the female.



Lophophorus Impeyanus, male and female; upper figure, male. (Gould.)

Habits, Food, &c.—The principal food of this species consists of bulbous roots, for scooping out which its bill is well adapted. Nothing certain seems to be known of the rest of its habits.

Locality.—The mountain-ranges of Nepaul and Himalaya. This is the *Lophophorus refulgens* of Temminck; *Impeyan Pheasant, Phasianus Impeyanus* of Latham.

There is little doubt that this noble bird would bear the climate of Great Britain, or that it might be made a splendid addition to our game preserves.

Numida. (Linn.)

Generic Character.—*Bill* short, strong, vaulted, stout, furnished with a warty membrane at the base; from the lower mandible hang two carunculated wattles; head naked or feathered; forehead surmounted with a bony casque or feathered crest; *nostrils* pierced in the cere, and divided by a cartilage. *Tail* short. Fourth *quill* longest.

The birds known to the antients under the name of *Meleagrides*[*] and *Gallinæ Numidicæ* belonged to this genus. They are all natives of Africa, living principally on berries, small slugs, &c. We select as examples *Numida Meleagris* and *Numida cristata*.

Numida Meleagris.—This, the *Gallina di Numidia* of the Italians, *Poulle de la Guinée* and *Peintade Meleagride* of the French, *Pintado* of the Spanish, *Perl Huhn* of the Germans, and *Pearl Hen*, *Guinea Hen*, and common *Guinea Fowl* of the British, is too well known to need description.

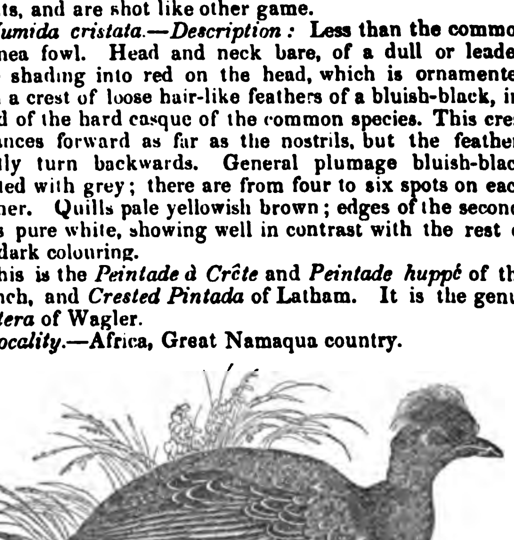
Head of Numida Meleagris.

The bird has been spread very widely, and few poultry yards are without it. In Jamaica, where they do much mischief to some of the crops, they have resumed their wild habits, and are shot like other game.

Numida cristata.—*Description:* Less than the common Guinea fowl. Head and neck bare, of a dull or leaden blue shading into red on the head, which is ornamented with a crest of loose hair-like feathers of a bluish-black, instead of the hard casque of the common species. This crest advances forward as far as the nostrils, but the feathers mostly turn backwards. General plumage bluish-black spotted with grey; there are from four to six spots on each feather. Quills pale yellowish brown; edges of the secondaries pure white, showing well in contrast with the rest of the dark colouring.

This is the *Peintade à Crête* and *Peintade huppé* of the French, and *Crested Pintada* of Latham. It is the genus *Guttera* of Wagler.

Locality.—Africa, Great Namaqua country.



Numida cristata.

Mr. Swainson is of opinion that the *Spotted-winged Pintado* is a distinct species, which he names *Numida maculipennis*.

PAWN. [PLEDGE.]

PAWNBROKERS. All persons who receive goods by way of pawn or pledge for the repayment of money lent thereon at a higher rate of interest than five per cent. per annum, are pawnbrokers. The character of the individual to whom the money is lent is scarcely a subject of consideration with the lender; he may be satisfied, if he believe that the articles pledged are not stolen or come by in an unlawful manner.

Pawning differs from other ways of lending and borrowing money in this: in pawning, the goods of the borrower are delivered to the lender as a security. [PLEDGE.] When the lender has confidence in the integrity and solvency of the borrower, he is often satisfied with a written engagement from the borrower, and if it should be required, with the additional engagement of some other person. When further security is required by the lender, it may be land, or shares in a ship, or it may be something which is not in its nature capable of immediate tradition, as the future benefit to accrue from a policy of insurance; but all these kinds of security are different from that given in pawning, and are treated under the articles MORTGAGE and SHIPS.

The business of lending money on pledges is in many countries carried on under the immediate control of the government as a branch of the public administration; and where only private individuals engage in it, as in this country, it is placed under regulations. Thus in China, where pawnbrokers are very numerous, Mr. Davis says (*Chinese*, vol. ii., p. 438), 'they are under strict regulations, and any one acting without a licence is liable to severe punishment. The usual period allowed for the redemption of the pawned goods is three years. The highest legal rate of interest on deposits is three per cent. per month; but in the winter months the money advanced on wearing apparel may not exceed two per cent., on the alleged ground that poor persons may be able the more easily to redeem.'

The 12 Anne, stat. 2, c. 16, fixes the legal rate of interest at 5 per cent. per annum; but the interest which pawnbrokers are allowed to charge is regulated by a special statute, the 39 and 40 George III., c. 99, passed 28th of July, 1800. This Act fixes the rates of interest allowed on goods or chattels placed in the hands of pawnbrokers according to the following scale:—

For every pledge upon which there shall have been lent any sum not exceeding 2*s*. 6*d*., the sum of ½*d*., for any time during which the said pledge shall remain in pawn not exceeding one calendar month, and the same for every calendar month afterwards, including the current month in which such pledge shall be redeemed, although such month shall not be expired. If there shall have been lent the sum of 5*s*., one penny; 7*s*. 6*d*., one penny halfpenny; 10*s*., two-pence; 12*s*. 6*d*., two-pence halfpenny; 15*s*., three-pence; 17*s*. 6*d*., three-pence halfpenny; 20*s*., four-pence; and so on progressively and in proportion for any sum not exceeding forty shillings; but if exceeding 40*s*. and not exceeding 42*s*., eight-pence; if exceeding 42*s*., and not exceeding 10*l*., after the rate of three-pence for every 20*s*., by the calendar month, including the current month, and so on in proportion for any fractional sum. Parties may redeem goods within seven days after the expiration of the first calendar month without paying interest for the extra seven days; or within fourteen days on paying for one month and a half; after which time interest is charged for two calendar months.

Pawnbrokers are required by the Act to keep books in which all goods taken in pledge must be entered and described, the sum advanced upon them, and the name and abode of the pledger, and whether he is a housekeeper or a lodger. They make out at the time two memoranda of these particulars, one of which is given to the pledger. This duplicate is given gratis in all cases where the sum advanced is under 5*s*.; when it is 5*s*. and under 10*s*., one halfpenny is charged; 10*s*. and under 20*s*., one penny; 20*s*. and under 5*l*., twopence; 5*l*. and upwards, fourpence. Articles pledged for sums above 5*s*. must be entered in the pawnbroker's books within four hours; and those on which 10*s*. or upwards have been advanced must be entered in a separate book and numbered, the first entry in each month commencing No. 1. The number and description of the pledge in the books and on the duplicate correspond with each other. Articles cannot be taken out of pawn without the production of the duplicate, the holder of which is assumed to be the owner. If a duplicate should be lost or stolen, the pawnbroker is required to give a copy of it to the party representing himself as the owner of the article pledged, with a blank form of affidavit, which must be filled up with a statement of the circumstances under which the original duplicate was lost, to the truth of which depothat on oath must be made before a magistrate. For this second duplicate the pawnbroker is entitled to demand one halfpenny, if the sum advanced does not exceed 5s.; from 5s. to 10s., one penny; and afterwards in the same proportion as for the original duplicate.

---

[*] Brisson retains the antient appellation for this genus, which stands in his system as *Meleagris*; but the word is so universally used by ornithologists as the generic name for the Turkeys, that it would be productive of confusion to apply it to the Guinea-fowls.

The penalty against unlawfully pawning goods the property of others is between 20s. and 5l., besides the full value of the goods pledged; and in default of payment, the offending party may be committed for three months' imprisonment and hard labour. Persons forging or counterfeiting duplicates, or not being able to give a good account of themselves on offering to pawn goods, are liable to imprisonment for any period not exceeding three months. Pawnbrokers or other persons buying or taking in pledge unfinished goods, linen or apparel entrusted to others to wash or mend, are to forfeit double the sum advanced and to restore the goods. The Act empowers police-officers to search pawnbrokers' houses or warehouses when suspected to contain unfinished goods unlawfully pledged, and goods unlawfully pawned must be restored to the owner by the pawnbroker.

All pawned goods are deemed forfeited at the end of one year. If redeemed, the pawnbroker must endorse on his duplicate the charge for interest, and keep it in his possession for one year. Articles on which sums have been advanced of 10s. and not exceeding 10l., if not redeemed, must be sold by auction, after being exposed to public view and at least two days' notice having been given of the sale. The catalogue of sale must contain the name and abode of the pawnbroker, the month the goods were received, and their number as entered in the books and on the duplicate. Pictures, prints, books, bronzes, statues, busts, carvings in ivory and marble, cameos, intaglios, musical, mathematical, and philosophical instruments, and china, must be sold separate from other goods, on the first Monday in January, April, July, and October in every year. On notice not to sell given in writing, or in the presence of one witness, from persons having goods in pledge, three months further are allowed beyond the year for redemption. An account of sales of pledges above 10s. must be entered in a book kept by the pawnbroker, and if articles are sold for more than the sum for which they were pledged, with interest thereon, the owner is entitled to the overplus, if demanded within three years after the sale. Pawnbrokers' sale books are open to inspection on payment of a fee of one penny. The penalty on pawnbrokers' selling goods before the proper time, or injuring or losing them, and not making compensation to the owner, according to the award of a magistrate, is 10l. They are required to produce their books on the order of a magistrate in any dispute concerning pledges, and are not to purchase goods which are in their custody. The Act extends to the executors of pawnbrokers.

The Act prohibits pledges being taken from persons intoxicated or under twelve years of age. (By the 'Metropolitan Police Act' (2 & 3 Vic., c. 47), a fine of 5l. is inflicted upon pawnbrokers taking pledges from persons under the age of sixteen.) Pawnbrokers are prohibited from buying goods between the hours of 8 A.M. and 7 P.M.; or receiving pledges from Michaelmas-day to Lady-day before 8 A.M. or after 8 P.M.; or for the other part of the year, before 7 A.M. or after 9 P.M., excepting on Saturdays and the evenings preceding Good Friday and Christmas Day, when the hour for closing is extended to 11 P.M. They are required to place a table of profits and charges in a conspicuous part of their place of business.

Pawnbrokers are required to take out an annual licence from the Stamp-Office; and, to enable them to take in pledge articles of gold and silver, a second licence is necessary, which costs 5l. 15s. Those who carry on business within the limits of the old Twopenny Post pay 15l. a year for their licence, and in other parts of Great Britain 7l. 10s. The licence expires on the 31st July, and a penalty of 50l. is incurred if it is not renewed ten days before. No licence is required in Ireland, but those who carry on the business of a pawnbroker must be registered.

From 1833 to the end of 1839, the number of pawnbrokers in the metropolitan district increased from 368 to 386; in the rest of England and Wales, from 1032 to 1194; and in Scotland, from 52 to 88: making a total of 1668 establishments, which pay 15,415l. for their licences, besides the licence which many of them take out as dealers in gold and silver. The increase in the number of pawnbrokers in the course of the above five years is nearly 5 per cent. in London, 15 per cent. for other parts of England and Wales, and nearly 70 per cent. for Scotland. The increase in England is to a considerable extent chiefly in places where the business of a pawnbroker has not hitherto been carried on; and in Scotland, according to the 'New Statistical Account' now publishing, the extent of this innovation is quite remarkable. The business of a pawnbroker was not known in Glasgow until August, 1806, when an itinerant English pawnbroker commenced business in a single room, but decamped at the end of six months; and his place was not supplied until June, 1813, when the first regular office was established in the west of Scotland for receiving goods in pawn. Other individuals soon entered into the business, and the practice of pawning had become so common, that, in 1820, in a season of distress, 2043 heads of families pawned 7380 articles, on which they raised 738l. 5s. 6d. Of these heads of families 1375 had never applied for or received charity of any description; 474 received occasional aid from the Relief Committee; and 194 were paupers. The capital invested in this business in 1840 is about 26,000l. Nine-tenths of the articles pledged are redeemed within the legal period. (Dr. Cleland's 'Former and Present State of Glasgow,' 1840.) There are no means of ascertaining the exact number of pawnbrokers' establishments in the large towns of England. In 1831 the number of males above the age of twenty employed in those at Manchester was 107; at Liverpool, 91; Birmingham, 34; Bristol, 23; Sheffield, 21; but owing to the time which has elapsed since the census and the kind of information which it gives on this matter, we are without such knowledge on this subject as it would be desirable to possess. A return of the amount and nature of the dealings of pawnbrokers would doubtless offer many valuable illustrations of the condition and habits of the people. The only return of the kind which we have seen, was supplied by a large pawnbroking establishment at Glasgow to Dr. Cleland, who read it at the meeting of the British Association for the Advancement of Science in 1836. The list comprised the following articles:—539 men's coats, 355 vests, 288 pairs of trowsers, 84 pairs of stockings, 1980 women's gowns, 540 petticoats, 132 wrappers, 123 duffles, 90 pelisses, 240 silk handkerchiefs, 294 shirts and shifts, 60 hats, 84 bed-ticks, 108 pillows, 252 pairs of blankets, 300 pairs of sheets, 162 bed-covers, 36 table-cloths, 48 umbrellas, 102 Bibles, 204 watches, 216 rings, and 48 Waterloo medals. It was not stated during what period these articles were received. There are in Glasgow above thirty pawnbrokers. In the manufacturing districts during the prevalence of 'strikes,' or in seasons of commercial embarrassment, many hundreds of families pawn the greater part of their wearing-apparel and household furniture. (Paper read in 1837 by Mr. Ashworth, of Bolton, 'On the Preston Strike in 1836.') The borough-reeve of Manchester stated on a recent occasion (April, 1840) that a clergyman had shown him sixty-seven pawn-tickets from one family, and he said there were thousands in similar circumstances 'going inch by inch,' in consequence of the stagnation of industry. The practice of having recourse to the pawnbrokers on such occasions is quite of a different character from the habits of dependence into which many of the working classes suffer themselves to fall, and who, 'on being paid their wages on the Saturday, are in the habit of taking their holiday clothes out of the hands of the pawnbroker to enable them to appear respectably on the Sabbath, and on the Monday following they are again pawned, and a fresh loan obtained to meet the exigencies of their families for the remainder of the week.' (Petition 1131, *Appendix to the 42nd Report on Public Petitions, Session 1839.*) It is on these transactions and on such as arise out of the desire of obtaining some momentary gratification that the pawnbrokers make their large profits. It is stated in one of the Reports on the Poor-Laws that a loan of

3d., if redeemed the same day, pays annual interest at the rate of 5200 per cent.; weekly, 866 per cent.

4d.	„	3900	„	„	650	„
6d.	„	2600	„	„	433	„
9d.	„	1733	„	„	288	„
12d.	„	1300	„	„	216	„

In the petition already quoted, it is stated, that on a capital of 6d. thus employed (in weekly loans) pawnbrokers make in twelve months 2s. 2d.; on 5s. they gain 10s. 4d.; on 10s. they clear 22s. 3½d.; and on 20s., lent in weekly loans of sixpence, they more than double their capital in twenty-seven weeks; and should the goods pawned remain in their hands for the term of twelve months (which seldom occurs), they then derive from 20 to 100 per cent. The 'Loan Fund Societies,' which are protected by an Act of the Legislature, and advance small sums under 15*l.* at 5 per cent., are of no advantage to the habitual dependants upon the pawnbroker.

The 'Pawnbrokers' Gazette' is a stamped weekly publication containing advertisements of sales, and other information of use to the trade, amongst whom it exclusively circulates.

The act for the regulation of pawnbrokers in Ireland is the 28 George III., c. 43 (Irish statute). It requires pawnbrokers to take out licences and to give securities; appoints the marshal of the city of Dublin corporation registrar of licences; directs returns to be made to him monthly, upon oath, of sums lent; and allows the registrar a fee of one shilling on each return. The act requires the returns to be laid before parliament; but this is not done, and a petition was presented to the House of Commons, in 1837, complaining that the statute was evaded by an arrangement made by the registrar with the pawnbrokers not to require any returns from them, upon their paying him 1*l.* yearly. The act is also neglected in other respects, especially in the mode of selling unredeemed pledges. The rate of interest allowed is 25 per cent. per annum. Duplicates are charged one penny for sums under 10*s*; from 10*s*. to 40*s*., twopence; from 40*s*. to 10*l*., fourpence. It is the practice to charge interest for one whole month, though in a great number of cases the article pledged is redeemed in a week. The operation of this plan is shown in the following table:—

	Per week.			Per month.			Per year.		
	£.	*s.*	*d.*	£.	*s.*	*d.*	£.	*s.*	*d.*
One shilling per week, ½*d.* interest, and 1*d.* for the duplicate, is	0	0	1½	0	0	6	0	6	6
One pound lent in shillings pays 10*d.* interest, and 1*s.* 8*d.* for duplicates, is . . .	0	2	6	0	10	0	6	10	0
One hundred pounds lent in shillings pays 4*l.* 3*s.* 4*d.* interest, and 8*l.* 6*s.* 8*d.* duplicates, is	12	10	0	50	0	0	650	0	0

Thus the sum of 100*l.* lent in shilling loans redeemed at the end of a week, at compound interest would amount in one year to 45,690*l.* 7*s.* 0½*d.*

Mr. Barrington, the founder of the Mont de Piété at Limerick, stated in a petition to parliament, in 1837, that there were 700 pawnbrokers in Ireland, whose incomes, averaging 900*l.* each, amounted in the aggregate to 630,000*l.* per annum. (Petition 59, *App. to 2nd Report on Public Petitions, Session* 1837-8.) The pawnbrokers of Ireland, in a counter-petition, asserted that the number of their body did not exceed 440, and that, with the exception of some of those resident in Dublin, Cork, Limerick, and Belfast, their average incomes did not exceed 400*l.* per annum. (Petition 398, *App. to 24th Report on Petitions, Session* 1837-8.) Probably the truth may be found between these contradictory statements. Mr. Barrington was engaged at the time in founding the Limerick Mont de Piété, as a means of providing funds for the public charities of that city. He erected buildings at his own expense, and sent competent persons to Paris to make themselves acquainted with the mode of conducting the Mont de Piété in that capital. A capital of 4000*l.* was raised in debentures bearing interest at 6 per cent.; and the Limerick establishment was opened on the 13th of March, 1837, under the control of a committee, consisting of the two city members, the mayor and chief police magistrates, and the Protestant and Roman Catholic bishops. In the course of eight months 13,000*l.* had been lent on 70,000 pledges at a rate of interest amounting to one farthing per month for a shilling, no charge being made for duplicates. Six-sevenths of the amount advanced was in sums under 5*s*. Four months after the establishment was opened, the value of articles redeemed on Saturdays averaged about 140*l.*, the interest on which amounted to 3*l.* 3*s.* 6*d.*, while the pawnbroker's charge would have been 9*l.* Towards the close of the year 1839, Mr. Barrington published a short pamphlet showing the further progress of the institution. The capital had been increased to 15,350*l.*, and a clear profit of 1736*l.* had been realised since March, 1837. Small sums are lent to poor persons of known respectability of character on their personal security. This plan is attended with valuable effects upon the conduct and character of the poorer classes.

In Appendix E, 'Poor Inquiry (Ireland),' there is an account of the Ahascragh Loan Society, which shows that where individuals can be found to superintend the details, the ruinous plan of applying to pawnbrokers may be partially obviated. This Society had borrowed 720*l.*, partly from the county Galway trustees, which sum had been disposed among 400 borrowers, and no loss had occurred during the two years in which the Society had been in operation, chiefly in consequence of the attention of the Rev. H. Hunt, the treasurer. In the evidence taken at an examination by the Commissioners of Inquiry in the county Leitrim (p. 93) it was stated that there were no pawnbrokers in the barony; but a class of men called usurers are to be met with in every direction, 'and they bind both borrowers and sureties by solemn oaths to punctual repayment of the principal, and of the interest, which is exorbitant in proportion to the smallness of the sum lent.' The witness, who was a magistrate, further stated that a case had recently come before Lord Clements and himself, in which a man had bound himself to pay 12*s.* a year in quarterly instalments for the use of 15*s.* principal. Such facts show the expediency of affording every encouragement to establishments conducted under the immediate control of the law. In some instances in Ireland pawnbrokers keep spirit-shops under the same roof or in an adjoining house. The Report just quoted states that people were beginning to lose their reluctance to wear the forfeited property of their neighbours; and most of the poor persons examined stated that a few years ago they were ashamed to go to the pawnbrokers, but this feeling appeared then to have been much weakened. The scarcity of capital in Ireland occasions many individuals to have recourse to pawnbrokers for purposes unknown in England, such as obtaining the means of purchasing a pig or buying seed.

In some of the British colonies the regulations for pawnbrokers appear to be very imperfect, if not unjust. The following table, showing the sums for which goods were redeemed for a poor woman at Hobart Town, is from the 'Austral-Asiatic Review' of Nov. 12th, 1839:—

Articles.	Amount.		Interest per week.			
Gown ..	3*s.*	0*d.*	3	weeks' interest	0*s.*	9*d.*
Cloak ..	4	0	4	ditto	1	4
Kettle ..	2	6	10	ditto	2	1
Jacket ..	2	0	8	ditto	1	4
Gown ..	3	0	8	ditto	2	0
Principal	14	6	Interest	. .	7	6

The duplicates all contained the following notice:—'This duplicate must be renewed or the pledge redeemed within *six* months from the date hereof, or the article will be *forfeited*.'

The Mont de Piété is an institution of Italian origin. [MONT DE PIETE.] Leo X. (1513-21), or, as some authors say, Pope Paul III. (1534-1549)), sanctioned the establishment of the first of these institutions. It is said however that a Monte di Pieta was founded at Parma in 1458. [PARMA.] One was formed at Amsterdam, 1568; Augsburg, 1 . Brussels, 1691; Antwerp, 1620; Ghent, 1623; Pa 1777. In 1661 a project existed for establishing Mont de Piété in England, and the following is the title of a pamphlet which was printed in London in the above year in connection with this scheme, which however was never carried into effect:—'Observations manifesting the conveniency and commodity of Mount Pieteyes, or Publick Bancks for Relief of the Poor or Others in Distress upon Pawns.' It is extremely doubtful whether a public institution for lending money on pledges would answer in London. Many branch establishments would be necessary, and they would scarcely be so economically conducted as the establishments belonging to private individuals. To give such an institution a monopoly resembling that which the Post-office possesses, would never be thought of in this country. The rates of interest charged by pawnbrokers are high; but the average profits of their trade are not so inordinate as might be inferred from a hasty glance at the preceding tables, which nevertheless fully prove, that having recourse to pawnbrokers is an improvident mode of raising money. In 1838 a company was formed in London called the 'British Pledge Society,' which proposed lending money at one-half the rate of interest allowed by the 39 and 40 George III., c. 99, and without making any charge for duplicates. This society also pledged itself to make good losses in case of fire, for which usually pawnbrokers are not liable. The Bill of incorporation, after being read a first time in the House of Commons, was abandoned.

There is a Mont de Piété at Moscow on a very extensive scale, the profits of which support a foundling hospital. They are numerous in Belgium. From a paper read by Rawson W. Rawson before the London Statistical Society in 1837, the following appear to be the terms of the Mont de Piété of Paris:—'Loans are made upon the deposit of such goods as can be preserved to the amount of two-thirds of their estimated value; but on gold and silver, four-fifths of their value is advanced. The present rate of interest is 1 per cent. per month, or 12 per cent. per annum. The Paris establishment has generally from 600,000 to 650,000 articles in its possession, and the capital constantly outstanding may be estimated at about 300,000*l*. The expense of management amounts to between 50 c. and 65 c. on each article, and the profits are wholly derived from loans of 5 francs and upwards. Articles not redeemed within the year are sold, subject however, as in England, to a claim for restitution of the surplus, if made within three years.'

The statistical tables published by the French minister of commerce show the operations of the Mont de Piété of Paris and those of the large towns in France during the year 1833; and the following brief analysis of them may be useful, if it be desired to estimate the extent of similar transactions in the private pawnbroking establishments in the United Kingdom: in the absence of actual facts, it at least offers points for consideration. The number of articles pledged in Paris in 1833 was 1,064,068; average sum advanced on each, 14*s.* 11*d.* It is necessary to observe that, from the low rate of interest and the confidence inspired by an establishment under the immediate control of the government, the Mont de Piété is made use of by persons of a higher class than those who apply to pawnbrokers in this country. The number of articles redeemed was 849,861; on 172,915 articles the interest was paid and the duplicate renewed; 50,636 articles, on which the sum of 39,291*l.* had been advanced, were forfeited, being one-twentieth in number, but less than one-twentieth in value. At Metz, in the same year, the forfeited pledges were one in 13; at Strasbourg, one in 19; at Lyon, one in 20; at Marseille they formed the smallest proportion, being only one in 29. In eleven of the largest towns of France, including the above four, 731,086 articles were taken in pledge; but the sum advanced on each, being 9*s.* 2½*d.*, was not much more than half the value of those pledged in Paris. The average sum varied considerably, being as low as 4*s.* 10*d.* at Strasbourg, and as high as 17*s.* 1*d.* at Marseille. In Brest, Nîmes, Dijon, and Nantes, the average value of each of the unredeemed articles *exceeded* the average value of each of the total number of articles pledged.

PAX, an ecclesiastical instrument of ancient use in the Roman Catholic church. St. Paul, in several of his epistles, commands the professors of the Christian religion to 'salute each other with a holy kiss.' That this was literally practised in the first ages of the church, we learn from the apostolical constitutions, together with some particulars respecting the method of performing this ceremony. 'Let the bishop salute the church, and say, *The peace of God be with you all*: and let the people answer, *And with thy spirit*. Then let the deacon say to all, *Salute one another with a holy kiss*, and let the clergy kiss the bishop, and the laymen the laymen, and the women the women.' (Li. viii., c. 11, apud Cotelier, p. 345.)

The custom of giving the kiss of peace before the communion, in the more solemn service of the Roman Catholic church called the High Mass, is still kept up among the officiating clergy, as well as among the men and women of the different religious orders. So also it appears to have been practised by the laity during the whole of the middle ages, while the men and women were separated from each other. But when the sexes began to be mixed together in the less solemn service called the Low Mass, which began to take place in the twelfth or thirteenth century, a sense of decorum dictated to the bishops the use of an instrument called sometimes a *Pax*, sometimes *Tabula Pacis*, and sometimes *Osculatorium*, which the priest kissed first, then the clerk, and lastly the people who assisted at the service, one after another, instead of the former kiss.

Among the constitutions of Walter de Grey, archbishop of York, A.D. 1250, an *osculatorium* was one of the regular ecclesiastical ornaments, or rather implements, ordered to be provided in every parish church.

It was usually in the form of a metallic plate or tablet, with a support at the back, and had a representation of the crucifixion in front, either in relief or engraved. The magnificent pax of silver, engraved in niello, by Finiguerra, is still preserved at Florence.

The general disuse of this plate in modern times is attributed by Le Brun (*Explication Littérale, &c. de la Messe*, tom. i., p. 595) to certain jealousies which were found to arise among individuals, about priority in having it presented to them.

The use of the Pax was not among the ceremonies which were first abrogated at the Reformation in England: on the contrary, it was enforced by the ecclesiastical commissioners of Edward VI., and rendered more ostensible than it had been, as appears by the following injunction, published in the deanery of Doncaster, in 1548:—'The clerk shall bring down the paxe, and standing without the church-door, shall say loudly to the people these words: "This is the token of joyful peace, which is between God and man's conscience,"' &c.

(Du Cange, *Gloss.*, v. 'Osculatorium,' 'Osculum Pacis,' 'Pax;' Milner, 'On the Use of the Pax,' *Archæolog.*, vol. xx., p. 534; Burnet, *Hist. Reform.*, vol. ii., collect. P. ii., No. 21.)

PAXO, the smallest of the Ionian Islands, lies south-south-east of Corfu, being eight miles from Capo Bianco, the southernmost point of that island, and about ten miles west of the nearest point of the mainland of Epirus. Paxo is rocky, and is chiefly planted with olive-trees which produce the best oil in the Ionian Islands. The island is destitute of spring-water, and is deficient in corn and other necessaries, which are brought in from Corfu and other places. Its surface is reckoned at 26 square miles, and the population by the census of 1834 was 5284 inhabitants. The principal village in the island, called Porto Gai, has a good harbour, and is the residence of the authorities. Two other hamlets, Loca and Longos, lie also by the sea-coast. The small island called Anti-Paxo, three miles south-east of Paxo, is about three miles in circumference, and is inhabited by fishermen and a few shepherds. (Neigebaur, *Ionische Inseln.*) [IONIAN ISLANDS.]

PAZ, LA, a town in Bolivia, situated near 16° 30′ S. lat. and 68° W. long. It stands in a ravine probably more than 1000 feet below the table-land of the lake of Titicaca [BOLIVIA], on some hills which are scattered over the ravine, on the northern side of which rises the elevated peak of Illimani. The ravine and town are intersected by a river, the Chuquiapo, which breaks by a narrow gorge through the eastern chain of the Bolivian Andes, and is one of the remotest sources of the Rio Madeira. The ravine is enclosed by high and steep mountains, and contains little level ground; but it is cultivated with great care wherever cultivation is practicable. The streets of the town are very irregular, and some of them extremely steep. It contains many extensive dwelling-houses, built in the Spanish fashion; but the roofs are not flat, and they are covered with tiles on account of the snow, which, during the winter, falls in this ravine. The greater part of the houses however are only mud-huts, and inhabited by Indians. La Paz is the most commercial town in Bolivia. All the merchandise designed for the consumption of Chuquisaca, Potosi, and Cochabamba, is conveyed to this place from the coast of Peru, and hence carried into the interior. The surrounding country produces no article of export except gold and bark, which are collected in considerable quantity on the eastern declivity of the eastern range of the Bolivian Andes. The population exceeds 20,000.

(Temple's *Travels in various parts of Peru*; Pentland, in *London Geog. Journal*, vol. v.)

PEA. The garden pea (*Pisum sativum*) is a native of the south of Europe, but sufficiently hardy in a young state, or when its development is not much extended, to bear our winters when they are moderate, and when the plants have, as in gardens generally, a sheltered situation.

The pea, together with the bean and kidney bean, are enumerated as the legumes cultivated by the Romans; and these indeed comprise the principal species of leguminous plants in the kitchen-gardens of Britain at the present day. Among these the pea ranks first in importance and general usefulness. It had probably been introduced into this country at an early period, for peas are mentioned by Lydgate, a poet of the time of Henry VI., as being hawked in London. It appears however that for at least a century afterwards, in Queen Elizabeth's time, they were either not very common, or the manner of obtaining them early was unknown, for Fuller states that in the last-mentioned reign peas were brought from Holland, and were accounted 'fit dainties for ladies, they came so far and cost so dear.'

The varieties of the pea are numerous. The best account of them will be found in the 'Transactions of the Horticultural Society,' 2nd series, vol. i., where 43 varieties, comprising no fewer than 175 synonyms, are arranged and described.

The following is a selection of the more useful varieties:—

For early sowing—Early Dwarf.
Early Frame.
Early Charlton.
D'Auvergne, a particularly excellent sort.
For the principal summer crop—
Blue Prussian.
White Prussian.
Groom's Superb Dwarf Blue.
Dwarf Green Marrow.
Knight's Dwarf Marrow.
For late sowing—Knight's Tall Marrow.

There are some varieties of peas destitute, or nearly so, of the internal tough lining of the pods; these are called *sugar peas*, and their pods are eaten cooked in the manner of kidney beans. The best variety of this class is the Large Crooked Sugar, which will likewise be found a very good sort for use in the ordinary way.

The soil for peas ought to be fresh and well stirred, but not too rich; for in the latter case a luxuriant growth is induced without fertility.

The times of sowing are, in November for the earliest crop, and at intervals of a month, three weeks, or a fortnight, as the season advances, till Midsummer. The produce from any that may be sown after this period is very uncertain; as is indeed the case with the November and other sowings previous to those of spring. The shelter afforded the young plants in winter by spruce branches or temporary awnings is of course beneficial. Various plans have been suggested for forwarding peas under glass, so as to transplant in the end of February or in March into the open ground. The best mode is to sow in small pots, and at the proper season to turn out the plants with the ball of earth and roots as entire as possible, to plunge them at short intervals in rows, and to shelter them by sticks of a branching nature and fan form.

The distance which should be allotted for the intervals between the rows of peas may be three, four, five, or six feet, according to the growth of the sort and richness of the soil. The plants should not be allowed to grow too thick in the rows, otherwise they are drawn up slender, without a due proportion of foliage on the lower part of the stem, which, in that case, as well as the leaves depending on it, is apt to become unhealthy and to mildew.

Agricultural Cultivation.—The common pea is a vegetable too well known to require description. It is cultivated in the garden and in the field, and there are several varieties of it. The plant is naturally a creeper, having numerous tendrils, by which it lays hold of stronger plants and supports itself. The pods contain one row of round seeds, which at first are soft and juicy, in which state they are used for the table under the name of green peas. They afterwards harden and become farinaceous, and the stem dries up. In this state they are thrashed and stored for use like corn, and serve chiefly to fatten hogs. The straw is given to cattle and sheep in winter.

There are some varieties of peas the stems of which do not rise or creep, but remain short, and hence are called dwarf peas. These are preferred for early sowing in the garden, and likewise when they are cultivated in the fields to be gathered in a green state. Every gardener strives to raise early peas, and the first which are brought to the London market are sold for a very great price. As soon as they are more common, such quantities are sometimes raised in the fields, that the price scarcely defrays the expense of gathering and bringing to market. When the market is not overstocked, this crop is very profitable, as it does not exhaust the land, and there is good time for a crop of tares or turnips after the peas in the same season. But the usual purpose for which peas are cultivated in the regular course of husbandry, is to fatten hogs. A white sort, which readily splits when subjected to the action of millstones set wide apart so as not to grind them, is used in considerable quantities for soups, and especially for sea-stores. There is also a blue sort which answers the same purpose. The hog pea is of a grey or dun colour.

Peas contain much farinaceous and saccharine matter, and are therefore highly nutritious; no other seed surpasses them in this quality, except the seed of the French bean (Phaseolus). But this is refused by most animals in the raw state, owing to a certain toughness, which makes them adhere to the teeth; and, even when boiled, they are not relished by them.

As food for hard-working men, peas are excellent when well boiled and mixed with some animal fat, or the liquor in which bones have been long and slowly boiled to extract the gelatine. In some countries peas-meal is baked into hard cakes, with or without oatmeal or barley-meal. These cakes are nutritious, but are of difficult digestion, except where custom and hard labour have inured the stomach to their use.

The soil best suited to the growth of peas is a light or sandy loam of some depth, and in good heart: the usual preparation of it is by repeated deep ploughings and pulverising with harrows or other instruments. It is not adviseable to manure the land immediately for peas, as it makes them throw out abundant stems at the expense of the produce in pods. They follow well after barley in which no clover has been sown, and are a good substitute for clover where there would be a danger from the too frequent repetition of clover on the same land. When clover has failed, peas supply its place, the ground being ploughed up before winter, or early in spring, and well pulverised. The wheat is not always so good after peas as after clover, when the clover is a good crop; but it is well known that if the clover fails, the wheat will also suffer. It is therefore better to have peas, than to risk sowing wheat after a thin crop of clover. If the peas are not well hoed, and do not cover the surface, the land will be full of weeds; but with good management it may be looked upon as a cleansing crop. Many farmers consider peas as a very uncertain crop; but they are only so when the land is carelessly cultivated. They are, no doubt, often injured by want of moisture in the soil, or by an excess of it; but deep ploughing will prevent the former, and careful draining the latter. If peas are sown on land which is exhausted, or naturally very poor, no certain crop can be relied on. It sometimes happens however that an excellent crop is obtained against all probability, considering the state and tillage of the land, owing to some fortunate coincidences of favourable weather, and in this case it would appear as if great care in the preparation of the soil were unnecessary, but this is not often the case, and no prudent farmer will trust to the chances, which are much against success. In nine cases out of ten a slovenly cultivation or an improper succession of crops is the cause of great disappointment and loss, and it may be laid down as a general rule, that no good farmer will trust to accident, when by a little care and attention and a reasonable expenditure he may almost ensure success.

Peas must not be repeated on the same land in less than 10 or 12 years, nor are they to be recommended on very stiff clays, on which beans are to be preferred. Wherever beans suit the soil, they are a much better preparation for wheat than peas, admitting of much more frequent and perfect hoeing, besides the application of an abundant coat of dung, of which the wheat reaps the benefit as well as the beans.

Peas should be sown as early as the ground will admit of being worked; and in very mild winters January is a very good time for sowing peas, which are intended to be gathered green, in a sheltered situation sloping towards the south-west. The hog peas may be sown in February or March; and if they are horse-hoed, and the earth is raised against the young plants, they will not suffer from a moderate frost. When peas are drilled at 2 feet or more between the rows, it will not take above two bushels to drill an acre. The old method of sowing peas broadcast and ploughing them in is now seldom practised, and to sow them and harrow them in is nowhere recommended; the birds in this case having much too great a share of the seed. When peas follow clover, the practice of dibbling them into the sward, which has been turned over with the plough, is much to be preferred. Wherever dibbling is generally practised, and there are sufficient hands to put the seed into the ground at a reasonable time, it should be preferred for every kind of crop that can admit of the hoe in the intervals.

When peas are sown later than usual, it is useful to steep the seed a few hours, in order that it may vegetate sooner. A week may often be gained in the coming up of the crop by this means.

The Everlasting Pea, which is so well known in our gardens, has been recommended to be cultivated in the fields for green fodder for horses, which are said to eat it readily. In land which has been well manured, it will produce a very great weight of green food; and there are probably varieties of it more succulent and sweeter than others. If it could be established in a field, it would produce abundant food for several years in succession, without any other cultivation than hoeing out the weeds and stirring the soil around the plants. The seed should be sown in rows, and the plants thinned out by the hoe, so as to stand a foot or 15 inches apart; they would then have room to grow out, and would cover the ground completely. By transplanting year-old plants, a still greater crop might be obtained. It is at least worth a trial.

Peas should be drilled in rows at such a distance as to admit the horse-hoe between them. They should be horse-hoed repeatedly until the stems are so long as to fall down and cover the intervals: a slight earthing of the rows with a plough has the effect of keeping the stems from the ground and allowing the air to circulate under them, by which the podding is much encouraged; for in wet seasons the stems are apt to lie on the wet ground and to rot. When the seed is ripe in the pods on the lower part of the stalks, the crop should be reaped, or many of the pods will burst, and the seed be lost. The reaping is performed by pulling the stems from the root by hand, or by means of two reaping-hooks, which partly tear up the stems, and partly cut them off. They are then gathered into small loose heaps, and left to dry. After being turned over till they are quite dry, they are carted to the stack or barn. Unless the quantity be considerable, so as to make a large stack, it is advisable to put them in a barn, because they are generally thrashed out soon after harvest, when the hogs, having run for a time in the stubbles, are put up to fatten. When the peas are stacked, many of the pods are necessarily exposed to the depredation of birds; and, if they escape this, they burst, and the seed is lost.

The produce of an acre of good peas is from 30 to 40 bushels, and the price somewhat higher than that of beans. They are consequently a profitable crop, and will well repay a little attention in the cultivation. If the land is not in sufficient order and heart to make it advisable to sow wheat after the peas, barley or oats may be advantageously substituted. If the peas fail, it may be necessary to clean the land with a fallow crop before any other corn is sown, for a bad crop of peas invariably leaves the land foul.

The straw or halm of peas, when well harvested, makes excellent fodder for cattle, and especially for sheep, which are very fond of the dry pods when the seeds have been thrashed out.

In some places they sow peas and beans together broadcast, and plough them in; the beans serve as a support to the peas, and a greater return is expected; but unless it be for the purpose of cutting them up for green fodder, as soon as the pods are formed, this practice is not to be recommended. In Flanders, peas, beans, tares, and barley are sometimes sown thick together, and form an abundant green crop, which is cut as soon as the flower is past, and given to the cows and pigs, which thrive well on this succulent food. The surface of the ground is so completely shaded, that no weeds can spring up; and as there has been no seed formed, little is taken from the soil. The land is immediately ploughed up and sown with another crop, such as potatoes or turnips, which sometimes are off the ground in time to allow wheat to be sown the same year.

PEACE RIVER. [North-Western Territory.]

PEACE OF RYSWICK. [Ryswick, Peace of.]

PEACH. The peach-tree (*Amygdalus Persica*, or *Persica vulgaris*) is generally considered to be more especially a native of Persia. It was known to the Romans, and brought to Italy, where it became distinguished by the name of *Persica*; and this name it still retains under various modifications in the different countries of Europe; thus, *peach* is evidently derived from *pêche* or *pêcher*, the latter being formerly written *pescher* by the French. But the peach is not indigenous solely in Persia, for it has been found growing wild in various parts of Turkey in Asia. Pallas describes it as existing in the more southern parts of the Caucasus. From the frequency of its occurrence in a wild state and the perfection which it attains under the most limited share of cultivation in regions situated between 30° and 40° of latitude, these parallels may be presumed to include its favourite habitat. Isothermal lines describe however a wavy track; and the peach may even find a congenial climate in a considerable extent on both sides of the above limits; but the locality must be very peculiarly circumstanced in which it will acquire full perfection beyond the 48th parallel on the one hand; and, on the other, its deciduous nature, requiring a fixed season of rest, unfits it for the continued high temperature of a tropical climate.

It is to be regretted that there are as yet no perfect registers of the temperature of places where the peach in its natural state attains the greatest perfection. Such would at once form the surest guide for the establishment of principles for the regulation of that artificial climate which the tree requires to ensure its fruiting in perfection in Britain, and for which purpose the aids of glass and fire-heat are provided.

The peach withstands our winters unhurt, if they are not unusually severe. It even succeeds in America exceedingly well as a standard, in latitudes where the winters are much more intense, but the summers hotter, than with us. This is in conformity with the well ascertained fact, that all deciduous trees suffer less from severe frost in winter when their wood is perfectly matured by sufficiently warm summers, than when grown in climates where they cannot enjoy that degree of summer heat which they are naturally adapted for, and which they require for the due formation of their tissues. Hence, in the north of England, young peach-trees in the open ground will be partially injured by a degree of frost which, though of equal intensity, will not injuriously affect similar plants in the neighbourhood of London. The peach also succeeds as a standard in Italy, the south of France, and other continental countries of Europe having summers equally hot; but it may be observed that where the mean temperature of the summer months is above 70°, or that of the warmest month above 75°, as is the case at Rome, and still higher at New York, the *melting* varieties of the peach do not possess that rich succulence which they acquire against a south wall under the more moderate summer heats of the climates of London or Paris. On the contrary however, the *firm-fleshed* or *clingstone* peaches, which are little esteemed in this country, are preferred in America and other places subject to extreme summer heat.

If the mean temperature of February amount to 40°, and that of March to 44° or 45°, the peach-tree will be in full flower against a wall with a south aspect about the last week in March; and the general crop will be ripe in the last week of August or first week of September, provided the mean temperature of April be 49°, May 55°, June 61°, July 64°, and that of August 63°. This period of *five* months required for the maturation of the fruit from the time of flowering, on the open wall, may be reduced to *four* by means of fire-heat and the protection of glass; but it cannot be advantageously diminished any further. This fact being borne in mind, it is easy for the gardener to know at what time to commence forcing his peaches in order to obtain a crop in a given month.

From the natural climate and habit of the peach-tree, it is obvious that when forced it must be flowered under a comparatively low degree of temperature. It cannot therefore be well forced simultaneously with the vine, for the temperature of March, which in that climate serves to bring the peach into flower, does not unfold the buds of the vine, this being only effected a month or six weeks farther in the season by a mean temperature of 55°. The peach may be subjected at first to a temperature of 45°, but not exceeding 55° till the flowering is over, after which it may be gradually raised to 60°, and not exceeding 65°, till the substance of the stone is indurated, after which from 65° to 70° may be allowed. This is to be understood as referring to the application of fire-heat. Even in the total absence of the latter, sun-heat will frequently raise the temperature much higher; but in this case a large portion of air should be supplied, not however all at once after the temperature of the house is found too high, but gradually as the temperature increases. Air should be always freely admitted through the day when the weather is at all favourable.

Light is so essential, that unless peaches be trained near the glass, the fruit will neither acquire due colour nor flavour. Vicissitudes of dryness and moisture must be avoided. The roots should be well supplied with water before the fruit begins to ripen off, because at a later period none can be applied without deteriorating the flavour.

The management of the peach-tree can only be correctly understood by those who are aware of the disposition of its buds and its mode of bearing. The leaves on the shoots of the current season are produced either singly, in pairs, or in threes from the same node. In the course of the summer, or early part of autumn, a bud is formed in the axil of every individual leaf, and these are termed single, double, or triple *eyes*, or buds, according as one or more are produced at each node. In the following season, these buds develop themselves either as flower-buds or young shoots, and previously to pruning it is necessary to distinguish the one description from the other. The flower-buds are plump and roundish; the wood-buds are more oblong and pointed, and one of these is generally situated between flower-buds in the case of triple buds occurring at the same node. It is therefore expedient in pruning to shorten a shoot to these triple eyes if possible, or in their absence to a leaf-bud, but never to a fruit-bud only, for no shoot could be prolonged from it, nor would the fruit attain perfection, owing to the want of leaves in immediate connection with its footstalk. In selecting buds for the purpose of propagation, *single* wood-buds only should be chosen.

The mode of bearing is solely on shoots of the preceding summer's growth.

The peach is propagated exclusively by budding; rarely on the peach stock, but frequently on the almond, especially in France. In this country however it is propagated almost entirely on the plum stock, which is not only much hardier, but also possesses the property of spreading its roots nearer the surface than either of the two preceding kinds; thereby affording to the peach a more congenial nourishment in consequence of the roots being within the influence of the solar heat. Whereas the peach stock tends to strike downwards strong tap-like roots beyond the depth of the stratum warmed by the summer-heat; and although the latter trees grow vigorously for a few years, or so long as the roots have not penetrated too deep, yet they afterwards become sickly, their foliage becomes narrow, and acquires a yellowish colour, and the trees ultimately perish. The *muscle* and *white pear-plum* are the varieties of plum stocks on which the peach is budded; the latter is esteemed the best. The French prefer the St. Julien plum stock, which answers exceedingly well.

The peach succeeds in any rich fresh loamy soil; but the subsoil, like that for all fruit-trees, ought not to be retentive, and a very complete mode of drainage is absolutely necessary. It would also be desirable that the roots should not be allowed to penetrate deeper than two feet from the surface. No objections could be made against the roots following their natural tendency downwards to whatever distance they might go, if their extremities were at the same time in a medium congenial to the peach as regards temperature; but this cannot be the case in Britain, unless perhaps some chalk subsoils may form exceptions. It is known by experience, that when the roots are in a medium of much lower temperature than the mean of that of the atmosphere during the growing period, the trees do not thrive, nor does the fruit, under such circumstances, acquire flavour; mildew makes its appearance, and no application will effectually cure it without inflicting a material injury on the foliage. The best remedy for mildew is to take up the tree carefully in autumn, renew the soil, and replant the tree, spreading the roots near the surface. When peach trees are young, they generally grow very luxuriantly; and if dung be abundantly incorporated with the soil, disease is almost certain to manifest itself by the exudation of gum. It is therefore adviseable to defer the application of manure till the trees begin to bear fruit, and then to apply it only as a top-dressing, so as to maintain a vigorous but not an over-luxuriant state of growth, and to retain the new roots near the warm surface of the soil.

Various modes of training the peach have been adopted, h different degrees of success. That of course has proved best which admits of the most equal distribution of sap throughout the respective branches, and likewise the production of a sufficient number of well-placed shoots for replacing those that have once borne fruit, the shoots being only useful for such purpose in the season immediately following that in which they are produced. The fan method, and a modification of it called Seymour's training, are most in conformity with the above principles. A common error in the fan method is that of disposing a few of the first produced branches so as to represent equi-distant radii; the consequences of such disposition are an excessive degree of vigour in the central and most upright, but at the same time those inclining horizontally become comparatively weak, linger for a few years, and then die off. Their share of the sap is soon appropriated by the more vertical branches, some of which will assume the character of stems, and prove unsuitable for producing fruit-bearing shoots. Cutting these back is frequently the only alternative in order to obtain other shoots for the purpose of furnishing the lower part of the wall. By this misdirection of the energies of the tree, several years' growth is wasted, and when it becomes necessary to cut out such large branches, the tree receives a shock which renders it incapable of bearing such fine fruit as a more skilful management will ensure. It may be briefly affirmed that all methods of training are bad which admit upright shoots to compete with horizontal ones; for the former will grow with a vigour ten times greater, in many instances, than the latter, owing to the strong vertical tendency of the sap. Although the ascendency gained by a vertical shoot over a horizontal one is considerable in the current season of their production, yet it bears but a trifling ratio to that which would be gained in successive seasons, were the vertical portion allowed to proceed without interference from the pruning-knife. If however a central vertical shoot be annually trained, and uniformly cut at the winter pruning to within a few buds from its base, no material injury would then result to the side branches, the vertical tendency against them being thus limited to a single summer-shoot. This principle is the basis of the following mode of training.

In cutting back the central shoot, two buds, well situated for producing side branches, and a third for an upright, must be left. The first production of side branches, which are intended to produce the lower radii of the fan, must be trained at some elevation in the first instance, and afterwards brought to a horizontal position; and they should not be subdivided. Those however obtained in the following season may be allowed to form two each, if sufficiently vigorous, at some distance from their base, and as the divergence affords room. The branches produced after these last mentioned, and indeed all the upper ones, may be subdivided into two, or even three. By this method of training the lower branches become strong, and acquire a well established communication with the roots before the upper are in existence, so that there is little danger of their dying off, as usually happens when horizontal and vertical branches are started at the same time.

By repeating the process here detailed, all the principal branches are ultimately produced, to the number of between thirty and forty, and disposed in a fan-like form, diverging not exactly from a common centre, but from a short axis. These branches support the shoots on which, during the second season of their existence, the fruit is borne. Buds for the origin of these shoots should be selected at the distance of every twelve or fourteen inches along the upper side of the branches, that being the side from which they are obtained with the greatest facility, owing to the upward tendency of the sap. As these shoots are being prolonged during the summer, they should be trained so that the foliage may have the fullest exposure to light; but although the foliage of one shoot ought not to overshade that of others, yet the naked branches are benefited by the shade of leaves, for old bark exposed to the direct rays of the sun is apt to be scorched.

The shoots produced and trained during the summer as successional bearing ones, must be shortened considerably at the ensuing winter's pruning, and care must be taken not to cut above a node where there is only a blossom-bud or buds, but to one that is seen to have a wood bud, that such as a shoot will proceed from. In the following spring the blossom-buds are unfolded, and soon after the wood-buds begin to push the rudiments of shoots, one of which next the base of each fruit-bearing shoot, must be preserved and encouraged with special care, in order to supply the place of those that are bearing fruit. The fruit-bearing shoots being useless for such purpose a second time, must therefore be cut away at the following winter pruning, when the young shoot, retained during the summer, is shortened like its predecessor, and trained for the purpose of bearing fruit and producing a successor, which likewise becomes subject to the same routine treatment.

The preceding directions are to be followed in order to the essential pruning, the development and maintenance of the form of the tree; but as a great number of superfluous shoots will be produced, the mode of their removal requires to be noticed. The operation is termed disbudding, and it commences as soon as the young shoots can be laid hold of, but should be completed in a gradual manner. A portion of such front shoots as have no fruit at their bases are first removed, then part of those elsewhere situated, making exceptions of the lowest on each bearing shoot, for succession, and of the terminal one. By degrees all are removed excepting the two last mentioned and those from nodes where fruit is set and promises to attain perfection. Finally, the terminal ones and those left on account of having fruit at their bases are shortened, or stopped, to about three inches in length, or so as to leave several leaves for the purpose of maintaining the flow of sap and elaborating it for the nourishment of the fruit. Should these or the terminal shoots again push, such secondary shoots must be pinched off above the second leaf from the origin.

Thinning the fruit is generally done much too sparingly. The vigour of the tree should of course be taken into consideration. As a general rule, one fruit on each bearing shoot, or two at most, are all that ought to be left. By leaving too many the size of the fruit is diminished, so that the aggregate weight of flesh is probably but little if at all increased, whilst that of stones, in the great weakening of the tree, becomes materially so. Some remove the flower-buds to a considerable extent, a practice which is very proper. It is advisable however to preserve several on each shoot, in order that a choice may be made of one or two of those likely to take the lead.

The surface of the border should be frequently stirred; and when the weather is dry, watering will be necessary both for the border and foliage; but the use of cold spring water must be avoided. The ravages of the green fly (*Aphis Persicae*) must be carefully guarded against. The best known remedy is to dust the tree, after syringing, with snuff, or powdered tobacco leaves. Coping-boards, made to project about a foot, are of great utility in protecting the blossoms; but after the danger of frost is over, the coping ought to be removed.

The best varieties of peaches in cultivation at the present day in this country appear to have been obtained from France. Although designated by various English names, most of the sorts have been traced to be synonymous with the French peaches.

The different varieties admit of the following classification:—

I. *Leaves serrated, glandless.*

a. Flowers large	Clingstones	§ 1.
	Melters	§ 2.
b. Flowers small	Clingstones	§ 3.
	Melters	§ 4.

II. *Leaves crenated or serrulated, with globose glands.*

a. Flowers large	Clingstones	§ 5.
	Melters	§ 6.
b. Flowers small	Clingstones	§ 7.
	Melters	§ 8.

III. *Leaves crenated or serrulated, with reniform glands.*

a. Flowers large	Clingstones	§ 9.
	Melters	§ 10.
b. Flowers small	Clingstones	§ 11.
	Melters	§ 12.

Six more sections might be formed by admitting subdivisions of middle-sized flowers; but no varieties worthy of cultivation, and indeed very few of any description, being referable to such sections, they have been consequently omitted.

The following list contains the best varieties of peaches, arranged according to the sections to which they respectively belong in the above classification.

Section 2. Early Anne, Noblesse, Malta.

Section 4. Royal George, Royal Charlotte.

Section 6. Acton Scot, Grosse Mignonne, Barrington.

Section 8. Bellegarde, George the Fourth, Late Admirable.

Section 10. Pourpré Hâtive.

Section 12. Chancellor.

PEACOCK. [Pavoninae.]

PEAK OF DERBYSHIRE. [Derbyshire.]

PEAR, the wild pear-tree (*Pyrus communis*), from which the numerous cultivated varieties have originated, has a wide indigenous range extending over a great part of Europe and Asia, within the limits of temperate regions. It is to be met with in certain localities in the southern parts of Britain. The old varieties of pear are however getting rapidly out of cultivation, and giving place to others of recent origin, superior in quality, and much better adapted for this climate than the old kinds appear ever to have been. Few of the latter could be successfully cultivated without the aid of walls; whereas most of the new varieties produce abundance of excellent fruit on standards or dwarfs in the open ground. Even in France the old varieties are now decaying, although the climate is there most congenial to them.

The pear is chiefly propagated by grafting or budding on the wild pear stock, or on stocks raised from the seeds of cultivated pears, called free stocks; the former are however to be preferred. It is also grafted on the quince, which is most proper for dwarf trees, or for moist soil, and has also the effect of bringing the trees earlier into a bearing state. It may be also grown upon the medlar, and the white thorn (*Crataegus Oxyacantha*), but on these the disparity of growth between the respective stems occasions a short duration of the union. The enlargement of the pear-stem in the case of strong growing varieties is indeed generally too much for quince stocks. There are several varieties of the quince, and the sort that has the broadest leaves and which has the nearest correspondence in regard to horizontal growth with that of the pear should be preferred for stocks.

The pear-tree will thrive in any rich loamy soil; but it is only where the subsoil is naturally congenial, or rendered so artificially, that it will continue to produce good crops of well flavoured fruit. A clay subsoil is bad, and so is in fact any other that will hold water. Good drainage is absolutely necessary, and shallow planting cannot be too much recommended. The monks in former times were aware of the advantages arising from having the roots near the surface; for stones and slates have been found below old fruit-trees, which had been planted at monasteries once in their possession.

Manure is not so liable to prove injurious to the pear and apple as it is to stone-fruits. On the contrary, unless the trees be growing too strong, manure, judiciously applied, will always prove beneficial.

Pears are deemed worthy of the expense of walls, but this is often an unnecessary expenditure for want of a properly formed border, and thorough draining, where the subsoil renders such necessary. Brick rubbish is a good bottoming; or a bed of concrete, two or three inches thick, laid sloping from the wall towards a drain in front, is unquestionably one of the best modes that could be practised; and it is the only effectual one to prevent the roots from penetrating beyond a limited depth; for they will often find their way through a stratum of stones or brick rubbish. The depth of soil need not exceed 2½ feet. The best season for transplanting is in the beginning of winter, or as soon as the leaves have fallen in autumn.

Standard trees may be planted from 20 to 30 feet apart, or where vegetables are intended to be cultivated, the distances may be 40 feet between the rows and 20 feet in the rows. Dwarf trees, or quince stocks, will not require more than 15 feet distance. Wall-trees should be at least 20 feet apart, and for some varieties 30 feet will not be too much.

The modes of training the pear-tree are various. Against walls, the three principal methods are the fan shape, its reverse the pendulous, and intermediately the horizontal, which is that most generally adopted. In the fan method the central part of the tree, from the upright position of the branches, or their near approach to such, is apt to become too strong. On the contrary, the pendulous training induces debility when the trees begin to bear heavy crops. By annually cutting back a central shoot to about a foot, and training branches horizontally, right and left, the vigour of the tree is equally distributed. It often happens that in this mode the branches only produce fruit towards their extremities. When this is the case, a shoot should be encouraged near the origin of the horizontal branch, and trained in the interval, and at some distance, say three feet; farther along the branches another may be laid in a similar manner, and so on, care being taken that each is stopped when its elongation reaches the place where another has its origin. These shoots will generally become as fruitful, after two or three years, as the portion of wood of the same age near the extremities of the branches themselves.

Training against espaliers was formerly more practised than at present. The difficulty of getting the old varieties to bear, apart from a wall, together with the expense of erecting the espalier, and the liability of its materials to decay, have no doubt tended to bring this mode into disuse. It is however worthy of remark, that a greater extent of foliage can be exposed to direct light by espalier training than by any other on an equal extent of ground. New varieties will do away with the objection of unproductiveness; and although the contact of metallic substances is not congenial to vegetable growth, yet the principal supports of the espalier might be constructed of cast-iron, which would prove an ultimate saving; the small intermediate wood work that would be requisite could be easily replaced.

In the cultivation of pears as standards, the head is allowed to take nearly its natural course, being only subjected to such regulations, by pruning, as are necessary to preserve the equality of the principal branches with regard both to strength and distance; and likewise to render the whole sufficiently thin, in order that the sun's rays may be freely admitted.

In some situations, many kinds of pears remain long unfruitful; the best means of rendering them otherwise is of course a most important desideratum. So long as circumstances are very favourable for the growth of wood, blossom-buds are not likely to be produced; the production of the latter results from a more inspissated state of the juices; and will not take place whilst a copious flow of sap is continued. This may be interrupted by ligatures, ringing, grafting, or other analogous means. But these means frequently afford only a temporary remedy, and a repetition of the process is at the expense of the energies of the tree, so that it is rendered too weak for future bearing. There is still a more important object which the above means are not calculated to affect. If the roots are in a cold subsoil or out of the reach of solar influence, the fruit will only acquire an inferior degree of flavour. If however the tree be carefully removed (for doing which autumn is the best season), the soil well dug, or even renewed, and the tree deprived of such roots as cannot be brought to a horizontal position, namely, that in which all the others should be placed when replanted, and if this be done as shallow as possible, a satisfactory check will be occasioned, fruitfulness induced, and flavour communicated.

The management of dwarf standards is similar to that required for tall standards, excepting that the head is formed at the height of one or two feet from the ground, instead of six, the usual height allowed for the stems of standard trees in orchards, or where under-cropping is carried on, as in market-gardens, where the dwarf-headed trees would obstruct the growth of vegetables for a considerable distance from their stem. Dwarfs however have some important advantages; a large head is sooner formed, and the fruit is not so liable to be blown down.

The French modes of training *en Quenouille* or *en Pyramide* cannot be strictly adopted in this country with advantage, owing to the richness of the soil and moisture of the climate, circumstances which are favourable to the production of shoots rather than fruit-buds, and this tendency is farther encouraged by shortening the shoots to the extent which the French recommend. In both these modes tiers of branches proceed from a central stem; in the pyramidal form the branches are horizontal, each tier being successively shorter than the one below. In the Quenouille the branches are curved downwards, and this mode might be successfully practised in this country, by leaving the shoots at full length, care being taken that all upright shoots are shortened in summer.

The pruning of standard pear-trees is usually confined to a winter regulation of the branches by thinning, and shortening where the subdivision of branches is desireable or where they are too weak. Wall and espalier trees require both a summer and winter pruning. In summer a number of shoots will be produced beyond that which will be required for training. If these are allowed to grow without interruption during a considerable part of the season, and then at once cleared away, the tree is apt to receive a shock from which it does not soon recover. If the shoots are shortened too much or too early, the buds, which would otherwise have proved blossom buds in the following spring, will immediately become excited (other channels for the flow of sap being cut off), and burst into shoots. [MORPHOLOGY.]

In order to avoid this, which is a case of frequent occurrence, a portion of these superfluous shoots should be first stopped at an early period, and afterwards another portion; by the middle of June part of them may be cut back to within two or three inches of their base; and thus by degrees the whole will be ultimately reduced, without any great or sudden derangement of the general flow of the sap. The winter pruning is attended with less vital danger to the tree. It consists chiefly in shortening spurs to the lowest fruit-buds and judiciously thinning them.

If borders are well made, there will be less occasion for raising the trees after they have been once planted. Still, after four or five years, it will, under all circumstances, prove advantageous to remove the trees from the wall, trench the border, and replant, spreading the roots near the surface in a horizontal direction, or inclining slightly downwards. Cutting the roots, without entirely removing the tree, is attended with the disadvantages arising from the partial loosening of the soil, and the difficulty of reaching the perpendicular portions of the root.

A selection of the best varieties of pears will be found enumerated in the article FRUIT.

PEARCE, ZACHARY, born 1690, died 1774, an eminent divine and scholar, and a prelate of the English church, who went through what has been the course of a large proportion of the persons of the class to which he belongs, the grammar-school, the university, a city living, a deanery, and a bishopric. He was the son of a distiller in Holborn, and a pupil in Westminster School, from whence he passed to Trinity College, Cambridge. At Cambridge he was best known as a polite classical scholar, and it was in 1716, before he took orders, that he published his edition of Cicero *De Oratore*. He inscribed it, at a friend's suggestion, to Lord Chief-Justice Parker, though he was not known to him, and this circumstance led to a friendship and patronage which were of the greatest use to him. The Lord Chief-Justice, being made Lord Chancellor soon after, took Mr. Pearce into his family as his domestic chaplain. Preferment now flowed in upon him. He was presented to the living of Stapleford Abbots in Essex, St. Bartholomew, near the Royal Exchange, and finally of St. Martin's in the Fields, London. This last appointment was in 1723. He was made dean of Winchester in 1739, in 1748 bishop of Bangor, and in 1756 bishop of Rochester, with the deanery of Westminster annexed, which he afterwards resigned. He wished also to resign his bishopric, that he might complete certain literary labours in which he was engaged, and have, as he expressed it, some interval of repose between the business of life and eternity. His application to the crown for permission to resign is a remarkable circumstance in his history. It was a new case, and there were difficulties about the appointment of a successor. Finally, the king, George III., intimated personally to the bishop that it must not be thought of. He died at Little Ealing, January 29, 1774.

Passing over single sermons, or small tracts, of which bishop Pearce was the author, he published, after his edition of Cicero's 'Orator,' an edition of Longinus, with a new Latin version; a Review of the Text of 'Paradise Lost;' and the 'Miracles of Jesus Vindicated;' but the theological work by which he is best known, and which is universally considered to be a most valuable addition to biblical literature, was not published till after his death, when it appeared with the title of 'A Commentary, with Notes, on the Four Evangelists and the Acts of the Apostles, together with a new translation of St. Paul's First Epistle to the Corinthians,' 2 vols. 4to., 1777. There are also four volumes of Sermons on various subjects by him, another posthumous work, published in 1778. An account of his life is prefixed to the Commentary

It remains to be added that he numbered among his friends some of the most eminent men of the age, and that he was highly esteemed and venerated throughout his long life.

PEARL. [Shells.]

PEARL FISHERY. The fisheries which are carried on to supply the market of the world with pearls are numerous, and some of them are of very antient date: thus the fishery at Catifa in Arabia, which produced the pearl bought by Tavernier for 110,000*l*., was celebrated in Pliny's time.

In the Old World, the west coast of Ceylon, that of Coromandel and the Persian Gulf, are among the more prominent stations. The Algerine coast and the Soolan Islands also furnish a certain share.

In the New World, the neighbourhood of St. Margarita, or Pearl Island, and other localities on the coast of Colombia, furnish a great many, and the Bay of Panama also contributes considerably; but the pearls which we have seen from the Western world, though many of them are large, cannot be compared with those of the East in shape, colour, and general beauty.

Of the latter fisheries, those at Ceylon and Tuticoreen (coast of Coromandel) are monopolies; the first belonging to the government, and the second to the East India Company; but they cannot be considered of much value, for the rent at which the fishery is let seldom covers the expenses of management, guarding, &c.

The Bahrein Islands (Persian Gulf) give a most abundant harvest of these beautiful molluscous secretions; perhaps the most abundant in the world. Sixty thousand tomauns of Bassorah, about 80,000*l*. sterling of our money, and often more, are derived from the fishery in about two months, the time during which it lasts, the commencement being in June. Here there is no monopoly; but any one may engage in the adventure upon payment of a tax on the produce to the government. The Persians principally are engaged in it, and the divers are of that nation.

The Western pearl fisheries, especially those on the coast of Colombia, must have been very valuable once. Seville alone is said to have imported upwards of 697 lbs. in the year 1587. The second Philip's celebrated pearl, which weighed 250 carats, and was valued at 150,000 dollars, came from Margarita. These prizes were not forgotten in 1825, when joint-stock companies raged. One company undertook the prosecution of the Colombia fishery, and another embarked in that of Panama and the Pacific, both with about the same success; for in 1826 they were abandoned. Some fine specimens of the shells of Mollusca were sent home by one of them. The Algerine ground was also, we believe, undertaken by an English company in 1826.

The pearls which are the objects of these fisheries are found in the shells of *Meleagrinae*, or pearl-oysters, as they are called, and principally in those of the species named *Avicula* or *Meleagrina margaritifera*. The best ground is considered to range at depths varying from 6 to 8 fathoms; and the divers, who usually are unhealthy and short-lived, are said to be able to remain generally from a minute to a minute and a half under water. Two minutes, four, and even six, have been mentioned; but constructed as the human respiratory and circulating system is, we should think the last-mentioned periods must be very rare. A submersion of a minute and a half is calculated to do mischief enough in ordinary cases. The following account of one of these fisheries is from Percival's 'Ceylon:'—

'There is perhaps no spectacle,' says the author, 'which the island of Ceylon affords more striking to a European than the bay of Condatchy during the season of the pearl-fishery. This desert and barren spot is at that time converted into a scene which exceeds, in novelty and variety, almost anything I ever witnessed; several thousands of people of different colours, countries, casts, and occupations continually passing and repassing in a busy crowd; the vast numbers of small tents and huts erected on the shore, with the bazar or market-place before each; the multitude of boats returning in the afternoon from the pearl banks, some of them laden with riches; the anxious expecting countenances of the boat-owners, while the boats are approaching the shore, and the eagerness and avidity with which they run to them when arrived, in hopes of a rich cargo; the vast numbers of jewellers, brokers, merchants, of all colours and all descriptions, both natives and foreigners, who are occupied in some way or other with the pearls, some separating and assorting them, others weighing and ascertaining their number and value, while others are hawking them about, or drilling and boring them for future use;—all these circumstances tend to impress the mind with the value and importance of that object which can of itself create this scene.

'The bay of Condatchy is the most central rendezvous for the boats employed in the fishery. The banks, where it is carried on, extend several miles along the coast from Manaar southward off Arippo, Condatchy, and Pomparipo. The principal bank is opposite to Condatchy, and lies out at sea about twenty miles.' After the survey of the state of the beds and the consequent report to government, the particular banks to be fished are put up for sale to the highest bidder, and are usually purchased by a black merchant. The government however sometimes judges it more advantageous to fish the banks on its own account, and to dispose of the pearls to the merchants.

The banks are divided into three or four different portions, which are fished annually in succession. These portions are completely distinct, and are set up separately to sale, each in the year in which it is to be fished. A sufficient interval is thus given to the oysters to attain their proper growth; and as the portion first used has generally recovered its maturity by the time the last portion has been fished, the fishery becomes almost regularly annual, and may thus be considered as yielding a yearly revenue. The oysters are supposed to attain their complete state of maturity in seven years.

The fishing season commences in February and ends about the beginning of April. The period allowed to the merchant to fish the banks is six weeks or two months at the utmost; but there are several interruptions which prevent the fishing days from exceeding more than about thirty. If it happen to be a very bad season, and many stormy days intervene during the period allotted, the purchaser of the fishery is often allowed a few days more. 'One considerable interruption proceeds from the number and diversity of holidays observed by the divers of different sects and nations who are employed.' Many of the divers are of a black race, known by the name of Marawas and Parawas, who inhabit the opposite coast of Tuticoreen; these people, although of the Malabar caste, are Roman Catholics, and leave off work on Sundays to attend prayers at the chapel of Arippo.

The boats and donies employed in the fishery do not belong to Ceylon, but are brought from the Coromandel and Malabar coasts. The divers from Colang are accounted the best, and are only rivalled by the Lubbahs, a tribe of Moors, who remain on the island of Manaar for the purpose of being trained in this art. Previous to the commencement of the fishery, all the boats rendezvous at Condatchy, and it is here that they are numbered and contracted for. They regularly sail out and return together.

'A signal gun is fired at Arippo about ten o'clock at night, when the whole fleet sets sail with the land-breeze. They reach the banks before day-break, and at sun-rise commence fishing. In this they continue busily occupied till the sea-breeze, which arises about noon, warns them to return to the bay. As soon as they appear within sight, another gun is fired and the colours hoisted, to inform the anxious owners of their return. When the boats come to land, their cargoes are immediately taken out, as it is necessary to have them completely unloaded before night. Whatever may have been the success of their boats, the owners seldom wear the looks of disappointment; for although they may have been unsuccessful one day, they look with the most complete assurance of better fortune to the next; as the Brahmins and conjurers, whom they implicitly trust in defiance of all experience, understand too well the liberality of a man in hopes of good fortune not to promise them all they can desire.'

'Each of the boats carries twenty men, with a tindal, or chief boatman, who acts as pilot. Ten of the men row and assist the divers in re-ascending. The other ten are divers; they go down into the sea by five at a time; when the first five come up, the other five go down; and by this method of alternately diving, they give each other time to recruit themselves for a fresh plunge.'

'In order to accelerate the descent of the divers, large stones are employed; five of these are brought in each boat for the purpose; they are of a reddish granite common in this country, and of a pyramidal shape, round at top and bottom, with a hole perforated through the smaller end sufficient to admit a rope. Some of the divers use a stone shaped like a half-moon, which they fasten round the belly when they mean to descend, and thus keep their feet free.

'These people are accustomed to dive from their very infancy, and fearlessly descend to the bottom in from four to ten fathoms water in search of the oysters. The diver, when he is about to plunge, seizes the rope to which one of the stones we have described is attached, with the toes of his right foot, while he takes hold of a bag of net-work with those of his left, it being customary among all the Indians to use their toes in working or holding as well as their fingers; and such is the power of habit, that they can pick up even the smallest thing from the ground with their toes almost as nimbly as a European could with his fingers. The diver thus prepared seizes another rope with his right hand, and holding his nostrils shut with the left, plunges into the water, and by the assistance of the stone speedily reaches the bottom. He then hangs the net round his neck, and with much dexterity and all possible despatch collects as many oysters as he can while he is able to remain under water, which is usually about two minutes. He then resumes his former position, makes a signal to those above by pulling the rope in his right hand, and is immediately by this means drawn up and brought into the boat, leaving the stone to be pulled up afterwards by the rope attached to it.'

The serious effects which so protracted a submersion must produce upon the human frame are manifested by a discharge of water from their mouths, ears, and nostrils, and, frequently, of blood. But this does not hinder them from going down again in their turn. 'They will often,' continues our author, 'make from forty to fifty plunges in one day, and at each plunge bring up about a hundred oysters. Some rub their bodies over with oil, and stuff their ears and noses to prevent the water from entering, while others use no precautions whatever. Although the usual time of remaining under water does not much exceed two minutes, yet there are instances known of divers who could remain four and even five minutes, which was the case with a Caffre boy the last year I visited the fishery. The longest instance ever known was that of a diver who came from Anjango in 1797, and who absolutely remained under water full six minutes.'

The last-named period seems almost incredible, but there is no reason to doubt Captain Percival's evidence. The chief horror and danger awaiting the diver are concentrated in the ground-shark. This animal is a common and fearful inhabitant of all the seas in these latitudes; and its terrors are so continually before the eyes of the divers, that they seek a vague safety in supernatural means. Before they begin diving, the priests or conjurers, who are known in the Malabar language by the name of *Pillal Karras*, or binders of sharks, are always consulted, and whatever the conjurer says to them is received with the most implicit confidence. The preparation which he enjoins them consists of certain ceremonies according to the caste and sect to which they belong, and on the exact performance of these they lay the greatest stress; nor will they on any account descend till the conjurer has performed his ceremonies. His advices are religiously observed, and generally have a tendency to preserve the health of the devotee. The diver is usually enjoined to abstain from eating before he goes to plunge, and to bathe himself in fresh water immediately after his return from the labours of the day. During the time of the fishery the conjurers stand on the shore till the boats return in the afternoon, muttering prayers, distorting their bodies into various strange attitudes, and performing ceremonies. All this time they ought to abstain from food or drink; but they sometimes regale themselves with toddy, till they are no longer able to stand at their devotions.

Some of the conjurers frequently go in the boats with the divers, who are greatly delighted at the idea of having their protectors along with them, and become additionally venturous. The zeal of the conjurers who go in the boats appears to be stimulated by the hope of a valuable pearl. As a body, these keepers of the consciences of the sharks reap a rich harvest; for, besides being paid by the government, they get money and presents of all sorts from the black merchants and those successful in fishing up the oysters.

'The address of these fellows,' adds Captain Percival, 'in redeeming their credit when any untoward accident happens to falsify their predictions, deserves to be noticed. Since the island came into our possession, a diver at the fishery one year lost his leg, upon which the head conjurer was called to account for the disaster. His answer gives the most striking picture of the knowledge and capacity of the people he had to deal with. He gravely told them that an old witch who owed him a grudge had just come from Colang, on the Malabar coast, and effected a counter conjuration which for a time rendered his spells fruitless; that this had come to his knowledge too late to prevent the accident which had happened, but that he would now show his own superiority over his antagonist by enchanting the sharks and binding up their mouths, so that no more accidents should happen during the season. Fortunately for the conjurer, the event answered his prediction, and no further damage was sustained from the sharks during the fishery of that year. Whether this was owing to the prayers and charms of the conjurer, I leave my European readers to decide; but certainly it was firmly believed to be the case by the Indian divers, and he was afterwards held by them in the highest esteem and veneration.'

The divers are paid differently, according to their private agreement with the boat-owners, either in money or with a proportion of the oysters caught, which they take the chance of opening on their own account: the latter is the method most commonly adopted. The agreements with the people who hire out the boats are conducted much in the same manner. They contract either to receive a certain sum for the use of their boats, or pay the chief farmer of the banks a certain sum for permission to fish on their own account. Some of those who pursue the latter plan are very successful and become rich, while others are great losers by the speculation. The spirit of gambling is more openly exhibited, for oyster lotteries are carried on to a great extent, and they consist of purchasing a quantity of the oysters unopened, and running the chance of either finding or not finding pearls in them. These lotteries are great favourites with European officers and gentlemen. The boat-owners and merchants lose some of the best pearls while the boats are on their return to the bay from the banks, as the oysters, when alive and left for some time undisturbed, frequently open their shells of their own accord: a pearl may then be easily discovered, and the oyster prevented, by means of a bit of grass or soft wood, from again closing its shell till an opportunity offers of picking out the pearl. 'Those fellows who are employed to search among the fish also commit many depredations, and even swallow the pearls to conceal them: when this is suspected, the plan followed by the merchants is to lock the fellows up and give them strong emetics and purgatives, which have frequently the effect of discovering the stolen goods.'

Captain Percival thus concludes his interesting account:—'As soon as the oysters are taken out of the boats, they are carried by the different people to whom they belong and placed in holes or pits dug in the ground to the depth of about two feet, or in small square places cleared and fenced round for the purpose, each person having his own separate division. Mats are spread below them to prevent the oysters from touching the earth, and here they are left to die and rot. As soon as they have passed through a state of putrefaction and have become dry, they are easily opened without any danger of injuring the pearls, which might not be the case if they were opened fresh, as, at that time, to do so requires great force. On the shell being opened, the oyster is minutely examined for the pearls; it is usual even to boil the oyster, as the pearl, though commonly found in the shell, is not unfrequently contained in the body of the fish itself.

'The stench occasioned by the oysters being left to putrefy is intolerable, and remains for a long while after the fishery is over. It corrupts the atmosphere for several miles round Condatchy, and renders the neighbourhood of that country extremely unpleasant till the monsoons and violent south-west winds set in and purify the air. The nauseous smell however is not able to overcome the hope of gain: for months after the fishing season, numbers of people may be seen earnestly searching and poring over the sands, places where the oysters had been laid to putrefy; and some are now and then fortunate enough to find a pearl amply compensates their trouble in searching after it. In 1797, while Mr. Andrews was collector, a Cooly, or com-poor fellow of the lowest class, got by accident the most valuable pearl seen that season, and sold it to Mr. Andrews for a large sum.

'The pearls found at this fishery are of a whiter colour than those got in the Gulf of Ormus, on the Arabian coast, but in other respects are not accounted so pure, or of such an excellent quality; for though the white pearls are more esteemed in Europe, the natives prefer those of a yellowish or golden cast. Off Tutucoreen, which is on the Coromandel coast, nearly opposite to Condatchy, there is another fishery; but the pearls found there are much inferior to those two species I have mentioned, being tainted with a blue or greyish tinge.

'In preparing the pearls, particularly in drilling and stringing them, the black people are wonderfully expert. I was very much struck with the instrument they employ in drilling, as well as the dexterity with which they use it. A machine made of wood, and of a shape resembling an obtuse inverted cone, about six inches in length and four in breadth, is supported upon three feet, each twelve inches long. In the upper flat surface of this machine holes or pits are formed to receive the larger pearls, the smaller ones being beat in with a little wooden hammer. The drilling instruments are spindles of various sizes, according to that of the pearls; they are turned round in a wooden head by means of a bow handle, to which they are attached. The pearls being placed in the pits which we have already mentioned, and the point of the spindle adjusted to them, the workman presses on the wooden head of the machine with his left hand, while his right is employed in turning round the bow handle. During the process of drilling, he occasionally moistens the pearl by dipping the little finger of his right hand in a cocoa-nut filled with water, which is placed by him for that purpose; this he does with a dexterity and quickness which scarcely impede the operation, and can only be acquired by much practice.

They have also a variety of other instruments both for sorting and drilling the pearls. To clean, round, and polish them to that state in which we see them, a powder, made of the pearls themselves, is employed. These different operations in preparing the pearls occupy a great number of the black men in various parts of the island. In the black town or pettah of Columbo, in particular, many of them may every day be seen at this work, which is well worth the attention of any European who is not already acquainted with it.' [AVICULA; MALLEACEA; SHELL.]

PEARL-ASH. [POTASSIUM.]

PEARL-HEN. [PAVONIDÆ.]

PEARL-OYSTER. [AVICULA; MALLEACEA.]

PEARL-RIVER. [MISSISSIPPI, STATE OF.]

PEARL-SPAR, a mineral which occurs massive, and also crystallized. The primary form is an obtuse rhomboid, the angle of which is but little different from that of the magnesian carbonate of lime; but the curvature of the planes prevents exact measurement. Cleavage easily effected parallel to the faces of the primary form. Hardness sufficient to scratch carbonate of lime readily. Colour whitish, greyish or yellowish, or brownish. Lustre pearly in general. Translucent. Opaque. Specific gravity 2·83.

Dissolves slowly in nitric acid. The fragments heated by the blow-pipe are attracted by the magnet.

It occurs abundantly in the lead-mines of the north of England, in those of Derbyshire, and also in Devonshire and Cornwall. It occurs also in many parts of Europe and America. Analysed by Hisinger it yielded:—

Carbonic acid	44·80
Lime	27·97
Magnesia	21·14
Oxide of iron	2·40
Oxide of manganese	1·59
	98·01

PEARL-STONE occurs massive in great beds in clay, porphyry, and secondary trap rocks. The structure is granular; it consists of roundish masses which vary in size, and which are sometimes from one to two inches in diameter; these are formed of thin concentric laminæ. The surface is smooth and shining, and the lustre pearly. Opaque. Translucent on the edges. Very easily frangible. Fracture uneven. Colour usually grey, but sometimes blackish or reddish brown. Hardness 5·5 to 6. Specific gravity 2·34.

Found at Tokay in Hungary, and in Spain.

A specimen from Spain gave, by Dr. Thomson's analysis—

Silica	76·100
Alumina	11·800
Peroxide of iron	2·284
Lime	3·090
Potash	3·500
Water	4·280
	98·604

PEARLS AND MOTHER-OF-PEARL consist, according to Mr. Hatchett, of carbonate of lime and albumen.

PEARSON, JOHN, born 1612, died 1686, a prelate of the church of England, and the author of 'An Exposition of the Creed,' a work which, having been greatly used up to the present time as a kind of text-book in the examination of candidates in divinity, has maintained a high celebrity, and been several times reprinted. He was a native of the village of Snoring, educated at Eton, from whence he went to Cambridge, and took holy orders in 1639, on the eve of the civil wars. Lord-Keeper Finch appointed him his chaplain, and presented him to the living of Torrington in Suffolk. But the chief scene of his labours as a parochial minister was in London, where he had the living of Saint Clement Eastcheap, and it was to the inhabitants of that obscure parish that the lectures were delivered which afterwards formed his celebrated Exposition, and to them that work when so published was dedicated. The first edition was in 1659, and in the same year he published the works of Hales of Eton, giving to them the title of 'Golden Remains of the ever memorable John Hales.' Hales had died a short time before in penury and distress, having been deprived of his means of subsistence by the fanatical people who for a time obtained the ascendency in the English church.

On the Restoration a proper regard was had for Pearson's eminent merits as a rational divine and diligent preacher. He was created doctor of divinity by the king's mandamus, made a prebendary of Ely, archdeacon of Surrey, and finally, master of Jesus College, Cambridge. All this was accomplished before the end of the year 1660, in which the king was restored. In 1661 he was appointed Lady Margaret's professor of divinity, and in 1662 master of Trinity College, Cambridge. In 1672 he succeeded Wilkins in the bishopric of Chester. He died at Chester, July 16, 1686.

The 'Exposition of the Creed' is the work by which Bishop Pearson is chiefly remembered, which has not only been reprinted, but abridged by various persons. Besides this work, he is the author of a 'Vindication of the Epistles of St. Ignatius,' and of 'Dissertations on the Rise and Succession of the early Bishops of Rome.' The last was a posthumous publication, which also contains the 'Annales Paulini,' a critical dissertation on the series of events in the life of St. Paul.

PEARSON, EDWARD, D.D., born about 1760, died 1811, a divine of the church of England, who, if his life had continued a few years longer, would probably have attained to one of the higher dignities in that church. As it is, it is as having well discharged himself of various duties in the University of Cambridge, to which he belonged, and of the duties of a parish priest at Rempston in Nottinghamshire, where he was rector, and having had by his writings no small influence in the church, that we have here to speak of him. He was a native of Ipswich, educated at Cambridge, where he was for awhile fellow and tutor of Sidney College, and afterwards master, and elected the Christian Advocate in 1809. Beside numerous single sermons preached by him on public occasions, Dr. Pearson was the author of a volume of thirteen Sermons addressed to Academic Youth, delivered by him in St. Mary's Church, Cambridge. He published also a 'Collection of Prayers for the use of Families,' and various tracts in divinity not professedly controversial. But his fame chiefly rests on his controversial writings against antagonists of two very opposite descriptions. There are two treatises of his against those who adopt Dr. Paley's views on the general theory of moral obligation and those who follow him in some of the practical conclusions to which that celebrated divine and moralist conducts his readers. These treatises excited, when first published, great attention, and well deserve to be read by all in connection with the very popular and on the whole very excellent treatise on 'Moral and Political

Philosophy' to which they relate. On the other side, Dr. Pearson was among the first to sound an alarm respecting the danger to which the church was exposed by the spread in it of Calvinistic views of the Christian doctrine. On this subject he published various tracts at the beginning of the present century, several of which were expressly directed against Mr. Simeon, who was the great maintainer of Calvinism in the university to which Dr. Pearson belonged. In fact, he stood forth the champion of the Arminian clergy in the church, and the champion at the same time of the church itself against whatever seemed to threaten its integrity and its perpetuity.

It seems unnecessary to give the titles of a long list of writings in divinity; but it may be useful to say that a complete list, arranged chronologically, may be seen in the 'Gentleman's Magazine' for 1811, where it is also said of him that he was a good man, of gentle and benevolent manners, kind and charitable, easy and pleasant in conversation, modest, unassuming, much respected, and beloved. He died on August 17, 1811.

PEAT is a substance of vegetable origin, found wherever the soil has been long soaked with water which has no outlet and does not completely evaporate by the heat of the sun.

When dried peat is examined, it is found to consist of roots and fibres in every stage of decomposition, from the natural wood to the completely black vegetable mould. From the nature of its formation under the surface of water, it acquires a portion of tannin, which has the property of preserving animal and vegetable matter from decomposition. Hence large branches and trunks of trees are found imbedded in peat, which have no mark of decomposition, except what may have taken place before the wood was completely immersed in the peat. Peat contains all the elements of the richest manure, and may by an easy process be converted into humus: for this purpose the agency of alkalis is the most effectual. If the tannin be decomposed, that of the vegetable fibre will go on, and soluble humus will be formed. When peat is newly dug up, if caustic lime be added to it before it is dry, the moisture of the peat slakes the lime, which acts on the gallic acid in the peat and neutralises it. If this mixture be then excited to fermentation by the addition of animal matter, such as urine or dung, oxygen is absorbed and carbonic acid evolved; and the residue is converted into an excellent manure, containing much soluble humus. The same may be effected more slowly by mixing peat with clay or marl, and allowing the mixture to remain exposed to the atmosphere for a considerable time, frequently turning it. But nothing accelerates this process like the addition of putrescent animal matter, which acts as a ferment and greatly hastens the decomposition.

The soils for which peat forms the best manure are the chalky and clayey. Sand has too little tenacity; it lets the gasses produced by the decomposition escape, instead of attracting them, as clay and chalk do, and preventing their escape.

The burning of peat destroys the vegetable matter and leaves the earths and salts behind. They are accordingly very strong stimulants to vegetation, especially that of clovers and herbaceous plants, of which the leaves and stems are the most valuable parts. If the soil is well furnished with vegetable matter, and capable of bringing an abundance of seed to perfection, it may be very useful to apply stimulating manures, such as peat ashes, to increase the verdure; but on poor soils destitute of humus, the increase of the stems and leaves does not ensure a proportionate increase of seed. Hence it is often remarked that soot, potash, saltpetre, and similar substances produce a deceitful growth, giving a rank green leaf, which is not succeeded by a heavy ear; but, on the contrary, the produce in seed is rather diminished than increased by the use of the manure. Whenever a stimulating manure is used, the soil should be naturally rich, or enriching manure should be applied at the same time. It is of no use to whip a horse which has had no corn and is half starved; and land which is exhausted cannot be made productive by applying lime or ashes, or saline substances, which in a richer soil abounding in humus would have excited the most vigorous vegetation.

The following particulars of the conversion of peat into a rich compost were given by Lord Meadowbank about forty years ago, and show that the principles which we have here laid down were known to him.

He recommends taking the peat out of the moss some time before it is used, that it may lose a portion of its moisture, and be lighter to carry. It is then to be carted to a dry spot, where the compost heap is to be formed. A bottom of peat is to be laid six inches deep and fifteen feet wide; on this are to be put ten inches of good yard-dung, then six inches more peat, and over this four inches of dung, and so alternately to the height of four or five feet. The whole should then be enclosed all round with a wall of peat, and covered with the same material. The proportion of the dung is about seven cart-loads to twenty-one of peat, if the weather is mild; but more dung is required if the weather is cold: over this heap ashes or lime may now be spread, in the proportion of a cart-load to twenty-eight of the compost. The dung should not have fermented much before it is used, and if it is watered with urine or the drainings of a dunghill, the effect will be more rapid. Animal matter, such as the refuse of slaughter-houses, and every substance which will readily undergo the putrefactive fermentation, will accelerate the process, and save dung in the compost. Where pigeons'-dung can be procured, a much smaller quantity will produce the desired effect. The heap should not be pressed down, but left to settle by its own weight. If the heat produced by the fermentation is very great, the whole heap may be turned over and more peat added to it. This will keep up the heat till the whole is reduced to a uniform mass of black mould. It may then be put on the land in the same quantity that farm-yard dung would have been, and consequently, by a little labour, four times the quantity of manure is produced by the mixture of the peat with the dung. It is found that lime is not essential to the formation of this compost. The fermentation excited is sufficient to decompose the tannin and convert it into a soluble extract. The fibres, partially decomposed, are reduced to vegetable mould, and the whole assumes a uniform and dark appearance. A complete chemical change has taken place, and the peat, from being very inflammable, is now scarcely capable of combustion, and that only in a very great heat. There is no better or more economical mode of converting peat into a rich manure. In summer the whole process may be completed in eight or ten weeks; in winter it takes a longer time; and it may be useful to give the heap an occasional lining of fresh dung, as is done with hotbeds in gardens to renew the heat.

Where a great extent of peat-moss renders the improvement of it desirable there are various ways in which it may be reclaimed. In some places the peat has been removed, and the loam which lay below it was found of a very fertile nature. This could only be done on the banks of rivers, into which the peat was floated by means of small canals dug through it, and communicating with the river. In all other cases the mode adopted has been that of draining and consolidating. In draining a peat-moss the water must not be let off too rapidly, for in that case the surface may become so loose and dry, that no vegetation can take place in it. If the water is drained off so as to leave two feet of peat dry above its level, this is all that is required for a beginning. The best improvement, and the most rapid, is produced by bringing sand or gravel in sufficient quantity to cover the surface with two or three inches of it. This will make a beginning of a soil, in which potatoes may be planted. At first the surface will not bear the wheels of a cart nor the tread of a horse; but in a short time a solid crust will be formed, which will increase in strength and thickness as cultivation advances. There are many fine pastures in Scotland which once were bare peat-mosses, on which it would have been dangerous for a man to walk, but which now bear heavy oxen, and seem as solid as any pasture on a clay subsoil. Manuring and liming are the most effective operations in bringing about this great improvement. Potatoes and oats are usually the first crops on reclaimed peat-mosses. It is long before they become capable of bearing wheat; nor is this crop to be recommended at any time, unless there be a good depth of soil formed over the peat. Laying down to grass as soon as a certain degree of improvement has been made, and pasturing with sheep at first and cattle afterwards, tend more than any other means to consolidate the surface and deepen the mould, which gradually increases by the decomposition of the tannin in the peat.

A patent has been lately obtained by Mr. W[illegible], managing director of the Dublin Steam Navigation Company, for compressing peat into a dense mass, so as t eable coal. It is said to be superior to coal in its properties of producing heat by combustion, forming an excellent charcoal or coke. It is asserted that this charcoal is much more combustible than that of wood, and very useful in the manufacture of fire-works. Mr. Williams has found that with 10 cwts. of pit-coal and 2½ cwts. of his factitious coal, the same quantity of steam can be generated as with 17½ cwts. of pit-coal alone.

The process is as follows:—Immediately after being dug it is triturated under revolving edge-wheels faced with iron plates perforated all over the surface, and is forced by the pressure through these apertures, till it becomes a species of pap, which is freed from the greater part of its moisture by a hydraulic press. It is then dried, and converted into coke in the same manner as is done with pit coal. The factitious coal of Mr. Williams is made by incorporating pitch or resin melted in a cauldron with as much of the peat-charcoal ground to powder as will form a tough doughy mass, which is then moulded into bricks. (Dr. Ure's *Dictionary of Arts and Manufactures.*)

The use of peat for fuel is too well known to require notice, but it may be interesting to know how peat is made in Holland, where it cannot be dug out of the solid mass, but is brought up in the form of mud from a considerable depth under water. It is raised by means of small strong nets fixed by an iron ring to a long pole, in the manner in which canals are cleared of mud. This liquid peat is brought in boats to a place prepared for its manufacture, which has been levelled as a brick-yard usually is. The soft mud is spread over this to the depth of six inches, and the water is allowed to drain off slowly: when the peat begins to dry, men fix boards to their feet and walk over it, so as to compress it; and as soon as it will bear cutting, it is cut with a spade made on purpose into oblong pieces of the usual size of peat, which is about eight or nine inches long and five wide; the treading and drying have reduced the thickness to about four or five inches. When tolerably solid, these peats are set on edge, and afterwards stacked loosely, so that the air may pass through them. In some places they have sheds for the purpose of protecting them from rain. They soon become very hard, and burn more like wood or coal than the peat which is cut immediately from a solid mass. They give a very great heat, and form a coal which, when it is shut up in a close vessel to stop the combustion, and allowed to cool, has a considerable resemblance to charcoal. The ashes of this peat contain very little earth, and are very light and white. They are abundantly used as a top-dressing for grass and clover on light lands, and for this purpose are extensively exported to the sandy districts in Guelderland and Flanders. They are not so much prized for stiff soils. Dutch peat is used as fuel for all the purposes of manufactures, except for the forging of iron, for which coals are imported from England and the Netherlands. The peat-bogs in Holland begin to be exhausted, and the fuel is so dear, that it is found more economical to import coals from England, which are used chiefly in cast-iron stoves.

PECCARY. [Swine.]

PECCHIO, GIUSEPPE, born at Milan in 1785, studied at the college of [illegible] under the well-known Father Soave, and afterwards proceeded to Pavia to study the law. After taking his degree in that university, he returned to Milan, and in 1810 was appointed assistant counsellor of state for the departments of finances and the interior of the kingdom of Italy. In 1814 he lost his situation, in consequence of the Austrian occupation of Lombardy, a circumstance which gave occasion to his work entitled 'Saggio Storico sulla Amministrazione Finanziera dell' ex-Regno d'Italia dal 1802 al 1814,' which is a useful book of reference for the history and statistics of that kingdom. In 1819 he was appointed deputy to the Congregazione, or provincial assembly of Milan. In 1821, being seriously implicated in the attempt at an insurrection against the Austrian government, he was obliged to emigrate. He first went to Switzerland, and from that country to Spain, which was then making a second experiment of a constitutional government. Pecchio had thus an opportunity of observing the national character and the spirit of the various political parties. His observations on Spain are in the shape of letters, and published under the following title: 'Sei Mesi in Spagna nel 1821.' In 1822 he proceeded to Portugal, where the same passions and parties were at work, and he likewise recorded the impressions which he received in that country in another series of letters: 'Lettere à Lady G. O. dal Portogallo.' Like his predecessors Baretti, Alfieri, Byron, and others, he was struck with the inferiority of the Portuguese as a people to their Spanish neighbours. Returning to Spain, he visited the southern provinces of that kingdom, and was at Cadiz at the fall of the constitutional government in the summer of 1823. He then embarked at Cadiz for England, where he met several Italian friends and brother emigrants. In 1825 he was appointed, together with Count Gamba, by the Philhellenic Committee to convey to Greece the sum of 50,000*l.*, the fruits of a loan made for the Greeks. Having executed his commission at Nauplia, Pecchio visited Smyrna, from whence he embarked for England. In his short stay in the Levant, Pecchio found time to make and record his observations, as he had done in Spain and Portugal. That was a critical period for the Greek cause, as the Egyptians under Ibrahim were carrying everything before them in the Morea. Pecchio's account of the affairs of Greece was published in English, with that of other contemporary travellers: 'A Picture of Greece in 1825, as exhibited in the Narratives of James Emmerson, Joseph Pecchio, and W. H. Humphreys,' 2 vols. 8vo. The book was translated into French and German. Pecchio's account was afterwards published separately in the original Italian: 'Relazione degli Avvenimenti della Grecia.'

On his return to England, towards the end of 1825, Pecchio repaired to Nottingham, where he gave lessons in the modern languages, and he afterwards removed to an academy at York in the same capacity. Towards the end of 1829 he married an English lady of property, and went to reside with her at Brighton. He remained for seven or eight years in Brighton, where he wrote several works, in which he embodied his remarks upon England and the English. These remarks are expressed in a spirit of fairness and discrimination rarely found in the accounts of England by foreign writers.

Pecchio was an observer, and he was also happy-tempered and lively, a pleasant companion, and a man of the world. He came to England with prejudices against the country, but he took pains to study it, and became strongly attached to it. 'Brought up in the school of Napoleon,' he says of himself, 'dazzled by the splendour of his triumphal car and the trophies of his half hundred victories, seduced by the benefits which he had imparted to my own country, I harboured in my heart for many years a feeling of hostility to England, before I had an opportunity of knowing and studying the country.' (*L'Anno mille ottocento ventisei dell' Inghilterra*, the last paragraph.) And he observes, in the same work, that the Italian writers of the last century, Baretti, Algarotti, Genovesi, Filangieri, Alfieri, and others, were all admirers of England, but that during twenty years of war the sentiments of the Italians towards that country became changed rather through the influence of French opinions than from national animosity. The absolute government of Napoleon had succeeded in instilling into the rising generation a feeling of dislike to England as a part of their education. By daily repeating the words 'enemies of the Continent,' 'tyrants of the sea,' 'monopolists,' 'grasping shopkeepers,' 'pirates,' &c., the French persuaded themselves, as well as their Italian and other neighbours, that there was something monstrously horrible in the existence of England as a nation. Even men of abilities, such as Botta, Gioia, Monti, and others adopted the common prejudice, 'because they had not studied English history, and had not weighed in even scales the good and the evil that England had done to the rest of mankind, and compared them with the good and the evil that other nations had also done.' To his friend Ugoni, who invited Pecchio after his marriage to go and reside in France, he answered, 'I should become doubly rich in France as regards my income, but I should be poorer in peace of mind; I should lose that sentiment of security which I feel in this strong island, and I should miss the courteous hospitality and the equanimity of English life, which are to me a full compensation for the unpleasantness of the climate. . . . Even the view of the neighbouring cemetery in which I shall be buried some day is pleasant to me.' (Ugoni, *Vita e Scritti di Giuseppe Pecchio*, Paris, 1836, p. 36.) When he wrote this, Pecchio had been for some time suffering from a disease of the chest, which terminated his life in June, 1835. His death was calm and resigned, and he was buried in the parish churchyard of Hove near Brighton.

Besides the works already mentioned, Pecchio wrote:—

1, 'Osservazioni semi-serie di un Esule sull' Inghilterra,' being a series of sketches of English habits and manners, each sketch forming a separate chapter, and showing the shadows as well as the lights of English life. The sketches are true, humorous, and interesting. Many things strike a foreigner which appear commonplace to a native, but even a native may learn from Pecchio's book to form a more just estimate of his own country. Among other sketches, those of the Country Markets, the Sailors at Wapping, the Betrothed, the Young Ladies of England, and the Roads, deserve notice. In a chapter entitled 'England the Refuge of the Oppressed' he describes with much humour the curious mixture of emigrants of all countries whom he saw in London in 1823. 2, 'Storia della Economia pubblica in Italia,' 8vo., Lugano, 1829. This is perhaps the most important of Pecchio's works. A collection of the Italian economists was made by Custodi, which fills about fifty volumes. Pecchio has taken the principal of those writers in order of time, and has given a short but clear abstract of the works of each. He has added, first, an introduction on the progress of political knowledge in Italy; second, at the end of the work a comparison between the English and the Italian writers on political economy; and third, a statement of the improvements effected in the various Italian states during the eighteenth century, in consequence of the writings of the economists. A more full account of this book is given under POLITICAL ECONOMY. 3, 'Una Elezione di Membri del Parlamento in Inghilterra,' in which he describes a contested election at Nottingham in 1826. Like all Pecchio's sketches, it is true, vivid, and entertaining. 4, 'Vita di Ugo Foscolo.' This biography has been noticed under FOSCOLO. 5, 'Storia Critica della Poesia Inglese,' 4 vols. 12mo., 1834, which he left unfinished; besides other minor works, which are noticed in his biography by Ugoni.

PECK, a measure of two gallons, or the fourth part of a bushel. [BUSHEL.] It is used as a measure of dry goods only.

PECK, FRANCIS, a learned and industrious antiquary, was born at Stamford in Lincolnshire, May 4, 1692; and was educated in his native town. He afterwards went to Trinity College, Cambridge, where he took the degree of B.A. in 1715, and M A. in 1727. In 1723 he was presented to the rectory of Godeby Maureward in Leicestershire; and in 1736 he received a prebendal stall in the cathedral of Lincoln. His principal works were:—1, 'The Antiquarian Annals of Stamford, in Lincoln, Rutland, and Northampton Shires,' fol., London, 1727. 2, 'Desiderata Curiosa,' the first volume of which was printed in folio, London, 1732, followed by the second in 1735, both reprinted in 4to. in 1779. 3, 'A Catalogue of all the Discourses written both for and against Popery in the time of King James II.,' 4to., London, 1735. 4, 'New Memoirs of the Life and Poetical Works of Mr. John Milton,' 4to., London, 1740. And 5, 'Memoirs of the Life and Actions of Oliver Cromwell,' 4to., London, 1740. Besides these he published several sermons and poems, and, in 1742, his last work, a volume of religious discourses. He contemplated various other works, some of which appear to have been completed, but none were ever made public. Among his manuscripts, the greater part of which became the property of Sir Thomas Cave, Bart., were five volumes in 4to. fairly transcribed for the press, entitled 'Monasticon Anglicanum' These are now deposited in the British Museum. Mr. Peck concluded a laborious and useful life, July 9, 1743, and was buried in his church of Godeby.

(Nichols *Lit. Anecd. of the Eighteenth Century*, vol. i., p. 507-521; Chalmers's *Biograph. Dic.*, vol. xxiv., 235-240.)

PE'CORA, the name given by Linnæus to his fifth order of MAMMALIA, and thus defined by him in the *Systema Naturæ*:—

Lower *incisors* (dentes primores) numerous; no upper incisors. *Feet* hoofed, bisulcate. *Food* by plucking up (evellendo) plants to be ruminated. Ventricules 4: the *Rumen* for macerating and ruminating; the *Reticulum* cancellated and recipient; the *Omasus* manifolded and consuming; the *Abomasus* banded, ascescent, &c.

In the body of the work the definition is—

No upper *incisors* (*dentes primores*): six or eight lower incisors, very remote from the molars. *Feet* hoofed. *Mammæ* inguinal. The genera composing the order are *Camelus*, *Moschus*, *Cervus*, *Capra*, *Ovis*, and *Bos*. The Pecora stand between the orders *Glires* and *Belluæ*. [RUMINANTS.]

PECQUET, JEAN, was born at Dieppe in 1622. He studied medicine at Montpellier; and while a pupil there, in 1647, he made the discovery, for which he is chiefly celebrated, of the receptaculum chyli and the thoracic duct. [ABSORPTION; LYMPHATICS.] He afterwards went to Paris, and continued his researches on the lymphatic system, and showed that the lacteals do not, as had been imagined, terminate in the absorbent glands, or the liver, or the spleen, but in the receptacle which he had discovered; and that their fluid is thence transmitted by the thoracic duct to the left subclavian vein. His discovery may be said to have put an end to the idea long entertained, that the blood was formed in the liver, and to have added important confirmation of the Harveian account of the circulation. Pecquet died in 1674.

PECTEN (Malacology). [PECTINIDÆ.]

PECTIC ACID. PECTIN. The jelly of certain fruits, as the currant, gooseberry, &c., is distinguished from gelatin, or animal jelly, in containing no azote. Pectic acid was first obtained by Braconnot, so named by him from the Greek *pectis* (πηκτις); and whenever pectin is treated with an alkali, pectic acid is formed. As these substances are intimately connected, they may be considered together.

Pectin may be obtained from many fruits by carefully expressing their juice, and evaporating it at a temperature not above 212°. It may also be procured by adding alcohol to recently expressed currant or gooseberry juice; in a few hours a gelatinous substance separates, which is to be washed with weak alcohol and then dried: in this state it resembles isinglass in appearance, and when immersed in cold water it swells like starch.

Another method has been given for preparing pectin, which is that of mixing the clear expressed juice of currants with that of sour cherries, when pectin falls down; the liquid being poured off, the pectin is to be washed with cold water as long as it comes away coloured.

Hot water has less action upon dry pectin than cold water has: in dilute and boiling alcohol it dissolves slightly; the solution however is not very adhesive. Pectin has no acid properties, nor does it render iodine blue like starch When pectin is treated with nitric acid, it yields oxalic acid and mucic acid, accompanied with a trace of a bitter yellow matter: hydrochloric acid is rendered of a fine red colour by it when they are heated together, and red flakes separate, which are not soluble in ammonia. Pectin has also been found in the bark of most trees.

Pectic acid is obtained whenever carbonate of potash is added to pectin, but carbonate of soda does not produce this effect, nor does ammonia. Lime-water however partially converts pectin into pectic acid.

Pectic acid is perhaps most conveniently obtained from the carrot; for this purpose the rasped root is to be washed with water, and pressed, till it ceases to dissolve anything; then 100 parts of the pressed carrot are to be boiled in water with five parts of bicarbonate of potash; the root is to be again pressed, and the clear solution, which is pectate of potash, is to be decomposed by the addition of a solution of chloride of calcium, which yields by double decomposition an insoluble pectate of lime: this is to be treated with dilute hydrochloric acid, which separates the pectic acid.

Pectic acid has the following properties: it is a colourless jelly, slightly acid, and reddens litmus paper very distinctly. When distilled, it yields a product containing much empyreumatic oil, but no trace whatever of ammonia.

It is very little soluble in water, whether hot or cold, and the filtered solution acts less powerfully on litmus than the gelatinous acid. Although it contains so little of the acid, yet the solution becomes gelatinous when alcohol or sugar is added to it; lime or barytes water also occasions precipitation in it.

When gelatinous pectic acid is gently heated with an excess of caustic potash or soda in a platina crucible, a brown-coloured solution is soon obtained; and when thus evaporated to dryness, the pectic acid is found almost entirely converted into oxalic acid.

The neutral pectates of potash, soda, and ammonia, when dissolved in water, are separated in a gelatinous state from solution by alcohol, sugar, and saline solutions, &c.

Pectic acid is decomposed by sulphuric acid when they are heated together, and nitric acid converts it into mucic oxalic acid, &c. Most of the stronger or mineral acids can decompose the saline compounds of pectic acid; but this is not the case with the greater number of the vegetable acids.

According to Dr. Thomson, pectic acid is composed of—

Eleven equivalents of carbon . .	66
Seven equivalents of hydrogen . .	7
Ten equivalents of oxygen . .	80
Equivalent . .	153

PECTINA'RIA, Lamarck's name for a genus of *Amphitritæ*, Cuvier's fourth family of his *Annélides Tubicoles*, the first order of his *Annelides*. The *Amphitritidæ* of Lamarck form the third family of his division of *Sedentary Annelids*, the others being the *Dorsalidæ*, the *Maldanidæ*, and the *Serpulidæ*. Lamarck's *Amphitritidæ* contain the genera *Pectinaria*, *Sabellaria*, *Terebella*, and *Amphitrite*.

Generic Character.—Body tubular, sub-cylindrical, attenuated posteriorly, having on each side a row of setiferous nipple-like appendages; the filaments short and fasciculated. The anterior part wide, truncate, oblique, with two combs (pectines) of golden spangles (paillettes) which are very brilliant and transverse. Mouth elongated, bilabiated, surrounded with short and numerous tentacles. Four pectinated branchiæ, situated externally on the second and third segment of the body. Tube a reversed cone, membranous or papyraceous, arenaceous, not fixed. (Lam.)

Cuvier states that their intestine, which is very ample and folded upon itself many times, is ordinarily filled with sand.

Locality.—The sea-coasts of temperate and warm climates.

Example, *Pectinaria Belgica*. Seas of Europe.

Lamarck's *Pectinariæ* are the *Amphictenes* of Savigny, the *Chrysodons* of Oken, and the *Cistenes* of Leach, according to Cuvier, who animadverts, not without justice, on these perpetual changes of names, which, he remarks, are likely to end in rendering the study of nomenclature more difficult than that of facts.

PECTINIBRANCHIATA, Cuvier's *sixth* order of Gastropods. The sexes are separate. The respiratory organs consist nearly always of branchiæ composed of *lamellæ* united in the form of combs, and are concealed in a dorsal cavity widely opened above the head. The *Pectinibranchiata* are nearly all furnished with turbinated shells, the aperture of which is sometimes entire, sometimes notched, sometimes canaliculated, and most frequently capable of being more or less closed by an operculum attached to the foot of the animal posteriorly.

This order forms the most numerous division of gastropods, comprehending nearly the whole of the spiral univalves, and many with shells simply conical. Their branchiæ, composed of numerous leaflets or fringes ranged in parallel order like the teeth of a comb, are attached, on one, two, or three lines (according to the genus), to the ceiling (plafond) of the pulmonary cavity, and which opens by a great solution of continuity between the edge of the mantle and the body. Two genera only, *Cyclostoma* and *Helicina*, have, in lieu of branchiæ, a vascular network covering the plafond of a cavity in other respects similar; these are the only genera that respire air directly; all the others respire water.

All the *Pectinibranchiata* have two tentacles, and two eyes, carried sometimes on particular pedicles, and a mouth in the form of a proboscis more or less elongated. The intromittent organ of the male, attached to the right side of the neck, cannot in general be retracted into the body, but is bent back in the branchial cavity, and is sometimes very large. (ENTOMOSTOMATA, vol. ix., *Buccinum*, p. 455.) *Paludina* alone is able to retract it into a special cavity through an orifice pierced at its right tentacle. The rectum and the oviduct of the female creep also along the right side of this cavity, and between them and the branchiæ is a particular organ composed of cellules secreting a very viscous humour, serving to form a common envelope which encloses the eggs, and which the animal deposits with them. The forms of this envelope or nidus are often very complicated and very singular.

Their tongue is armed with small hooks, and wears down the hardest bodies by time and repeated friction.

The greatest difference between these animals consists in the presence or absence of the canal formed by the prolongation of the edge of the pulmonary cavity of the left side, and which is carried out by a similar canal, or by a notch in the shell, to enable the animal to respire without quitting its shelter. There is also this distinction between the genera, that some are without an operculum: the species too differ from each other by the filaments, fringes, and other ornaments which they carry on their head, their foot, or their mantle. (Cuvier.) For an enumeration of the families and genera composing the order, see MALACOLOGY, vol. xiv., p. 317.

PECTI'NIDÆ. Before we enter upon the detail of the genera which it is our intention to notice under this head, it will be necessary to lead the student to an inquiry as to the organization of the forms composing the tribe. A common oyster is within the reach of every one, and a scallop may be procured by most; but till some knowledge of the soft parts contained within the shells is obtained, the observer sees only a gelatinous mass fringed with the gills, or what is vulgarly termed the beard. A general view of the organization of the *Pectinidæ* will be found in the article CONCHIFERA; and we now proceed to a more minute examination of the structure of these Monomyarians.

'Where constant action is not necessary,' remarks John Hunter, in his treatise *On the Blood*, 'muscles alone are employed, as in the greater number of moving parts in most animals; and where any position is required to be constant, and the motion only occasional, from being seldom wanted, there elasticity is alone employed for the purpose of constant position, and muscles for the occasional action. Some bivalves (as the oyster) have a strong muscle passing between the shells for closing them occasionally; but for opening them no muscles are made use of, as this is performed by an elastic ligament in the joint of the two shells, which is squeezed, when shut, by the contraction of the muscle; and when the muscle ceases to contract, the elasticity of the ligament expands it, so that the shell is opened.'

By this simple but beautiful contrivance the open state of the shell, which is necessary for the collection of food and the purposes of respiration, &c., becomes to the animal a condition of repose. In the museum of the Royal College of Surgeons in London (*Physiological Series*) this adaptation is well seen. No. 55 is the longitudinal section of the valves of an oyster, to show the adductor muscle and its antagonist the elastic ligament at the hinge, as above described by Hunter. (*Cat.*, vol. i.)

The following experiment is recorded by Sir Anthony Carlisle. In a pair of fresh oyster-shells, weighing 2465 grains, the entire elastic ligament or spring of the hinge weighed three grains and a half; the elastic power of this spring was equal to the pressure of three pounds fifteen ounces avoirdupois when placed upon the centre of the flat valve, and confined to the area of the insertion of the valvular muscle. (*Hunterian Oration*, 1826.)

No. 673 (of the series in the museum above quoted) exhibits the soft parts of a Scallop (*Pecten maximus*, Linn.), from which the left lobe of the mantle and the corresponding gills and labial tentacles have been removed to show the alimentary canal. The stomach, which is laid open, exposes the apertures by which the bile enters. The intestine may be traced through the projecting mass of ova to the apex of that part, where it suddenly returns upon itself; then winding round the great adductor muscle, it terminates opposite the posterior extremities of the branchiæ. A bristle is inserted in the anus.

The respiratory apparatus, together with other organs, is very well illustrated in No. 959, which exhibits the soft parts of a Scallop (*Pecten maximus*, Linn.) injected. The right mantle-lobe is reflected to expose the branchiæ, which are seen protected by the mantle on the opposite side. The branchial membrane is very delicate in this species, and is supported by numerous slender horny filaments, along which the branchial vessels pass. The branchiæ are placed near the circumference of the shell, and currents of sea-water are perpetually driven over and through them by the ciliary vibrations, aided by the action of the shell and mantle. The large foot of this species is placed between the branchiæ, which are four in number, two on each side. A thick bristle is inserted at the mouth and a smaller one at the opposite side of the digestive canal. No. 960 is a similar injected specimen, but with the right mantle-lobe wholly removed, to show the branchiæ of that side and their supporting membrane. This is broadest at the posterior and of the branchiæ, and terminates in a point anteriorly, where the branchiæ are lost between the two labial membranes. (*Cat.*)

Mr. Garner considers the foot of *Pecten*, &c., to be an organ for the prehension of the food, collected by the vibratile currents near the mouth. It has but one slender muscle. The same author observes that it is evident that in the *Pecten* the labial ganglia are compound; and he states that the excretory organs throw off mucus and colouring matter as well as carbonate of lime, which last is often found in them in the form of concretions; also uric acid. In the *Pecten* a minute orifice leads directly on each side into them. The oviducts likewise enter them. Above, each excretory sac leads into a single transverse cavity under the pericardium. The orifice of the excretory organs is generally near the posterior muscle, and the oviduct more anterior. The ova are discharged into the excretory organs. In the *Oyster* the vessels do not seem to form a gland, but throw off from their extremities distributed to the mantle the calcareous matter to the valves. Garner further observes that those *Lamellibranchiata*, which, like the common mussel, are exposed on the bare rocks to the action of the sun and air, have the valves fitting to each other most exactly, preventing all evaporation. When the valves are open at any part, the animal either inhabits deep water, as many species of *Pecten*, or has the power of burrowing in the mud or sand when left dry by the ebb of the tide.

No. 1388 in the Museum of the Royal College of Surgeons is prepared principally to exhibit the organ of touch. It consists of the soft parts of a *Pecten maximus* minutely injected. The left lobe of the mantle and corresponding branchiæ have been removed, showing the fleshy organ which protrudes from the abdominal surface (the foot). This terminates in an expanded disk, which is an organ of adhesion, and subservient to motion as well as touch. Numerous small tentacles or feelers are arranged along the thickened margin of the mantle; and the sense of touch is further exercised by the highly vascular fimbriated processes which extend from each side of the mouth, and are called the lips. The situation of these lips is indicated by a bristle placed in the mouth. (*Cat*, vol. iii.)

A series of highly-finished figures illustrate the organization of *Pecten* in Mr. Garner's memoir, above alluded to, in the second volume of the 'Transactions of the Zoological Society of London' (pl. xix.). Fig. 1 shows the animal of *Pecten opercularis*, the left valve removed, and the mantle turned up. All the parts are most clearly indicated by the letters of reference, and the eye-specks noticed in the article *Conchifera* are well shown in fig. 1. The stomach, intestine, liver, ovary, &c., of *Pecten maximus* are exhibited in fig. 2. Fig. 3 is one of the ocelli, or eye-specks, found on the margin of the mantle of the same, with its optic nerve magnified; and in fig. 4 all the blood-vessels of *Pecten maximus*, excepting a set of large veins, situated upon the muscle, into which the veins, which are truncated in the figure, enter, are beautifully displayed.

The organization of the oyster is altogether lower than that of the *Pecten*. In the former we miss the well-developed foot, nor is there any trace of eye-specks. 'The shelly case of the oyster,' observes Sir Anthony Carlisle, in his eloquent oration above alluded to, 'is its sole security, and a superior delicacy of touch, diffused over the whole of the living surfaces, warns the creature of every danger, and bids the closing of the senseless valves. The inward organization is equally simple with the exterior forms, and both are suited to a passive life; for locomotive beings demand evidences of distant things,—sometimes to supply their wants, and on other occasions to inform them of danger; but a stationary creature, being doomed to rely on its fixed resources, would only be tantalised by evidences placed beyond its control.' Sir Anthony has described the organization of the soft parts in so lucid a manner, that his description will be understood by any one who feels an interest in the subject, and will follow it with the animal before him. This description we proceed to lay before the reader in the words of the lecturer, as being more adapted to convey clear ideas than any we could substitute.

'The oyster animal,' says Sir Anthony Carlisle, 'is attached to its shells by a very conspicuous mass of muscle and tendinous ligament, which adheres to the centres of the insides of the shells;* and around this middle substance all the other living parts are affixed. Between the muscular ligament and the hinge of the shells, the chief bulk of the body is situate; it occupies the great concavity of the under valve, presenting a squared margin opposite to the hinge, and a projecting margin along its two sides,—the surfaces of the body, which are placed in contact with the shells, present a lace-work of fat, when the animal is in good condition, resembling that of the omentum in quadrupeds. The marginal borders, proceeding alike from the upper and the under surfaces of the body, are gradually extended as they advance toward the edges of the shells,—and they form the outline of those expanded membranes, called the *pallium* or *coverlet* (mantle), which occupy the flatted and larger portions of the shells, and fold over the water-lungs, termed *branchiæ* or *gills*. As there are some parts of the animal and of its shells which differ on the two sides or borders, it becomes necessary to define a *right* and a *left* side. If an oyster be placed with its concave shell downward, and having the hinge next to the observer, the right and left sides will then be determined. The loose folds of the *pallium* become united on the right side, nearly opposite to the muscular ligament,—and they form an entrance to the interior of the *branchiæ*, which may be named the *branchial porch*. When the shells are expanded, the cavity of the branchial tube becomes necessarily dilated, and this occasions a rush of water into all the internal proper branchial vessels, while the outer surfaces of those gills are floated in fresh supplies of water at each opening and closing of the shells. This simple and effective mechanism of these water-bellows is like the other all-wise providings of Omnipotence.'

'At the upper squared end of the body, the marginal borders appear to be glandular, and these, together with a middle follicle, seem appointed to form the elastic ligament or spring of the hinge. The two angles of this end of the oyster are slightly attached to both the upper and under shells, by the upper and under surfaces of these angular extremities; but those adhesions are not muscular, they are merely close contacts, and only occasionally used to make the glandular parts touch the elastic ligament of the hinge. At the upper end of the body, and on its left side, the marginal borders are more extended than upon the opposite or right side, and the top of this border forms a hood over the mouth, where two pairs of leaf like lips are placed, so as to direct the casually presented food into the throat. The marginal borders on the left sides descend to form the *pallium*, and they meet and coalesce with those from the right sides at the *branchial porch*. In the middle, between the folds of the pallium on the right side, and in contact with the central muscle, the terminal intestine descends, and its opening or anus is situate at the entrance of the branchial porch.

'The *branchiæ*, or proper gills, consist of four equal-sized folds, enclosed by the pallium. These branchiæ extend from between the palpi, or lips of the mouth, on the left side, to the junctions of the pallium, on the right side, where it forms the branchial porch. The roots of these gills are joined to the insertions of the pallium, where its two folds adhere to the central tendon, and by this structure a large branchial cavity is formed, into which the smaller branchial tubes open by four distinct rows of holes, each of them allotted to one plait of the gills. When any liquid is forced into the branchial cavity, it spirts out at numerous distinct pores along the convex edges of the gills, and these pores severally correspond with the single tube assigned to each plait of the branchiæ,—so that the inspired water passes from the branchial cavity straight through the tubes of the gills into the open space between the folds of the pallium, without returning. This water respiration is probably a chemical action upon the elements of water itself, and not an abstraction of air, because oysters and such-like animals often reside at extreme depths in the sea, where the pressure upon gaseous matter would be a physical obstacle.'

'The heart of the oyster is seated within a free space which is bounded by an arch of the body, formed between the great valvular muscle and the mass which is occupied by the liver and stomach. Two remarkable circumstances belong to this heart:—its contained fluid or blood does not coagulate spontaneously, and it holds in solution the same proportion of sea salt with the surrounding water. The muscular flesh of the ventricle of the heart is soft and tender, like that of an incubated chick in its first stage. The auricles are of a black colour throughout their tissues,

---

* See *ante*.

—a peculiarity not easy to be explained. The arterial and venous systems resemble those of the whole tribe of molluscous *Acephala*, but the singularities of each species are difficult to be traced, because the vessels are too delicate to admit gross injections, and those of more refined composition are apt to pass out of the vascular tubes, and by extravasation to spoil their distinctness.

'Within the body are the stomach and liver, occupying its principal bulk. The stomach consists of a sinuous cavity, subdivided by alternate projections and clefts, adapted to each other, and in those spaces I have generally found a detached piece of cartilage, whose office may be that of assisting in the trituration of the food, because the interior of the stomach itself presents similar cartilaginous projections. The intestine is a simple tube coiled round the stomach and the liver; it begins at the lower and left end of the stomach, and terminates at the branchial porch; it is tinged with amber coloured bile throughout its course. The liver is the most conspicuous and the largest of all the glandular organs assigned to this tribe of animals; it everywhere surrounds the stomach, and by obvious pores discharges its bile into every space of that cavity, colouring the contents of an umber-brown hue. Externally, the liver exhibits a regular series of equal-sized granules, which may be shown by boiling the animal, and then tearing off its loosened exterior covering. The inward structure presents arborescent vessels which converge into the secretory ducts as they approach the stomach. It is worthy of notice, that the minute vessels of the liver, in all these creatures assume an acinated or grape-like figure, similar to that which is common to all the higher orders of animals. Both the surface of the animal in contact with the concave and that in contact with the flat shell present similar parts, and the cavity for lodging the heart is equally exposed to the inner surface of each shell. A cone-shaped extension of the body winds along the left side of the muscular ligament; it has a tubular cavity, which communicates with the alimentary passages; it resembles the reproductive parts in the scallop and is an obscure likeness of the *foot* in some other *Acephala*.'

'Oysters are considered to be perfectly androgynous. . . . They are viviparous, and their young are found within the branchial passages, and between the folds of the coverlet, during the months of June and July, in this climate.* In the first state the oyster exhibits two semiorbicular films of transparent shell, which are constantly opening and closing at regular intervals. The whole brood are associated together, by being involved in a viscid slime, and in that state called "*The Spat*." It being common among viviparous animals of this kind to have their spawn posited in contact with the lungs, the involving slime serves as the first nutriment, and we may infer that the fœtal food, so influenced by the gills, is at the same time a respiratory supply to the imperfectly formed young.'

'The *brain* or substance principally concerned with sensibility is small in proportion to the bulk of an oyster. It consists of two minute detached nodules or ganglions, each having a few slender nervous fibrils passing in radii to the neighbouring parts; the largest ganglion is affixed to the gullet, showing that the chief preserving sense is given to test the articles of food.'

Sir Anthony Carlisle further informs us that the body of the oyster is entirely covered by one continuous membrane, which extends to the margins of the pallium, and embraces within its folds all the vessels and parts belonging to that apparatus. Several transparent arborescent blood-vessels are placed between this outer membrane and the substances of the body, and on the palpi or lips. The marginal borders of the pallium are not attached to the shells, but they occupy the whole range of their inner circumferences, and are moveable towards the edges of the shells or retractible at discretion. Two arrangements of muscle appear along the loose borders of the pallium; one set of muscular fibres form a longitudinal band of several lines in breadth, and this serves to gather up and shorten the outline of the pallium when it is retracted; the other is a series of muscles passing from the margin and radiating towards the great central muscle.

'The muscular parts of these radiated muscles,' continues Sir Anthony, 'extend a few lines within those of the longitudinal bands; they are obviously retractors, or opponents to the marginal protrusions of the pallium,—and each bundle of these muscles is attached to a small tendon. These tendons form a lace-work by lateral junctions with each other, until the whole are collected into two principal cords, which are converged together, and finally inserted into the left sides of the central muscular ligament. This plexus of tendons resembles that of the extensors of the human fingers, but their subdivisions in the oyster consist of several series, and those which are joined to the muscles are exceedingly multiplied. From observing the living oyster, it is evident that these radiated muscles are excited to contract, when touched, and that each stimulated part hauls up a tuck of the border of the pallium, and by a continuity with adjacent tendons, every touched point moves and excites similar neighbouring and allied muscles, so as to withdraw a larger portion of the pallium from annoyance. The use of all these arrangements appears to be for the protection of the living animal, since the irritable muscular borders of the pallium are not only adapted to withdraw *themselves* from hurtful impressions, but by pulling the associated tendons against the central muscle, *it* becomes likewise excited, and immediately closes the valves.'

'Along the borders of each fold of the pallium, and projecting from both edges of their margins, are two rows of papillæ, which are sometimes to be seen distended with water, and at other times they are collapsed into a fringe-like substance. In the distended state, these papillæ, or nipples, often eject water from a pore at the point of each, and then collapse. The *mesenteric portions* of the pallium are fixed to the central muscle and tendon; they each consist of two plates of the general investing membrane, and they embrace the tendons of the radiated marginal muscles. Between these membranous plates there are non-adhering spaces, like those between the *pia* and *dura mater* of the human brain, and from being occasionally found distended with water, they have been, as *I believe, falsely* called "*absorbing* vessels." These spaces appear to be truly cellular, and not continuous tubes, for they communicate with each other laterally, and thus resemble the tubular cells of the *corpus spongiosum penis*, just before they are converted into veins. The use of the cellular structure of these mesenteric membranes is, to protrude the margins of the pallium by the force and direction of injected water; for when the mesentery of the pallium is so distended, the fringed borders are pushed to the margins of the shells. This action is more directly manifested in the syphon of the *Pholas Dactylus*. A dingy green colouring matter appears irregularly dispersed through the larger convex ranges of the *fimbriæ*, and it appears to be the same as the tinging substance of the scales belonging to the upper or flat shell. Papillæ exactly similar to those of the oyster may be seen in the syphons of *Pholades*, in the *fresh-water mussel*, in *Actiniæ*, and in several other *mollusca*. The outer surfaces of the pallium are occasionally found adhering, at uncertain places, to the inside of the shells; but this adhesion depends wholly upon close contact, and it only happens where the shell is undergoing repair, or where it is augmenting; in no instance does the substance of the pallium mingle with the shelly materials. [SHELL.]

PECTENS.

Pecten. (Lamarck.)

Animal subrotund, not thick; lobes of the mantle very delicate, disunited throughout, thickened on the borders, and furnished with many rows of fleshy cilia, between which are regularly disposed a series of smooth sessile tubercles; branchiæ large, decomposed into detached filaments; the small foot dilated at its extremity; mouth rather large, oval, surrounded with projecting and deeply cut lips, and furnished on each side with a pair of triangular palpi truncated at their extremity. (Deshayes.)

Generic Character.—*Shell* free, regular, inequivalve, auriculated; lower margin transverse, straight; umbones contiguous. *Hinge* toothless; cardinal pit entirely internal, trigonal, and receiving the ligament. (Lam.)

Geographical Distribution.—The Pectens are widely diffused, and species are to be found in the seas of most climates. Though there is a general similitude in the shells of all the numerous species which at once shows to what genus the animal belongs, the varieties of form and colour are infinite, and the species are in many instances very difficult to be defined, though the eye of an acute observer will at once determine differences which the pen cannot convey without some difficulty, if it succeed in making the differences understood at all. The colours of some are most vivid and beautifully variegated, whilst those of others again are sombre. The shells of some are stout and heavy, of others light, and some are nearly as transparent as glass (*Pecten vitreus*, Gray,* and *Pecten vitreus*, King, for example). The depths at which they have been hitherto found range from the surface to twenty fathoms. *Pecten vitreus* (King), which occurred everywhere in the Strait of Magalhaens, was found attached to the leaves of *Fucus giganteus*, and formed, with other mollusks, the food of the steamer or racehorse duck (*Micropteri brachypterus* and *Patachonicus*). The bottoms haunted by the Pectens have been found to be sands, sandy mud, and mud.

---

* Sir Anthony remarks that it is questionable whether any animal possesses [illegible]

Utility to Man.—As an article of food the genus is generally useful. On our own southern coasts, where the sea is prodigal of its contributions to the table, Pectens are considered a delicacy, and when well treated by a good cook make a rich and sapid dish, as might be expected from the name of them when so prepared, 'Quins.' The St. James's Cockle Shell, *Pecten Jacobæus*, was formerly the badge of the pilgrim who had been to the Holy Land.

Linnæus separated this extensive genus, that is, the Pectens properly so called, into three sections:—1. The auriculated equilateral Pectens. 2. The Pectens with one auricle ciliato spinous within. 3. (Including Lima) Pectens with their valves more gibbous on one side than on the other. Of the first of these, *Pecten Jacobæus* and *Pecten Pleuronectes* are examples; of the second, *Pecten Pallium*, the well known Ducal Mantle of collectors; and of the third, *Pectines flavicans* and *fasciata*, Linn.

Lamarck divided the genus into two sections only:—the first containing the species with the auricles equal or nearly equal; the second consisting of those which have the auricles unequal. The species cited as examples of the first and second divisions of Linnæus will serve as illustrations of this arrangement.

M. de Blainville separates the Pectens into four subdivisions:—1. (*Les Pelerines*) those species which are very inequivalve; the left valve being very flat (*Pecten Jacobæus*, &c.). 2. (*Les Soles*) Equivalve species which do not gape (*Pecten Pleuronectes*). 3. Species whose two valves are nearly equally concave, but the right rather the least, and having its inferior auricle less wide than that of the left, so as to produce a sort of notch, for the passage of the byssus, as he thinks (*Pectines gibbus* and *glaber*). 4. Species with striæ parallel to their border (*P. orbicularis*, fossil).

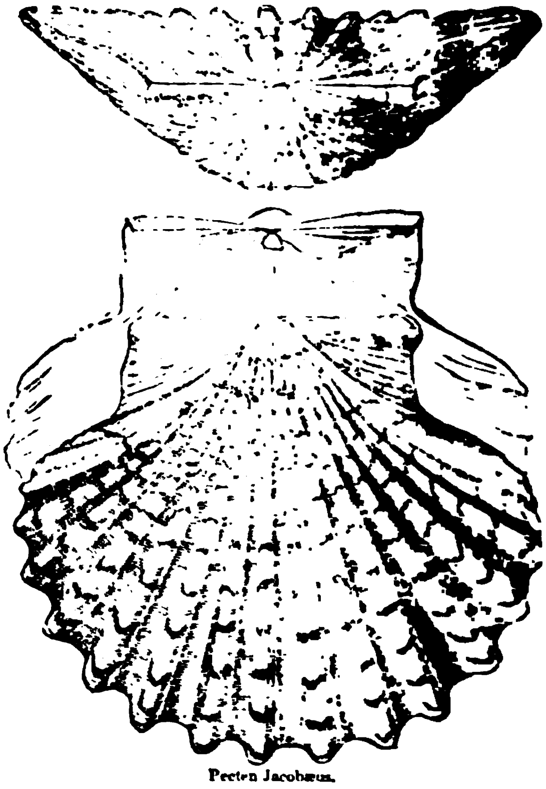
Mr. G. B. Sowerby makes the divisions five:—1. Both valves convex, equal or nearly in size (*Pecten turgidus*). 2. One valve flat, the other deep or convex (*P. Jacobæus*). 3. Both valves rather convex, not meeting all round (*P. Pleuronectes*). 4. Both valves convex, but unequal in size (*Pectines bifrons* and *aurantiacus*). 5. Irregular, apparently adherent by the outside, but only taking the form of whatever it is attached to in consequence of being close pressed to it (*Pecten Pusio*, Hinnites).

The same author states his belief that all the Pectens are attached by a byssus, although it is seldom observed, even in the living specimens. He accounts for this circumstance however by supposing that their attachment by the byssus is very slight, and he relates that he has seen them attaching their threads by means of their small and slender foot. Many of the Pectens, he adds, have a row of small sharp teeth on that side of the shell under the ear which forms a part of the sinus for the byssus. He had in a previous number of his *Genera* stated his certainty that *Lima* is attached by a byssus, but, as far as he could ascertain, *Pecten* is not. (See *Lima*, post.)

The following examples will illustrate the genus:—

Pecten Jacobæus.—Shell inequivalve, rather flattened above, with from fourteen to sixteen angulated rays; those of the lower valve longitudinally sulcated. Often agreeably variegated.

Locality.—The seas of Europe. (Fossil in Italy.)

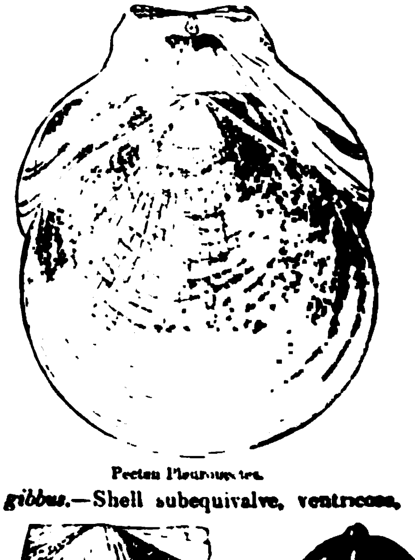


Pecten Jacobæus.

Pecten Pleuronectes.—Shell subequivalve, rather thin, smooth externally, somewhat convex on both sides.

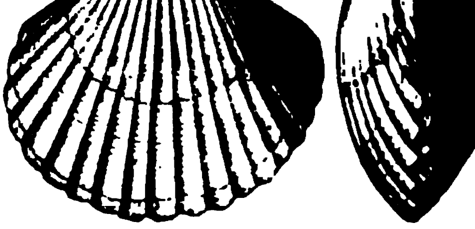
This species has the upper valve always coloured, generally reddish or rich reddish brown, and the lower one white, whence its name. In the inside of the valves are projecting, radiated, somewhat distant ribs.

Locality.—East Indian Seas. (Fossil in France, at St. Paul Trois Châteaux, department of Drome.)



Pecten Pleuronectes.

Pecten gibbus.—Shell subequivalve, ventricose, turgid.



Pecten Gibbus.

---

* Mr Gray's *Pecten vitreus*, which has the priority, was published in the Appendix to Captain Parry's 'Voyage' (1824), among the animals which were found within the Arctic Circle. It is smooth, and different from Captain King's *P. vitreus*.

rib, with from 20 to 22 radiating rays, which are somewhat ragged at their sides and interstices.

Locality.—The Atlantic and American oceans.

Pecten orbicularis.—Shell suborbicular, depressed, rather convex, with transverse concentric striæ on one valve, the other valve smooth; no rays. (Fossil: England—Wiltshire, Devizes; Sussex, chalk formation; France—[illegible], near Mans. Approaching *Pecten [illegible]*.)

Pecten [illegible].

The recent species are many, and the fossil species are probably more than the recent.

Fossil Pectens.

M. Deshayes, in his Tables, gives the number of living species as 51, and that of the fossil (tertiary) as 89; of which *Pectines Jacobæus, Laurentii, Pleuronectes, opercularis, [illegible], varius, ornatus, [illegible], [illegible], [illegible], Pusio* and *[illegible]*, are recorded by him as species found both living and fossil (tertiary). The form is found fossil in most of the strata from the crag to the oolitic series inclusive.

The number of recent species, including that which belongs to the genus *Hinnites* given in Deshayes's edition of Lamarck, is only 51, and that of the species fossil only is [illegible]. These numbers appear to be below the mark, allowing for varieties recorded as species (such as *P. Pusio*, Lam., which that zoologist considers to be only an impoverished variety of *P. varius*), for some recent species (*P. vitreus*, Gray, *P. [illegible]*, King, and *P. [illegible]*, Desh., and eight species recorded by Mr. G. B. Sowerby from Mr. Cuming's collection in *Zool. Proc.*, 1835, for example) are not inserted. Then of fossil species we find, for instance, no mention of *Pecten [illegible]* or *P. Lyelli* (Lea), nor of *P. [illegible]*, *P. Milleri*, and *P. Murchisonianus*, noted in Dr. Fitton's *Systematic and Stratigraphical List of Fossils* (below the chalk), and figured in his excellent memoir.* For fossil species, the reader is further referred to *Min. Conch.*; Mantell's *Tabular Arrangement of the Organic Remains of the County of Sussex* ('Geol. Trans.,' vol. iii., 2nd series); Phillips's *Illustrations of the Geology of Yorkshire*; and Lonsdale's memoir *On the Oolitic District of Bath* ('Geol. Trans.,' vol. iii., 2nd series); Lea's *Contributions to Geology*; Von Buch's *Pétrifications Recueillies en Amérique* (fol., Berlin, 1839); and the works of Knorr and Goldfuss.

HINNITES. (Defrance.)

Mr. G. B. Sowerby, in his paper on *Hinnites*, in the 'Zoological Journal' (vol. iv.), says, 'The examination of a number of specimens of three or four decidedly congenerous species have conducted me to the results which will be explained in the following observations.—First I must inform naturalists that one of our commonest British shells, to which neither M. Defrance nor Mr. Gray has referred, belongs to this genus, namely, *Pecten Pusio* of some, *P. distortus* of others. The singular manner in which this shell almost constantly becomes pressed in and takes the shape of the substances to which it adheres, and the extremely rare occurrence of an opportunity of observing its byssus, may have given rise to the idea of its being adherent by its outer surface to those substances, whereas the contrary is really the case, as is proved by the very young specimens which never have any appearance of adherent outer surface. The [illegible] in the shell called *Hinnites* by M. Defrance (Mr. Gray's [illegible] of it) has undoubtedly been the cause of leading him to describe them as adherent by their valve [illegible] and not by a byssus,' &c. Mr. Sowerby then proposes an amended generic character for *Hinnites*, [illegible] in which he describes the shell [illegible], and gives a list of five species, *Hinnites Pusio* (*Pecten Pusio*, *P. distortus* of some) being the last. The same author, in his *Genera*, speaking of *H. Pusio*, says, 'Irregular, apparently adherent by the outside, but only taking the form of whatever it is attached to in consequence of being close pressed to it. This has generally been thought to belong to the *Spondylidæ*, and has been named *Hinnites* by Defrance. We have however proved it to be a *Pecten*. See *Zool. Journ.*'

M. Rang notices *Hinnites* as fossil only.

M. Deshayes, in his last edition of Lamarck, thus defines the genus:—

Animal unknown.

Shell oval, irregular, adhering by the right valve, inequivalve, subequilateral, perfectly closed; its upper part terminated on each side by auricles similar to those of Pectens; cardinal border straight, toothless, prolonged with age into a small heel (talon); ligament thick, contained in a narrow and very deep gutter (gouttière).

M. Deshayes then proceeds to observe that the genus *Hinnites* forms one of the intermediate links serving to connect the *Pectens* to the *Spondyli* and *Oysters*, but that it has more analogy with the last than with any others of the same family. The shells forming the genus are, he says, irregular, inequivalve, and adherent by the right valve, which is generally larger and deeper than the other. Its summit (crochet) is sufficiently regular, which indicates that in its youth the shell has more regularity. The greater part of the lower surface is very irregular, and exhibits a large adhering surface. The upper valve is flattened, more regular, and presents striæ or longitudinal furrows, which are more or less numerous and scaly according to the species. The hinge is nearly similar to that of the Pectens; it is accompanied on each side by short ears, which are nearly equal and very close, *so as to leave no passage for a byssus*. The cardinal border is straight, thicker than in the Pectens; the gutter of the ligament is much narrower, much deeper, and more prolonged superiorly, which gives it some resemblance to that of *Pedum*; in age the cardinal border offers a plane oblique surface, comparable to that of *Pedum* and *Spondylus*, and which is not remarked in the *Pectens*. The muscular impression is very large and rounded, and the pallial impression, as in *Spondylus*, is very much approximated to it. A small number of species only belonging to the genus is as yet known, and a single living species (*Hinnites sinuosus*, Desh.; *Pecten sinuosus*, Lam.; *P. Pusio*, Pennant, Sow.; *Ostrea sinuosa*, Gmel., Maton, and Rackett) has been recorded.

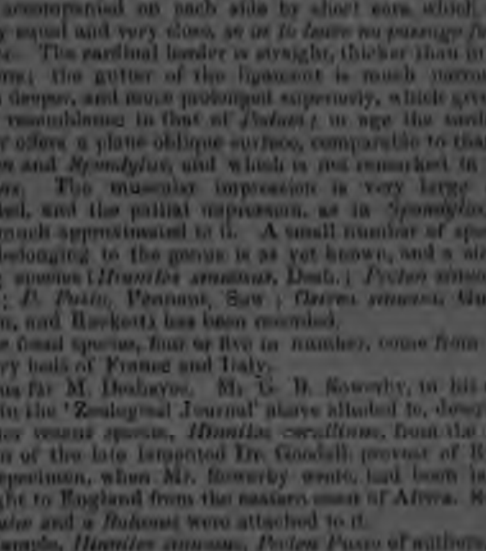
The fossil species, four or five in number, come from the tertiary beds of France and Italy.

Thus far M. Deshayes. Mr. G. B. Sowerby, in his memoir in the 'Zoological Journal' above alluded to, describes another recent species, *Hinnites corallinus*, from the collection of the late lamented Dr. Goodall, provost of Eton. The specimen, when Mr. Sowerby wrote, had been lately brought to England from the eastern coast of Africa. Some *Serpulæ* and a *Balanus* were attached to it.

Example, *Hinnites sinuosus*, *Pecten Pusio* of authors.

Description.—*Shell* ovate, unequally sinuous, variegated with brownish orange and white, and marked with numerous very narrow, striæform, and scaleous rays.

Locality.—The British Ocean and British Channel.



Hinnites sinuosus:
a, outside of under valve.

Lima. (Brug.)

Generic Character.—Animal oval, having the lobes of the mantle separated nearly throughout their extent, larger than the valves of the shell, and turned towards the [illegible] as a [illegible]; this part of the border is wide, and furnished throughout its extent with numerous tentacular, elongated, and annulated cirrhi. *Branchiæ* rather large, equal, and separated (écartées); foot cylindrical, vermiform, rather club-shaped, and terminating in a small sucker (ventouse), by means of which the animal can fix itself to submarine bodies; *no byssus;* buccal aperture oval, furnished with large foliaceous lips, terminated on each side by triangular and obliquely truncated labial palps. (Deshayes.)

---

* 'Observations on some of the strata between the Chalk and Oxford Oolite in the south-east of England,' by William Henry Fitton, M.D., F.R.S., &c. ('Geol. Trans.,' vol. iv., 2nd series.)

Shell longitudinal, subequivalve, auriculated, rather gaping on one side of the valves; umbones distant (écartées), their internal facets inclined inwards. Hinge toothless. Cardinal pit partly external, receiving the ligament.

Among the observations of Lamarck on this genus, we find him remarking that here the peculiar notch on the lower valve is no longer to be found; a simple separation (écartement) between the valves gives place to a sufficient lateral opening, and the pit which receives the ligament is become wider and more internal. Thus the *Limæ* have necessarily a great relationship to the *Pectens*, whence many authors have confounded them in the same genus. Linnæus, considering only the want of cardinal teeth in these shells, arranged them among his oysters; but their free regular and nearly equivalve shell requires their separation from the oysters, as the separated umbones and the cardinal pit of the *Limæ* make it necessary to distinguish them, as Bruguière did, from the Pectens.

Lamarck concludes by noticing their colour, which is nearly always white, and by observing that the animal seems to be furnished with a foot fitted for spinning a byssus.

M. Deshayes, in the last edition of Lamarck, states his opinion that *Lima* is a genus which well deserved to be separated from its congeners in the family of *Pectinidæ*. Not only, says M. Deshayes, has it no byssus, but its mantle, like the shell, gapes much, and the large re entering edge of the former is furnished with a great number of vermiform flexible tentacula, which seem formed, like the antennæ of insects, of gradually decreasing articulations. Between these tentacles there are no tubercles with smooth surfaces similar to those of the *Pectens*, the *Spondyli*, and the *Pedu*. The foot has a particular form, recalling to the observer that of *Lucina* or *Loripes;* it is elongated, narrow, cylindrical, and rather thickened at its free extremity, where it terminates in a sort of sucker, which, according to the observations of M. Quoy, serves to fix the animal upon solid bodies even of the most smooth surface. The mouth is placed between two lips comparable to those of *Pinna;* they are foliaceous, descend upon the lateral parts of the body, and terminate on each side in a pair of labial palps, which are truncated and triangular. The branchiæ are rather large and equal. Those on one side are separated from those on the other by a rather wide space, in which may be easily perceived the adductor muscle, on the posterior face of which the anus terminates. This muscle seems more extensible than in the greater part of the mollusks of the same class. When it is not contracted, the valves are widely opened, and the animal has the power of impressing on it frequent and sudden contractions, the rapidity of which is facilitated by the extreme elasticity of the ligament of the valves. By means of these reiterated contractions the animal can flutter in the water, to use the happy expression of M. Quoy, and one must run after it to catch it among the corals or in the shallows where it dwells. M. Deshayes concludes that from this remarkable union of characters it might be possible for zoologists to decide upon forming of this genus a small family distinct from the Pectens, but placed in their neighbourhood.

The power of fluttering through the water is possessed by some of the Pectens, perhaps all. [CONCHIFERA, vol. vii., p. 433.] With regard to the absence of byssus, Dr. Turton, some years ago (1826), in his description of *Lima tenera*, remarked that he had dredged up half a dozen living specimens of various sizes in the British Channel, and stated that they had no byssus attached to them, nor had *Lima Loscombi* when taken alive.

Geographical Distribution.—This form is widely distributed, and is generally found in the seas of warm and temperate climates, where it has been taken at depths ranging from the surface to thirty fathoms.

Mr. Garner remarks that in the heart of *Lima* there are two ventricles, the rectum passing between them.

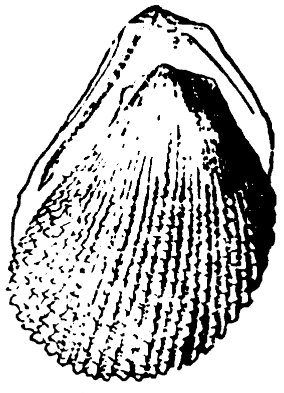
The recent species are not numerous. M. Deshayes, in his Tables, gives the number as 8. In his last edition of Lamarck, the number of recent species is only 6, but this seems to be below the mark; for instance, neither *Lima tenera* (Turton) nor *Lima Loscombi* is there noticed. *Lima tenera* (Chemn.) is quoted as a variety of *L. glacialis.*

Example, *Lima squamosa.*

Shell oval, depressed, clipped as it were anteriorly, white; ribs squamous, rough as a file; hinge oblique, margin crenated.

Locality.—Seas of America.

There is a variety which has the scales less numerous.



Lima squamosa.

Fossil Limæ.

The number of fossil species noted in the tables of M. Deshayes are 13 (tertiary), and the following species are recorded as living and tertiary, *Limæ inflata, squamosa, lingulata,* and *nivea*. In the last edition of Lamarck the number is 18. This seems to be too small. Neither *Lima semisulcata* nor *L. subovalis*, for instance, figured in Dr. F[illegible] memoir above alluded to, from Blackdown, appears among the species.

We are not aware of any *Limæ* found below the lias, though the form occurs in it (ex. *L. antiquata**) and in the inferior oolite; nor do we know of any recorded from the London clay, though some occur in the calcaire grossier and in the corresponding Italian beds.

Pedum. (Lam.)

Generic Character.—Animal oval, oblong, flattened, having the lobes of the mantle open throughout their circumference, thickened on their edges, and furnished on [illegible] part with many rows of tentacular cirrhi, and, at regular distances, tubercles with smooth surfaces. A pair of [illegible] branchiæ descending on each side to the edge of the lower border of the mantle; abdominal mass small, having anteriorly and high up a small vermiform foot, and at its base a silky *byssus* of some size; mouth oval, having on each side a pair of labial triangular palps. (Deshayes.)

Shell inequivalve, subauriculate, lower valve gaping; umbones unequal and distant. *Hinge* toothless; ligament partly external, inserted in an elongated canaliform pit which is hollowed out in the internal wall of the umbones. Lower valve notched near its posterior base. (Lam.)

The animal is described and figured by MM. Quoy and Gaimard, in the 'Zoology' of the *Voyage of the Astrolabe*, and has, as M. Deshayes observes, much analogy to that of the *Pectens* and *Spondyli*. According to MM. Quoy and Gaimard, the form is assimilated to that of the shell. The lobes of the mantle are separated throughout their circumference, except in the width of the upper border, which is very short; the edges are thickened and furnished with a great number of fine unequal tentacles, between which appear, at equal distances, small smooth tubercles, similar to those described by Poli and others in the *Pectens* and *Spondyli*. The branchiæ are large, nearly equal, and descend between the lower borders of the mantle; those of the one side are separated from those of the other by a flattened space, which is rather wide, and forms the anterior and lower part of the body of the animal. At the lower part of this space is seen a small vermiform foot, at the base of which is a rather large yellowish byssus, which is silky and has a nacreous appearance. Behind the foot is the mouth, which is oval, and furnished on each side with a pair of triangular short palps, fixed by one of the sides of the triangle and free otherwise; they are striated like the branchiæ which they touch. The mantle on the right side presents at its superior and anterior part a notch in conformity with that of the shell for the passage of the byssus. The single adductor muscle is placed towards the upper and posterior part of the animal, the anus passes behind it, and terminates at the summit of a small appendage floating between the branchiæ.

---

* Not mentioned in the last edition of Lamarck.

The only example known is *Pedum Spondyloideum*.

Description.—*Shell* ovato-cuneiform, pinnulate; whitish tinged with red or purplish, especially near the umbones; the upper valve flat and striated longitudinally; the lower valve largest, with the lateral edges turned up and raised above those of the upper valve.

There is a smaller variety, much more round, and generally more delicate.

Locality.—East Indian Seas (Isle of *France*, &c.). MM. Quoy and Gaimard found the species at the island of Vanikoro, where it was abundant, living partially encased in Madrepores, especially *Astreæ*. M. Quoy is of opinion that it is capable of hollowing out the holes in which it is found for itself; and he found young and old individuals burrowed in the same mass of Madrepore proportionally to their size. M. Deshayes suggests whether the animal having first attached itself to the coral, the growth of the latter may not partially envelop the shell.

Shell of Pedum Spondyloideum.

Plicatula, *Spondylus*, &c. will be treated of under the title SPONDYLIDÆ. We now shall draw the attention of the reader to those more rough forms, most of which Linnæus included in his fourth section.

OYSTERS.

Gryphæa (Lam.), fossil principally.
Exogyra (Say), fossil only.

These two genera are so established in fossil catalogues, that it may be convenient to retain their names; but we agree with Mr. G. B. Sowerby and M. Deshayes, that, physiologically considered, they ought to be abandoned. Mr. Sowerby, in his 'Genera,' remarks that the particular points upon which Lamarck depends for his distinction between the Oysters and *Gryphææ* are, 1st, the apparent regularity of the latter; 2nd, their being scarcely if at all attached; and 3rd, the generally large, involute, spiral umbo of the lower valve. To the first Mr. Sowerby answers, that though the *Gryphææ* are in general apparently more regular than the *Ostreæ*, they cannot be considered as regular shells, and that they are moreover very variable; secondly, the *Gryphææ*, as well as all other *Ostreæ*, are attached by the umbo of the larger and convex valve, and this particularly in the young state (in which state in fact it is impossible to distinguish between one and the other); moreover both become free as they advance in size; and if the *Gryphææ* are thus apparently more regular, it is because in their young state they have lived in situations where they could only become attached to small regular objects, while the *Ostreæ*, having lived in more rugged and irregular situations, and consequently remaining attached for a longer time, have partaken more of the regularity of their native situation. 'Indeed,' adds Mr. Sowerby, 'there is sufficient evidence that an oyster, when by any chance it becomes attached to a small smooth object, where it is comparatively free, becomes also regular in the same degree: thirdly, we cannot approve of the term *spiral* as at any time applicable to the umbo of the lower valve of the *Gryphææ*; when young, it is not *involute*; and though Lamarck mentions the size of this as one important distinguishing mark of his genus, he gives the characters of several species in which this part is *small*. Another circumstance in which the *Gryphæa* is thought to differ from *Ostrea* has been dwelt upon by some, an obscure lobe or sulcus observable on the right side, particularly of the lower valve; but this is far from being distinct in some species.'

M. Deshayes observes, in the last edition of Lamarck, that if we study the oysters with attention, the first thing that strikes us is that the species are very variable in form. If a large assemblage be collected, some individuals of these variable species will be almost always found whose umbo is fashioned according to the manner in which the shell is attached, so as to be turned either laterally or upwards, as in *Gryphæa*. Thus it may be said that the greater part of the species of oysters have their gryphoid varieties. If a rigorous application of the characters of *Gryphæa* be made to these varieties, they may be comprehended in that genus, whilst the others may remain among the oysters. Between the *Gryphææ* and the oysters the passage is insensible, and in a large series of species and varieties it would be impossible rationally to draw the line between the two genera. Indeed, the difficulty of drawing this line is increased when we perceive all the forms of both genera in the same species. M. Deshayes goes on to notice the observation of Lamarck, that in the *Gryphææ* the shell is free: this, says M. Deshayes, is an error; there are *Gryphææ* which affixed themselves to solid bodies, like the oysters, and there remained during the whole of their existence; all the others were fixed for a longer or shorter period in their youth only, and only became free as they advanced in age. This observation will apply equally to many species of oysters, and particularly those which live on muddy or sandy bottoms. In the oysters, as well as in the *Gryphææ*, the valves are unequal, and in both genera the left valve is always largest. The involute spiral curvature of the umbo of *Gryphæa* is perhaps the strongest point of distinction, and it certainly is constant in many species; but in all it is not. In this respect the variations are comparable to those in the oysters: if the involution exists in the *Gryphoid oysters*, it exists also in the Ostreiform *Gryphææ*. The hinge and muscular impression in both *Ostrea* and *Gryphæa* are so similar, that M. Deshayes expresses his surprise that Lamarck could be induced to establish so useless a genus.

But if the generic claims of *Gryphæa* be untenable, those of *Exogyra*, established by Say for the reception of the *Gryphææ*, whose umbo, instead of rising above the valves, take a lateral direction, have still less foundation. There is not, says M. Deshayes in conclusion, a single character which is not to be found in the oysters, and sometimes in the varieties of the same species. (See further, *Ostrea*, post.)

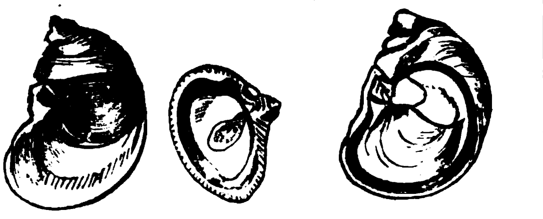
Geological Position.—Gryphææ are found in almost all the strata down to the lias (inclusive).

The so-called species are numerous. Thirty-four are enumerated by M. Deshayes in his last edition of Lamarck, and of these only one, *Gryphæa angulata*, is recent. In the Tables of M. Deshayes, the number of living species consists of this unit, and of fossil (tertiary) three species.

Gryphæa incurva (Lam.)

are there recorded. The reader may consult the catalogues above noticed for fossil species and localities.

Exogyra is included in the species of *Gryphææ* noticed in the last edition of Lamarck. Von Buch has recently published a fine species under the name of *Exog. polygona*, from Montan (South America), where it was found in company with Pectens by M. Alexandre de Humboldt.



Exogyra conica (Upper Green-Sand, Gault, Lower Green-Sand, Blackdown).

Ostrea. (Linn.)

Generic Character.—Animal oval, oblong, flattened, often irregular; lobes of the mantle thick and fringed on the borders, separated throughout their extent; no foot; mouth moderately furnished with two pair of elongated lanceolate palps; branchiæ large, curved, nearly equal. The non-symmetrical heart not having its basis upon the intestine, which last terminates behind the adductor muscle by an anus which floats between the lobes of the mantle. (Deshayes.)

Shell adherent, inequivalve, irregular; umbones distant, and becoming very irregular as the animal advances in age; upper valve smallest, gradually displacing itself, and advancing forwards as the animal grows older. *Hinge* toothless; ligament demi-internal, inserted in the cardinal pit of the valves; the pit of the lower valve increasing with the age of the animal, as well as the umbo, and acquiring sometimes a great length.

Geographical Distribution.—Very wide, and principally in the seas of temperate and warm climates: no species appear to have been met with in the Polar expeditions very far north. Oysters have been taken on gravel and sand, in æstuaries, and on the sea-coast, sometimes attached to rocks, trees,[*] &c., at depths varying from the surface to 17 fathoms. In the British Museum there is a good sized crab, on the back and claws of which are many oysters. [Crab, vol. viii., p. 126.]

It is impossible not to hold in the greatest respect the opinions of so distinguished a geologist and naturalist as Von Buch, and when we find him up to the present time (for in his *Pétrifications Recueillies en Amérique*, folio, 1839, above alluded to, he still insists on the distinction) separating the *Exogyræ* from the *Gryphææ* and the *Oysters*, it becomes necessary that reasons to which his name must give deserved weight should be critically examined. In the 'Annales des Sciences Naturelles' (May, 1835), Von Buch says, 'Les Huitres ont une tendance à s'isoler sur un plan droit, les Gryphées sont profondes, et les Exogyres ont une tendance marquée à former une carène.' This, observes M. Deshayes, is true as a general proposition; but it wants exactness when one comes to examine in detail a great number of individuals of the species. If the oysters in general have a tendency to extend themselves, nearly all take different shapes according to the form and extent of the body on which they fix themselves; and indeed M. Deshayes, in his work on the fossil shells of the environs of Paris, has made it appear that in a single species is found nearly all the forms belonging to the oysters properly so called, to the *Gryphææ*, and to the *Exogyræ*. 'If,' observes M. Deshayes, 'we take the best characterised species in the group of *Gryphææ*, we find them variable, and if we compare the young individuals with the young of oysters, we find no difference. Take as the point of departure *Gryphæa arcuata*, a species the umbo of whose lower valve is the most elevated, and we shall find an insensible passage to the oysters properly so called, established by many species in which this part, becoming less and less projecting, finishes at last by disappearing in this form to take that of the oysters; this transition is so insensible, that we regard the rational limit of the two genera as impossible. M. de Buch states that the *Gryphææ* have a lateral lobe, but this lobe is no more constant than the other characters, and is of no more value than they are. There are species in which it is scarcely marked, others in which it is deeper, but in some individuals it is altogether wanting. This lobe, regarded as characteristic by M. de Buch, is also found, as he acknowledges, in the oysters, and so is common to the two genera which he would separate; it also shows itself in some *Exogyræ*: the small degree of constancy which it offers renders it unimportant and valueless. The *Exogyræ*, says M. de Buch, also have a tendency to take a dorsal angle. We shall first observe that the type of the genus *Exogyra costata*, Say, has never any keel; and next, that it is absent in many other species. If some *Exogyræ* have a dorsal keel, others have it not; the character then cannot be regarded as constant; this therefore is insufficient to found the new genus. Nothing then remains as a character but the form of the umbo. In *Exogyra* it is rolled on itself laterally; in *Gryphæa* it is elevated upwards. In this respect the examination of the *Exogyræ* becomes interesting. Many species of oysters have the umbo always turned to the side; others, which have it ordinarily straight, have accidentally this part equally turned laterally; the *Exogyræ* bear such resemblance to the oysters, that it is impossible to trace the limits of those two groups. But this is not all; if the *Gryphææ* pass to the oysters by the progressive lowering of the umbo, they pass also to the *Exogyræ* by a certain number of species with the umbo more and more oblique, so that the distinction between the *Gryphææ* and *Exogyræ* is not more clear than that between the oysters and *Gryphææ* on the one side, and between the oysters and *Exogyræ* on the other. Thus the *Gryphææ* and the *Exogyræ* are not two diverging branches of the oysters, but these genera form a circle in which we pass from the oysters to the *Gryphææ*, from the *Gryphææ* to the *Exogyræ*, and from the *Exogyræ* to the oysters and all by insensible gradations. The intimate relations which connect these three genera, the concatenation of their characters, the manner in which, so to speak, they penetrate each other mutually, afford, in my opinion, the most convincing proof that these three genera, artificial when separated, form, when reunited, one very natural genus; nor can we agree with M. de Buch, that they are separate in a manner '*nette, précise, et tranchée.*'

'M. de Buch considers the lobe of certain *Gryphææ* and the enlargement observable in some oysters (*Ostrea carinata*) as analogous parts to the auricles of the Pectens. I am far from partaking of the opinion of the learned geologist. I perceive too great a difference between the animals of the Pectens and of the oysters in the more important parts of their organization to admit in one the parts of the other in a certain state of modification. The part of the mantle which in the Pectens produces the auricles, is not that which forms the lobe in the *Gryphææ*. All the Pectens, without exception, are regular and have auricles; all the oysters, without exception, are irregular and want auricles like those of the Pectens. In the oyster cited by M. de Buch (*Ostrea carinata*, and other analogous species) the enlargement of the upper part is due to the position of the muscle upon this enlargement, and to the adherence of the shell on this enlarged part. It cannot therefore be compared to the auricles of the Pectens, for they have no reference to the adductor muscle. When we know the differences between the animals of the Pectens and oysters, we cannot admit the conclusion of M. de Buch, namely, that the oysters are Pectens without auricles or having them horizontal, whilst the *Gryphææ* have only one represented by the lateral lobe, the other being abortive as a consequence of the form of the shells.'

Without pursuing the argument of M. Deshayes further, we must conclude this discussion, which is of high interest to those who seek for the principles on which generic distinctions should be founded, as we began it. *Gryphæa* and *Exogyra* may be introduced to facilitate references, and are convenient but arbitrary subsections: that they have any claims to separation from the oysters, as distinct types, we cannot admit.

The True Oysters have been divided into two groups which may be satisfactorily used by zoologists and geologists as subdivisions of this numerous genus.

A. True Oysters with simple or undulated, but not plaited valves.

This considerable group, which consists of between thirty and forty recorded species (recent), may be illustrated by well known *Ostrea edulis*, or *Common edible oyster* of the European seas.

---

[*] Mangrove oyster, prized in the West Indies for its delicious flavour: often found in company with *Perna Ephippium*, which is considered even a greater delicacy than the former.

These delicious oysters are the *Ostrea* of the ancient Italians; *Ostriche* of the modern Italians; *Ostras* of the Spaniards; *Austern* of the Germans; and *Huîtres* of the French.

The ancient Roman epicure well knew the value of the British oysters (Juvenal, iv. 140), nor have they lost their celebrity in modern times.

But excellent as the oysters of Britain undoubtedly are, there are many degrees of that excellence, the animal varying much both in size and flavour, according to the nature of the coast and the food with which the locality is furnished. The oysters on the south coast are generally very well flavoured; but it has been said that the best are found at Purfleet and the worst at Liverpool. The Tenby oyster is large and rather coarse; but when fat is well-flavoured, and excellent when well stewed or pickled. Colchester and other places in Essex are the great nurseries or feeding-grounds for supplying the metropolis, and indeed, in a great measure, England generally, with this highly-flavoured species. Here the oysters collected at various places on the coast, even as far as Scotland, are brought and laid on beds in creeks along the shore, where their flavour and size are rapidly improved. They have been known to augment the circumference of their shells even to the extent of an inch during the first two months, but in such cases the concavity within the valves is shallow. Bishop Sprat, in his 'History of the Royal Society,' gives a detailed account of the treatment of oysters in the beds or layers.

The favourite food of the oyster, according to M. Gaillon, consists of a green *Navicula* (*Vibrio ostrearius* of authors) and various species of that and other genera of *Infusoria*: these make the oyster fat, tender, and peculiarly well flavoured; others again are said to be injurious to it.

The number of vessels employed in dredging for oysters is supposed to be about 200, giving employment to some 400 or 500 men and boys; and the quantity of oysters bred and taken in Essex, mostly for London consumption, has been stated at 14,000 or 15,000 bushels annually.

Property necessarily exposed, as these valuable oyster-beds must be, required the protection of the legislature. (Stat. 31 George III., c. 51; 48 George III., c. 144; and 7 & 8 George IV., c. 29.) By the last-named statute, (which repeals 31 George III., c. 51,) sec. 36, stealing of oysters or oyster-brood from any oyster-bed, laying, or fishery, is larceny, and the offender upon conviction shall be punished accordingly. Moreover, if any person shall unlawfully and wilfully use any dredge, net, &c., for the purpose of taking oysters or oyster-brood, within the limits of any oyster-bed or fishery, every such person shall be deemed guilty of a misdemeanor, and, upon being convicted thereof, shall be punished by fine or imprisonment, or both, such fine not to exceed 20*l.*, and such imprisonment not to exceed three calendar months. The statute contains a proviso that the catching floating fish with any net, instrument, or engine adapted for catching such fish, within the limits of any oyster-fishery, shall not bring the fisher within the penalties of the Act.

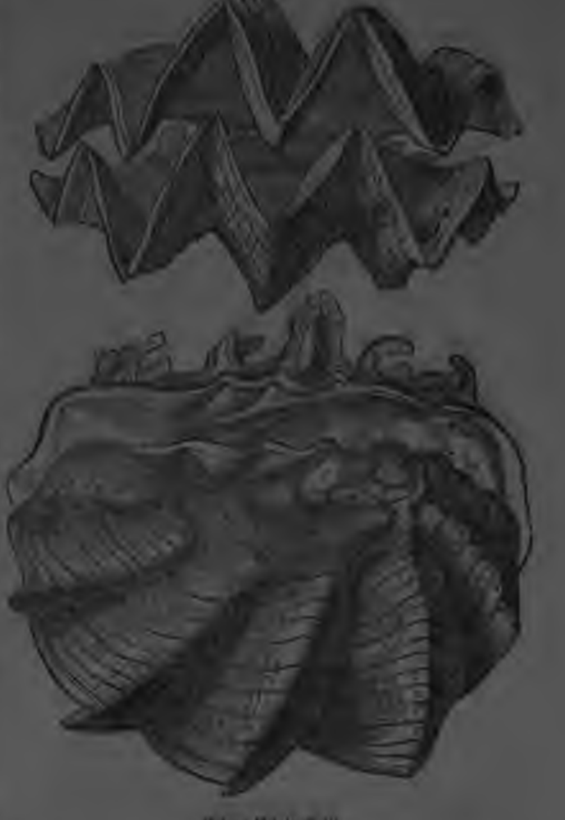
The bill for the protection of the oyster-fisheries in Scotland, now (April, 1840) before parliament, provides that any person in Scotland knowingly stealing oysters from a bed, laying, or fishery, which is sufficiently marked as the property of other persons, shall be deemed guilty of theft, and punished accordingly; and that any person using any net, dredge, or other instrument, within the limits of such oyster-fishery, for the purpose of taking oysters, although none be actually taken, shall be deemed guilty of an attempt to commit theft, and be liable to fine or imprisonment, the fine not to exceed 20*l.*, and the imprisonment not three months, with a clause that nothing in the act shall prevent persons from catching floating fish in an oyster-fishery with instruments adapted for taking floating fish only.

B. True Oysters, with the borders of their valves distinctly plaited.

Of this group, consisting of more than thirty recorded species (recent), *Ostrea Crista Galli*, the *Cockscomb Oyster*, will serve as an example.

Description.—Shell varying in form according to the bodies to which it adheres, but generally somewhat rounded, very much plaited, the plaits longitudinal and angulated; internal border rough; externally violet, purplish, or reddish-white. The shell externally has subgranulous striæ, and rarely elevated subtubular scales.

Locality.—East Indian Seas.



Ostrea Crista Galli.

The number of species of *Ostrea*, excluding *Gryphæa*, given by M. Deshayes in his Tables, is 54 living and 72 fossil (tertiary). The species there recorded as both living and fossil are *Ostrea Cornucopiæ*, *edulis*, *Virginica*, *Hippopus*, *navicularis*, *Forskalii*, and a 'new species.'

In the last edition of Lamarck the number of recent species, some of which may be varieties, is 55, and the number of fossil only 52.

The fossil species occur as low down as the lias (inclusive), and some of the species are considered characteristic of certain strata, *Ostrea dilatata*, for instance, of the Kimmeridge clay, or oak-tree clay of Smith, and *O. pulchra* of the plastic clay.

Placuna. (Brug.)

Animal very much compressed.

Shell free, irregular, very much flattened; valves delicate and almost translucid, quite translucid in some species, nearly equal, and subequilateral; hinge internal, offering on one valve two longitudinal, trenchant, rib-like elevations, converging at the summit, and, on the other, two furrows, corresponding to these ribs, and giving attachment to the ligament; muscular impression subcentral and rather small. (Rang.)

Geographical Distribution, &c.—The zone of warm climates: the species now known are from the East Indian and Red Seas, and have been taken on sandy bottoms.

M. Deshayes remarks that the animal is not known, but that he is convinced that it has a great analogy to that of *Anomia*.

The number of species recorded in the list of M. Deshayes is three living and one fossil (tertiary). Of the living species, *Placuna papyracea* is noted as both living and fossil (tertiary).* Four species are enumerated in the last edition of Lamarck as they were in the first; but the fourth, *Placuna pectinoides* (fossil), is considered to have all the characters of *Plicatula*, and is therefore removed by M. Deshayes to that genus. Mr. G. B. Sowerby had previously given a similar opinion. (*Genera.*) The species best known are, *Placuna Placenta*, vulgarly known as the *Chinese Window Oyster*, the valves of which are sufficiently delicate to transmit light; and *Placuna Sella*, known to collectors as the *Saddle-Oyster* (from Tranquebar, &c.).

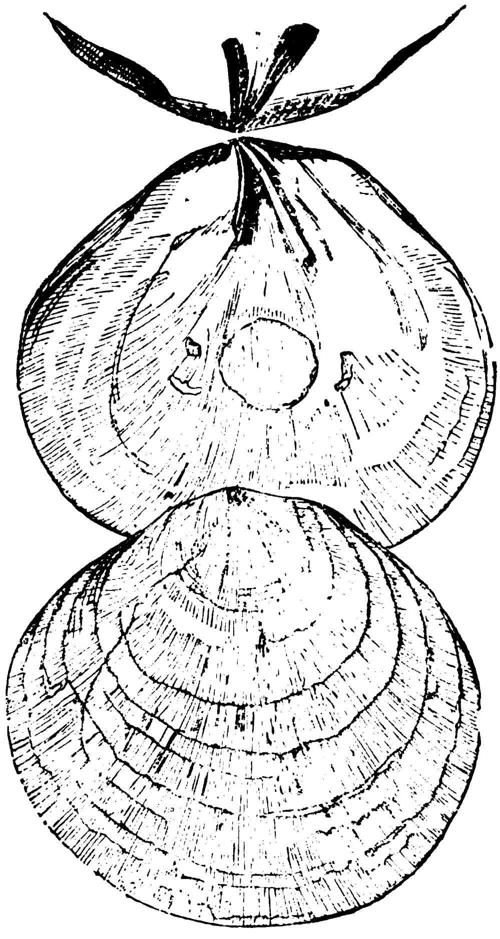
---

* The papyracea of Lamarck in [illegible]

Example, *Placuna Placenta.*

Description.—Shell suborbicular, flat, pellucid, white, with longitudinal, subdecussate striæ.

Locality.—East Indian Seas.



Placuna Placenta.

Placunanomia. (Brod.*)

Generic Character.—Animal probably intermediate between that of *Placuna* and *Anomia.*

Shell adherent, subequivalve, irregular, flattened, plaited towards the margin, vitreous internally. *Hinge* internal, with two elongated, thick, subcurved, divaricated teeth converging at the base in the lower valve, and two ligamentiferous furrows opposite in the upper valve. *Lower valve* superficially fissured externally towards the hinge, the subosseous organ of adhesion inserted between the laminæ of the shell and filling the fissure externally. Muscular impression in each valve subcentral. In the upper valve the impression of the organ of adhesion is superadded.

This interesting genus partakes of the characters of the genera *Ostrea*, *Plicatula*, *Placuna*, and *Anomia.* It may be regarded as the connecting link between the two latter. With an arrangement of the hinge approaching very nearly to that of *Placuna*, it has the distinguishing organization of *Anomia*, while the external appearance of the shell, especially if viewed *in situ*, bears the strongest resemblance to *Plicatula* or some of the plicated *Oysters.* The organ of adhesion, which in its bony character (for it is more bony than shelly) resembles that of *Anomia*, does not perforate the lower valve directly, but is inserted between the laminæ of the internal surface of the lower valve above the muscular impression and below the hinge, and passes out into an external, irregular, somewhat longitudinal superficial fissure or *cicatrix*, which is narrowest at the hinge margin, and which it entirely fills to a level with the surrounding surface of the shell. (Broderip, *Zool. Proc.*, February, 1832.)

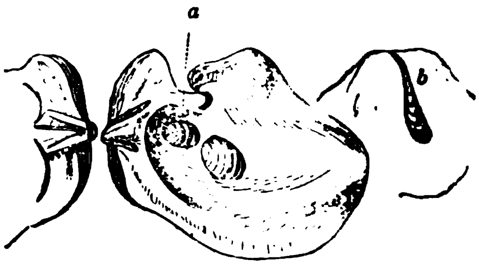
Geographical Distribution, &c.—The species are widely diffused, and inhabit the seas of warm climates in both hemispheres. Mr. Broderip has described four (*Zool. Proc.* and Müller's *Synopsis*) brought to this country by Mr. Cuming from the West Indies, Central America, and other western localities. They were dredged from sandy mud and muddy bottoms, adhering to bivalve shells, dead and living, and dead coral, at depths of six, eleven, and seventeen fathoms; of these, *Placuna echinata* wears something of the appearance of the short-spined *Spondyli.* Besides the species above alluded to, Mr. Broderip states that Mr. Sowerby furnished him with an odd valve of a large species from Luçonia, which was beautifully iridescent internally; but as it was believed that this was identical with the fine shell sold by him to the British Museum, Mr. Broderip left the description of it to the officers of that establishment. Mr. Sowerby had some other odd valves, which Mr. Broderip thought might prove new, and the latter possessed two or three specimens adhering to *Spondyli*, from an unknown locality; but they appeared to be young, and though he was inclined to think that there was a new species among them, he deemed it prudent to wait for further information.

M. Deshayes remarks that this genus establishes the passage between *Placuna* and *Anomia*, and that it shows that the V-shaped tooth of *Placuna* is only an extreme modification of the large callosity of the *Anomiæ;* he adds that a fossil shell found in Egypt, and which has been taken for a *Placuna*, is a new step, as regards the hinge, between the *Anomiæ* and *Placunæ.*

Example, *Placuna Cumingii*, Brod.

Description.—Shell subround, obscurely silvered, white, flattened; margin plaited, the plaits very large; length two inches and a half, breadth seven-tenths of an inch, height two and three-quarters inches.

Locality.—Shores of Central America (Gulf of Dulce, Province of Costa Rico); dredged from a muddy bottom, at the depth of eleven fathoms, attached to dead bivalve shells and dead coral.



Placunanomia Cumingii.

a, Internal appearance of the organ of adhesion; *b*, the same seen extern[illegible]

Anomia. (Brug.)

Generic Character.—Animal very much compressed, having the borders of the mantle delicate, and furnished externally with a row of tentacular filaments; foot rudimentary; adductor muscle divided into three branches, the largest of which passes by a notch in the lower valve in order to attach itself to an opercular stony or corneous piece fixed to marine bodies.

Shell adherent by its opercular piece, inequivalve, inequilateral, irregular, delicate, and often translucid; the flat valve most flattened, having a round or oblong notch near the umbo for the reception of the opercular piece; the other larger and more concave; both joined by a short and thin ligament; muscular impression separated into three portions. (Rang.)

Geographical Distribution.—The recorded species are generally quoted as coming from the European seas and the Atlantic Ocean. The depths at which they have been taken are stated to vary from the surface to twelve fathoms, adhering to oysters, and other shells, rocks, &c.

The species are not very numerous; and perhaps more are recorded than actually exist; for the shell will take upon itself the regularities or irregularities of the body to which it is attached. Thus on a Pecten, an individual will become striated like that Pecten through both valves, while another of the same species is smooth if adherent to a comparatively smooth body. M. Rang observed this frequently on the shores of the Mediterranean, and both Mr. G. B. Sowerby and M. Deshayes make the same observation.

---

* M. Deshayes (last edition of Lamarck) erroneously attributes the establishment of this genus to Mr. Sowerby. The error is perpetuated in the useful 'Conchological Manual' of Mr. G. B. Sowerby, Jun.

The number of species recorded by M. Deshayes in his tables is ten living and eight fossil (tertiary), and of species both living and fossil (tertiary), two, viz. *Anomiæ Ephippium* and *Electrica*.

In the last edition of Lamarck only nine species (recent) are mentioned, and but one fossil only (*A. tenuistriata*); indeed the specific names of some of the fossils noticed in the tables, *costata*, *dubia*, and *striata*, recal to the observer the remarks made by zoologists touching the varied nature of the surface of these shells according to accidental circumstances.

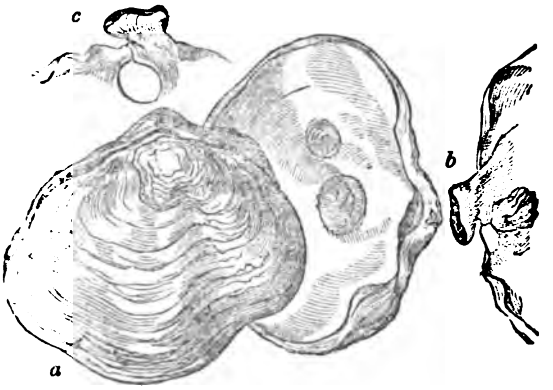
The fossils are found in the crag and London clay, and in the marine formations above the chalk in France.

Lamarck considered the animal of *Anomia* (*Echion* of Poli) as closely allied to that of the *Oyster* in its organization; but M. Deshayes observes that he does not agree in opinion with those zoologists. The *Anomiæ*, he thinks, furnish very interesting materials for study, and he believes that they approximate to the *Terebratulæ*, at least as much as the *Oysters*, and may probably be animals belonging to two groups, and serving as the passage from one to the other. If this be so, he adds, the genus would not be greatly changed in its methodical position; for if Cuvier and his imitators have separated these genera too widely, Lamarck and some others, following the inspiration of Linnæus, have approximated them as much as their still small knowledge of the animals would permit.

Example, *Anomia Ephippium*.

Description.—*Shell* suborbiculate, rugoso-plicate, waved, planulate, with an oval foramen, whitish or yellowish, often reddish yellow, below. One of the largest species.

Localities.—British Channel; Mediterranean; Atlantic Ocean.



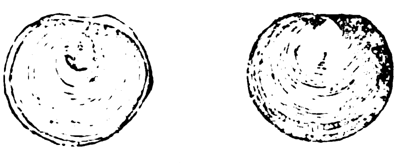
Anomia Ephippium.

a, valves closed; *b*, open to show the hinge; *c*, hinge of attached valve and the bony appendage.

Bony appendage of Anomia Ephippium adhering to rock.

a, the bony part that goes through the opening of the shell; *b*, the surface which is attached to external objects.

M. de Blainville records a species, *Anomia squamata*, which has not this bony appendage, and which he says is fixed by the valve itself. This so-called species however, which should be *Squamula*, is in Mr. G. Sowerby's opinion nothing more than *An. Ephippium* in a very young state before the appendage is ossified. In this opinion we concur. [SPONDYLIDÆ.]



Anomia squamata.

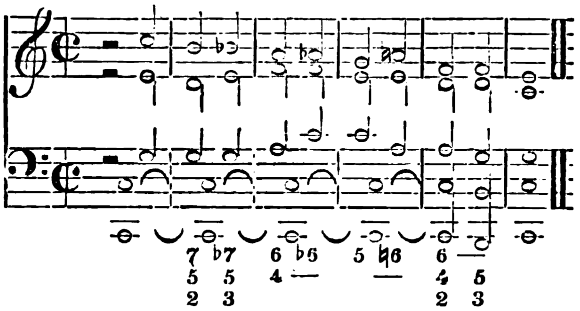
PECTU'NCULUS. [POLYODONTA.]
PECULIAR. [WILL.]

PEDAL. In musical instruments Pedals are of two kinds:—1, those keys which are acted on by the feet of the performer; 2, the levers acting on the swell of the organ, and on the stops; and also those of the piano-forte and harp, the uses of which are too well known to require explanation.

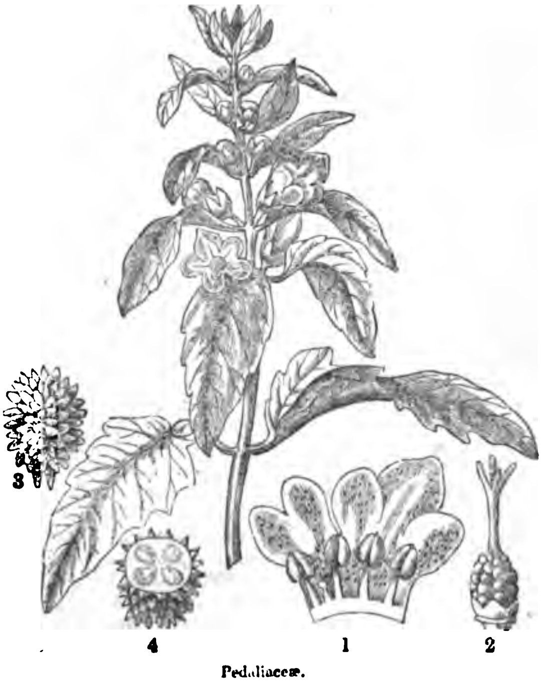
The Pedals, or foot-keys, of the organ were invented in the fifteenth century, by a German named Bernhard; but it was long before they had travelled beyond the confines of the country to which they owed their birth; and, strange to say, England was the last to adopt them, though the first to introduce the organ generally into the church. But by slow degrees their utility and importance were discovered and acknowledged, and now no organ, except of small dimensions, is built without these most desirable auxiliaries, and no organist is esteemed who is not tolerably well skilled in the use of them. [ORGAN.]

PEDAL-BASE (or *Pedale*), in music, is a base which remains stationary on one note, while the other parts continue moving and forming various chords, all of which, however, must be related to the holding note, according to the laws of harmony.

Example:—



PEDALIACEÆ, a small natural order of monopetalous Exogens, very nearly related to the Verbenaceous order, having like it irregular and usually didynamous flowers and a few seeded 2- or 4-celled fruit; but differing in having the radicle directed towards the base instead of the apex of the fruit. From Bignoniaceæ, with which they are more generally compared, their wingless seeds offer the principal distinction. They are all exotic tropical herbaceous plants, with opposite leaves and axillary flowers, and are of little known use, with the exception of the genus Sesamum, whose seeds afford a bland oil not inferior, when fresh, to that of the olive. [SESAMUM.]



Pedaliaceæ.

A shoot of Josephinia imperatricis in flower. 1, The corolla laid open; 2, the pistil; 3, the ripe fruit; 4, a transverse section of the latter.

PEDEE, River. [CAROLINA, SOUTH.]

PEDESTAL. [COLUMN.]

PEDE'TES. [MURIDÆ, vol. xv., p. 513.]

PEDICEL. [PEDUNCLE.]

PEDI'CULUS, according to Linnæus, a genus belonging to the Insecta Aptera. These insects, commonly called lice, form the order Anoplura of Dr. Leach, and Parasita of Latreille, so called from their parasitic habits, many mammals, if not all, and perhaps all species of birds, being infested by them; each species of bird and mammal, it would appear, having its own peculiar species of louse, and sometimes even two or three distinct species. Latreille thus characterises this order of insects:—Their body is flattened, nearly diaphanous, and divided into eleven or twelve distinct segments, of which three belong to the trunk (or thorax), each bearing one pair of legs. The first of these segments frequently forms a sort of thorax (or rather prothorax). The stigmata are very distinct. The antennæ are short, equal, composed of five joints, and frequently inserted in a notch. There are one or two small ocelli on each side of the head. The legs are short, and terminated by stout claws, or two opposing hooks, which enable these animals to cling with great facility to the hairs of quadrupeds or the feathers of birds, whose blood they suck, and on whose body they propagate and pass their lives. They attach their ova to these cutaneous appendages, and multiply excessively, one generation succeeding another with great rapidity. Particular and unknown causes facilitate their increase to an astonishing degree, the *P. humanus*, under such circumstances, producing in man what is termed the *morbus pediculosus*. Their movements are slow.

Three species of lice are said to infest the human subject: the *P. humanus*, which inhabits the bodies and garments, and is known by the name of the body-louse; the *P. cervicalis*, or *P. humanus capitis* of De Geer, which inhabits the head of man, and particularly children; and, lastly, the *P. pubis* of Linnæus, which constitutes Leach's genus *Phthirus*. This species inhabits the eyebrows, &c., and is commonly known by the name crab-lice.

The following are the principal genera into which the Pediculi are divided:—

In *Pediculus* proper the mouth, which is in the form of a snout, consists of a very small tubular mammilla situated at the anterior extremity of the head; the tarsi are composed each of a joint almost equal in size to the tibia, and terminated by a strong claw, which folds over a projection, and fulfils the function of a forceps; the thorax is composed of three distinct equal segments. The *P. humanus* and *P. cervicalis* belong to this genus.

The genus *Phthirus* differs from Pediculus in having the body wide and rounded, the thorax very short and confounded with the body: the anterior feet are simple, and the two hinder pairs are didactyle.

The *Pediculus* of the hog has the thorax narrow and distinct from the abdomen, which is very broad; it constitutes, according to Leach, the genus Hæmatopinus.

The *Nirmi* (*Nirmus* of Hermann, Leach, &c., and *Ricinus* of De Geer) have the mouth situated beneath the head, and composed of two lips and two hook-like mandibles; their tarsi are very distinct, and terminated each by two equal hooks. Latreille says that the species of this group, with one exception, that of the dog, are exclusively confined to birds.

PEDIGREE. A pedigree is a tabular view of the members of any particular family, with the relations in which they stand to each other; together, usually, with some slight notice of the principal events of the life of each, as the time and place of birth, marriage, death, and burial, the residence, the profession, or rank of the principal person named in it, and public offices held by him. Sometimes these are accompanied by reference to evidence of the fact stated, as to inquisitions, parish-registers, monumental inscriptions, marriage-settlements, and deeds of all kinds. But when there is much of this kind of information and evidence introduced, the writing is rather called a genealogy, or a genealogical history, than a pedigree; and many pedigrees, especially those of early date, are wholly deficient of reference to evidence for proof of the things stated in them, and contain rarely dates or anything more than the mere names of the parties who occur in them. They appear to be the summaries, or things established by certain evidences which may or may not now accompany them, in respect of descents and relationships.

Some fanciful explanations have been given of the word. But perhaps the true etymology may be that which refers it to the Latin *pedes graduum*, the word *pes*, or *pedes*, being much used in the law Latin of the middle ages to denote *summaries*, or the ultimate result in any transaction, as in *pedes finium* and *pedes compoti*. So that a pedigree is, as it were, a *total* of information or evidence respecting descents and kindredships.

The Scripture genealogies, as they are called, are so many pedigrees, but with this difference from the proper idea of a pedigree, that they are not tabular, but narrative.

Tabular genealogies, or pedigrees properly so called, are not of very frequent occurrence in the writings of the middle ages. But they are sometimes found in public records, and in the evidences of private families, or entered in the chartularies of the monastic foundations. They are generally short, containing for the most part only such matter as was wanted for the exhibition of some particular claim of right. But at about the beginning of the sixteenth century, when the College of Heralds began to pay much attention to the genealogy of the English families in reference to their claims to dignities and to the distinction which the right to armorial insignia gives, many pedigrees were compiled, and in the course of that century the heralds obtained copies of all such accounts of the English families of any distinction as could be supplied to them, and made such accounts matter of public record by entering them in the books which contain the record of their official proceedings. To obtain information of this kind, it was the practice of the heralds of that century, and it continued to be their practice till about the year 1680, to visit the various counties of England from time to time in turn, and to collect from the mouths of the principal persons of each county what they knew of the changes which had taken place in the [illegible] since the time of the preceding visitation, or what account could be given of themselves by families who had recently stepped into the rank of gentry, or who had become recently settled in the county. The pedigrees thus collected are in the visitation books at the College of Arms, and form a vast body of this species of information highly important to those who are studying critically the biography of the distinguished persons of the English nation.

Besides this grand collection of pedigrees, there are many similar collections made by private persons, or by the heralds themselves in their private capacity. Many such collections are in the library of the Heralds' College; others are in the British Museum; others in the hands of private persons. Copies of the visitation books are also often to be found. The largest collection of copies is in the British Museum, though copies of some of the best visitation books are not in any of the collections in that depository. There are many copies in the libraries of Queen's College, Oxford, and Caius College, Cambridge.

Since the visitations were discontinued, there has been no official and regular collection of pedigrees. But there has been a continual addition made to the pedigrees which are on record in the visitation books by the entry in the books of the Heralds' College of their pedigree by particular families. In some cases, as of peers, this is compulsory. When arms are granted or dignities conferred, it has been usual for families to record in the college what they know of their descent and alliances. But the books are open to any [illegible] family, who may, at a moderate expense, enter a pedigree showing the existing state of the family, and whatever is within the recollection of the older members of it, or can be proved by sufficient evidence. The entries thus [illegible] made are matter of record, and contain information which is often very interesting to the posterity of the persons who occur in them, and may be of importance in protecting rights which belong to them.

The authors of the books of topography have done something to supply the loss of information of this kind which has been sustained by the disuse of the visitations, such works usually containing notices of the families who have possessed the more important interests in the district to which the work relates.

PEDIMENT. [CIVIL ARCHITECTURE.]

PE'DIPES, Adanson's name for a genus of [illegible] shells belonging to the family *Auriculacea* of M. de Blainville and *Colimacea* of Lamarck.

Generic Character.—Animal furnished with [illegible] tentacles, implanted vertically on the head and divergent; eyes oval and situated within and at the base of the tentacles, but elliptical, divided into two portions by a wide transversal furrow; mouth furnished with an upper piece corresponding to a lingual mass armed with small hooks.

Shell globular or oval, thick; summit projecting but little; last whorl of the spire larger than all the others united; aperture long, oval, or linear, with disunited borders; columella solid, furnished with two projecting laminæ; a third very much elevated on the convexity of the penultimate whorl; external lip trenchant and furnished sometimes with small ribs within.

Hitherto two recent species only are known; they are small.

Example, *Pedipes Adansonii*. See Adanson, *Senegal*, t. 1, f. 2.

PEDLAR. This word is said by Dr. Johnson to be a contraction from *petty dealer*, formed into a new term by long and familiar use; and a pedlar is defined by him to be 'one who travels the country with small commodities.' The same writer defines a *hawker* to be 'one who sells his wares by proclaiming them in the street.' In legal understanding however a hawker is an itinerant trader, who goes about from place to place, carrying with him and selling goods; and a pedlar is only a hawker in small wares. In the various acts of parliament which impose duties upon them and regulate their dealings, they are always named in conjunction as hawkers and pedlars; and no distinction is made between them.

It has been for more than a century the policy of English law to consider the conduct of trade by means of fixed establishments as more beneficial to the public than that of itinerant dealers; and it cannot be denied that the local trader being better known and more dependent upon his character than one who continually travels from place to place, there is a greater security for the respectability of his dealings. In conformity with this policy, statutes have been passed from time to time, obliging hawkers and pedlars to take out licences and to submit to specific regulations and restrictions, which are supposed to protect the resident trader as well as the public from unfair dealing. These reasons however have been given *ex post facto* to justify the laws; for the statutes which originally required licences for hawkers and imposed these duties appear to have merely contemplated a means of increasing the revenue. (8 and 9 Will. III., c. 25; and 9 and 10 Will. III., c. 27.)

The provisions by which the licences to hawkers and pedlars are now regulated are contained in the statute 50 George III., c. 41. By that Act, the collection and management of the duties on hawkers and pedlars in England was given to the commissioners for licensing and regulating hackney coaches; but this duty has since been transferred to the commissioners of stamps by the 75th section of the statute 1 and 2 Will. IV., c. 22. By the provisions of the latter statute, 'all the powers, provisions, regulations, and directions contained in the statute 50 George III., c. 41, or any other act relating to the duties on hawkers and pedlars, are to be enforced by the commissioners of stamps; and all the powers, provisions, regulations, and directions, forfeitures, pains and penalties imposed by any acts relating to the management of duties on stamps, so far as the same are applicable to the duties on hawkers and pedlars, are declared to be in full force and effect, and are to be applied and put in execution for securing and collecting the last-mentioned duties, and for preventing, detecting, and punishing all frauds, forgeries, and other offences relating thereto, as fully as if they were repeated and specially enacted in the statute 1 and 2 Will. IV., c. 22.' The duty of granting licences to hawkers and pedlars and enforcing the law against such persons is now therefore entrusted to the commissioners of stamps; the particular conditions and regulations under which such licences are to be granted being contained in the above-mentioned statute 50 George III., c. 41.

Before a licence is granted to a person desirous of trading and travelling as a hawker or pedlar, the applicant must produce to the commissioners of stamps a certificate, signed by the officiating clergyman and two householders within the parish in which he resides, attesting that he is of good character and a fit person to be licensed. Upon this certificate being given, the commissioners grant the licence, which is only in force for one year, and the party who receives it is subject to a duty of 4*l.* per annum, if he travels on foot or with [illegible] alone, and an additional duty of 4*l.* per annum if he travels with a 'horse, ass, mule, or other beast bearing or drawing burthen;' and these duties are to be paid at the time of receiving the licence. All persons who act as hawkers or pedlars without such a licence are liable to a penalty of 40*l.* Among other regulations, the hawker or pedlar is required by the Act to 'cause to be written in large legible Roman capitals, upon the most conspicuous part of every pack, box, bag, trunk, case, cart, or waggon, or other vehicle in which he carries his goods, and of every room and shop in which he trades, and likewise upon every handbill or advertisement given out by him, the words "Licensed Hawker," together with the number, name, or other mark of his licence;' and in case of his omission so to do, he is liable to a penalty of 10*l.*; and every unlicensed person who places these words upon his goods is liable to a penalty to the like amount. A hawker and pedlar travelling without a licence, or travelling and trading contrary to or otherwise than is allowed by the terms of his licence, or refusing to produce his licence when required to do so by inspectors appointed by the commissioners, or by any magistrate or peace-officer, or by any person to whom he shall offer goods for sale, is liable in each case to a penalty of 10*l.* A person having a licence, and hiring or lending it to another person for the purpose of trading with it, and also the person who so trades with another's licence, are each liable to a penalty of 40*l.* A hawker or pedlar dealing in or selling any smuggled goods, or knowingly dealing in or selling any goods fraudulently or dishonestly procured, forfeits his licence, and is for ever afterwards incapacitated from obtaining or holding a new licence. By the stat. 48 Geo. III., c. 64, s. 7, if any hawker or pedlar shall offer for sale tea, brandy, rum, Geneva, or other foreign spirits, tobacco, or snuff, he may be arrested by any person to whom the same may be offered, and taken before a magistrate, who may hold him to bail to answer for the offence under the excise laws.

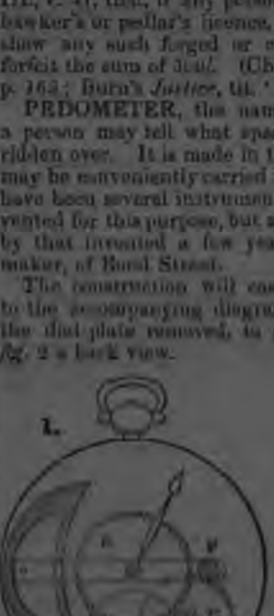
By the provisions of the statutes 29 Geo. III., c. 26, s. 6, and also of 50 Geo. III., c. 41, s. 7, no person coming within the description of a hawker or pedlar can lawfully, either by opening a shop and exposing goods to sale by retail in any place in which he is not a householder or resident, or by any other means, sell goods either by himself or any other person by outcry or auction, under a penalty of 50*l.*

It is further provided by the 15th section of the 50 Geo. III., c. 41, that, if any person shall forge or counterfeit any hawker's or pedlar's licence, or travel with, or produce, or shew any such forged or counterfeited licence, he shall forfeit the sum of 300*l.* (Chitty's *Commercial Law*, vol. ii., p. 162; Burn's *Justice*, tit. 'Hawkers.')

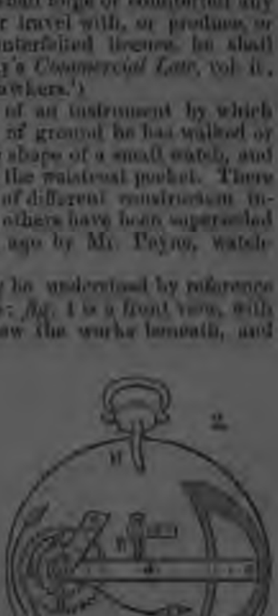
PEDOMETER, the name of an instrument by which a person may tell what space of ground he has walked or ridden over. It is made in the shape of a small watch, and may be conveniently carried in the waistcoat pocket. There have been several instruments of different construction invented for this purpose, but all others have been superseded by that invented a few years ago by Mr. Payne, watchmaker, of Bond Street.

The construction will easily be understood by reference to the accompanying diagrams: *fig.* 1 is a front view, with the dial-plate removed, to shew the works beneath, and *fig.* 2 a back view.

1.



2.



Motion is communicated from the traveller to the machinery of the pedometer by means of a horizontal lever L, *fig.* 2, which is furnished with a weight at one end and a pivot or axle at the other; under the lever is a spring S, which keeps the lever when at rest close up to the regulating screw R; this spring is so arranged as to be only just sufficiently strong to overcome the weight of the lever and to prevent its falling downwards.

When the body of the traveller is raised, either by the spring of his foot or the motion of his horse, the lever is impelled downwards by the jerk, and immediately returned to its place by the spring, and so long as the motion is continued the lever is constantly in a state of vibration. Fixed on the axis, X, of the lever, and moving with it, is a small ratchet-wheel, A; beneath this is another and larger ratchet-wheel, B, which fits on the same axis, but is not attached to it. These two wheels are connected together by a ratchet or pall, in such a manner that when the lever falls, both wheels are moved forward one or more teeth, but when the lever rises again by the force of the spring, S, the larger rachet-wheel, B, is held stationary by the ratchet or pall, P. This wheel, B, is connected with a series of toothed wheels and pinions, C D E (*fig.* 1.), by means of a pinion, F, fixed on its under surface. The centre wheel, E, carries a hand or index, which points to the figures upon the dial-plate to denote the number of miles passed over.

These instruments are generally made to register ten miles, but that of course depends on the number and relative size of the wheels between the lever or motive power and the index; by placing an extra pinion and wheel in the same manner as for the seconds hand of a watch, and making the wheel with ten times the number of teeth contained in the pinion, you get a second register, which will mark one division for every ten passed over by the larger index hand; the pedometer will then register a hundred miles. The accuracy of the instrument depends upon the proportion which the vibrations of the lever bear to the divisions on the dial-plate, and this can be altered by the small regulating screw, R (*fig.* 2), placed above the lever.

It is necessary that the pedometer should be carried in such a position that the lever shall be always as near as possible horizontal: for this purpose a small hook, H, is placed on the pendant or handle, by which the instrument may be suspended in the pocket.

With a slight difference of construction, this pedometer may be adapted to carriage travelling. For that purpose the lever must hang perpendicularly, and it does not require any regulating screw, but may vibrate backwards and forwards like a common pendulum: this is rendered requisite on account of the motion of the carriage being in the opposite direction to that of the body of a horseman or pedestrian, the former being backwards and forwards, while the latter is upwards and downwards.

The works of the pedometer may be attached to a watch, the index being placed in the dial-plate, in the same manner as that of a second's hand.

PEDUM. [PECTINIDÆ]

PEDUNCLE is that part of a plant which is called the stalk of the flower; it is not however, like the petiole with respect to the leaf, a component part of the flower, but is in reality a branch, usually of an ephemeral nature, and consisting of a single internode or of several; in the latter case it bears bracts, which indicate the station of the nodes, and which occasionally produce other branches from their axils; when this happens, such secondary branches are named *pedicels*. The naked *scape* of botanists, such as is found in the hyacinth, is in reality nothing but a peduncle which rises immediately from the bulb, and whose first internode is exceedingly long.

PEEBLESSHIRE, or TWEEDDALE, a county of Scotland, bounded on the north by Edinburghshire, on the south by the shires of Selkirk and Dumfries, on the east by those of Selkirk and Edinburgh, and on the west by Lanarkshire. It is situated between 55° 24′ and 55° 50′ N. lat., and between 2° 45′ and 3° 33′ W. long. Its greatest length from north to south is 30 miles, and greatest width from east to west rather less than 22 miles. The area has been variously computed at 251,320 acres (Armstrong, *Companion to Scotch Atlas*), 229,778 acres (Findlater, *View of the Agriculture of Peebles*), and 241,185 acres (*New Statistical Account of Scotland*), the differences between which may in some measure be accounted for from the circumstance that the boundary of the county in some parts is very irregular and ill-defined, particularly the south-eastern portion, where it is doubtful whether a considerable tract of country belongs to this county or to Selkirkshire.

The general elevation of Peeblesshire exceeds that of any other county in the south of Scotland. The least elevated part in the county is near where the Tweed crosses the eastern boundary, which is between 400 and 500 feet above the sea-level. The most mountainous parts extend from the south-east to the south-western extremities of the county, including the sources of the Clyde, the Tweed, and the Annan, the courses of which rivers indicate a general decline in the surface of the lowlands from this part of the country. The only habitations to be seen throughout the dismal mountain-range are the shepherds' cottages, few number and widely scattered. On the north-east a [illegible] ridge of mountains separates this county from Edinburghshire; and on the north-west it is separated from the same county by the Pentland Hills, among which the North Esk, the Leith Water, the Medwin (a tributary of the Clyde), and the Lyne (a tributary of the Tweed, which gives name to the town and parish of Linton), have their rise. The principal elevations are Culterfell and Cardon, in the parishes of Kilbucho and Glenholm, the summits of each of which are more than 2400 feet above the sea-level; Dollarlaw (2[illegible] feet, according to Armstrong), in the parish of Manor, whence there is an extensive view of the Lothians, Berwickshire, and the English borders; Hell's Cleugh (2[illegible] feet, according to the same authority), in the parish of Kirkeird; and Hartfell (2635 feet) and Broadlaw (2741 feet) in the parish of Tweedsmuir. The hills and mountains of the last-mentioned parish afford good pasturage for sheep and black cattle; and they are of such easy access, that the peat upon their summits, whence the cottagers are supplied, is brought down in common carts.

The Tweed, the only river of the county, takes its rise from a spring in the upper part of the parish of Tweedsmuir, situated 1500 feet above the sea-level, and upon the same hill from whose base issue the rivers Clyde and Annan. Its course within the county is north east by north until it reaches the town of Peebles, after which its course is nearly due east, crossing the northern parts of the counties of Selkirk and Roxburgh; and after separating Berwickshire from Northumberland, it falls into the German Ocean about half a mile below the town of Berwick, and about 1[illegible] from its source. In the first 20 miles of its course it descends through a height of 1[illegible]00 feet. It is remarked in the 'New Statistical Account of Scotland,' that so long as this river flows in a north-east direction, the hills on both sides equally healthy for sheep-pasture, and the disease called 'illness' is almost unknown; but so soon as it takes easterly direction, the sheep on the right bank become subject to that disease, and also to what is called 'louping-ill,' to an extent tenfold greater than what takes place among those on the hills of the left bank, which have a southern aspect. The numerous rivulets which intersect the county all tributaries of the Tweed. The chief of these are the Lyne, already mentioned; the Peebles or Eddlestone, which falls into the Tweed at the town of Peebles; the Leithen; the Manner; and the Quair, which last falls into the Tweed near the seat of the Earl of Traquair. From the hilly character of the country through which they flow, these rivers are subject to sudden inundations, which sometimes occasion considerable injury to the adjoining lands. Most of these streams, and particularly the Manner, contain, during season, both salmon and trout. Eddlestone Loch is a small lake in the north-east part of the county, from which South Esk takes its rise. It abounds with pike, perch, and eels, and is the resort of large flocks of wild fowl during summer.

With the exception of the parishes situated on the right bank of the Tweed, the county is well intersected by roads which, though inconveniently narrow, are for the most part kept in good repair. The principal are those connecting Edinburgh and Moffat, and Lanark and Kelso. The former enters the southern part of the county near the source the Tweed, and winds through the valley of that river a single line for about 15 miles, when it separates into branches, one passing through Broughton, the other through Eddlestone, which again meet upon the borders of Edinburghshire. The road from Lanark to Kelso, which is the means of communication with Glasgow, crosses the northern part of the county from north-west to south-east, passing through the town of Peebles. The tolls of the county 1834 were let for 3351*l*., including the sum of 360*l*. paid by the post-office for the mail-coaches.

The climate is keen, but less severe than that of Edinburgh. The mean annual temperature of Tweedsmuir, the most elevated parish in the county, was 45° in 18[illegible]; the mean height of the barometer at the town of Peebles, which is 535 feet above the sea-level, is 29·2 inches in summer and 29 inches in winter; and the indications of a rain-gauge kept at the same place, upon an average of seven years, [illegible] an annual fall of 29·72 inches. The fogs so often met with in the Lothians seldom extend into this county.

The prevailing rock is whinstone, of which there are some excellent quarries in the vicinity of the town of Peebles, and from which the town has been chiefly built; but that which is found in other parts is, from its laminated structure, unsuitable for building. This whinstone, as it is commonly called, is a coarse argillaceous schist, the greywacke of mineralogists. In this county, in its simplest state, it is a fine clay-slate, of a dark lead colour, some of it so laminated as to afford roofing-slate. In the parish of Stobo it has been worked for that purpose for a long period. Another sort is a fine greywacke slate consisting of an argillaceous base intermixed with sand and mica. In a still coarser state it contains quartz gravel. White and red freestone are common in the north, and both coal and limestone have long been wrought at Carlops, in the parish of Linton. The village of Innerleithen is now much frequented on account of the water of a spring which has long been celebrated for the cure of old wounds, diseases of the eyes, and other complaints. Within a few years, Lord Traquair, the proprietor of the village, has erected a neat and commodious building whence the waters are now supplied to the visitors.

Of the 241,180 acres which, according to the 'New Statistical Account,' constitute the area of the county, the portion under cultivation, or occasionally cultivated, does not exceed 34,762 acres, or not quite one-seventh. Of that which is never cultivated, not more than 8349 acres are supposed susceptible of cultivation, and there are 6755 acres of underwood. In the united parishes of Broughton, Glenholm, and Kilbucho, where one-fourth of the entire surface is under the plough, the value of the arable land averages 25s. per acre (*Scotch acre, we suppose*). In breaking up the lea or pasture-ground which has lain for some seasons, the rotation of crops is:—'1st, oats or peas; 2nd, turnips or potatoes; 3rd, barley, among which rye-grass and clover-seeds are sown; 4th, hay.' The land then remains in pasture for a few years, or a fresh rotation commences. 'Leases are generally granted for nineteen years, but farms purely of the store kind are let for *fourteen years only*. The chief hindrances to improvement are, the non-residence of the proprietors; the distance from markets, coal, and lime; and to these may be added strict entails, which fetter both the landlord and the tenant.' (*New Statist. Acc.*, p. 92.) Enclosures and planting are on the increase, and improvements in agriculture meet with ready adoption. The buildings upon most of the farms of any importance have been entirely renovated within the last thirty years. The black-faced sheep were exclusively reared till the commencement of the present century. Since then the Cheviot breed has been introduced, and has increased so rapidly, that even in the most exposed situations their number now exceeds that of the other kind. The practice of smearing the sheep with grease is still general; but instead of tar, which was formerly employed, train or cocoa-nut oil is usually substituted. It prevents the wet penetrating to the skin of the animal, and is supposed also to increase the quality of the wool. The arable farms vary in extent from 40 to 200 acres; the sheep farms from 500 to 4000 acres. (Findlater, p. [illegible]) The total number of sheep in the county in 1834 was estimated at 102,000.

The county is divided into sixteen parishes, the aggregate population of which, in 1831, was 10,578 persons. These were distributed among 2512 families, of whom 790 were employed in agriculture, 560 in trade, manufactures, and handicraft, and 670 were not included in these two classes. The inhabitants generally are now said to be distinguished for neatness and cleanliness, both in their houses and persons, though formerly it was far otherwise.

From the summary of the returns relative to the state of education in Scotland in 1834, printed by order of the House of Commons in 1837, it appears that, allowing for defective returns, the number of children in the county under five years of age who had been already taught or were then learning to read, was 86; of those between five and fifteen years already taught or then learning to read, the number was 1848, or rather less than two-thirds of the total number of children between those ages; and of those between five and fifteen already taught or then learning to write, the number was 1100. There were in all sixteen parochial schools, conducted by 17 instructors. The greatest number attending these schools during the half year ending Lady-day, 1834, was 467 boys and 391 girls; and the least number during the same period was 304 boys and 252 girls. The aggregate receipts of the parish schoolmasters in the year ending with Lady-day, 1834, amounted to 853l. 8s. 6d., and consisted of—salaries, 494l. 9s. 10d.; school-fees, 290l. 17s. 3d.; other emoluments 68l. 7s. 7d. There were also 14 non-parochial schools, conducted by 17 instructors, and attended by from 667 to 686 children.

The only antiquities of the county are the ruins of castles or towers, erected upon the banks of the Tweed and its tributaries to frustrate the inroads of the English. The walls were of whinstone, strongly cemented, and varied from eight to eleven feet in thickness. One of these, the castle of Neidpath, now the property of the Duke of Queensberry, during the conflict between Charles II. and Cromwell made a very stout resistance against the forces of the latter. Another, in the parish of Broughton, is called, for reasons unknown, the Castle of Macbeth.

Peebles, the county town, is agreeably situated in a valley on the northern or left bank of the Tweed, at the confluence of the Eddlestone Water with that river. It is 20 miles due south from Edinburgh and 42 east by south from Glasgow. From the pleasantness of its situation and its vicinity to Edinburgh, it became at an early period the summer residence and place of rural amusement of the Scottish kings, and particularly of Alexander III., in the early part of the thirteenth century. This king is supposed to have been the founder of the *cross kirk*, now a small ruin, dedicated to St. Nicholas, a Scottish bishop, who suffered martyrdom during the persecution of Maximian (A.D. 300), and whose bones were believed to have been found upon the spot afterwards occupied by the church. To this church was attached a monastery of red friars, which was suppressed at the Reformation. After the battle of Nevill-cross (1346), in which David II. was taken prisoner by the English, the town of Peebles contributed largely towards his ransom, in consideration of which he, in 1367, created it a royal burgh. In virtue of this title it afterwards returned a member to parliament, in union with the burghs of Lanark, Linlithgow, and Selkirk, down to the passing of the Reform Act, by which Act its elective franchise is merged into that of the county. The county has returned one member since the union of the two kingdoms. The town was exclusively situated to the westward of the Eddlestone till 1545, when, having been burnt by the English, a new town was commenced on the opposite bank, and surrounded by a wall, with gates, which latter were standing in 1707. The revenue of the burgh, consisting chiefly of rents, amounts to about 643l. annually. The annual expenditure is something less. There is however a debt, which in 1833 amounted to 2426l. A provost, two bailiffs, dean of guild, treasurer, and twelve councillors constitute the town-council. The parish church, a substantial stone building, was erected in 1784. St. Andrew's Cathedral, which was formerly used as the parish-church, but of which only a small portion is now standing, was a very elegant edifice. It is supposed to have been dedicated by Jocelin, bishop of Glasgow, who died in 1199. It was converted into a stable by Cromwell's soldiers, by whom also the roof was demolished.

The bridge, which here crosses the Tweed, consists of five stone arches in the channel of the river, and three smaller arches on dry ground, for carrying off the water when the river overflows its banks. Till 1834 its width did not exceed 7½ feet. Since then it has been widened to 22 feet, at an expense of 1000l. Four fairs are held annually for the hiring of servants and the sale of cattle. The population of the burgh and parish of Peebles, in 1831, was 2750.

(*New Statistical Account of Scotland*; Findlater's *Account of the Agriculture of Peebleshire*, 8vo., Edinb., 1802; Pennecuik's *Description of Tweeddale*, 4to., Edinb., 1715; Grose's *Antiquities of Scotland*, 4to., London, 1791; Forsyth's *Beauties of Scotland*; *Parliamentary Papers*, &c.)

PEELE. [MAN, ISLE OF.]

PEERS OF THE REALM are persons in whom inhere certain high dignities with privileges appurtenant. Without meaning to decide the question whether the lords spiritual are in strictness of speech peers of the realm, the persons who fall under this description are the dukes, marquesses, earls, viscounts, and barons, and this without reference to the accident of age, an earl being as much a peer of the realm, though a minor, and consequently not admissible to some of the high privileges of his order. Ladies may also in certain cases be peeresses of the realm in their own right, as by creation, or as inheritors of baronies which descend to heirs general. The wives of peers are peeresses of the realm, and entitled, in consequence of the rank, to certain privileges.

Under the several articles DUKE, MARQUIS, EARL, VISCOUNT, and especially BARON, will be found certain observations pertaining to each distinct order of peers. On the remote origin of this order of persons, and of the privileges belonging to it, especially that great privilege of having a house, in which, in concurrence with the spiritual lords, they consider every proposal for any change in the laws and customs of the realm, and have an affirmative or a negative voice respecting it, and of being also the supreme court of judicature before whom appeal may be made from the judgment of nearly all inferior courts, great obscurity rests; as it does also on the whole of the early constitution and history of Parliament, of which the peers form so eminent a part. [PARLIAMENT.] The reports of the committee of the house of peers, which sat during several parliaments about the years 1817, 1818, and 1819, on the dignity of a peer of the realm, contain a great amount of information on these topics, but leave undecided some of the greater and more important questions connected with it.

It seems however now to be clearly established, as a part of the laws and constitution of the realm, that every peer, being of full age and of sound mind, is entitled to take his seat in the house of peers and to share in all the deliberations and determinations of that assembly; and that he has privilege (perhaps not very distinctly defined) of access to the person of the king or queen regnant to advise concerning any matter touching the affairs of the realm. These are great and eminent privileges, but they are accompanied by others which illustrate the great consequence and deference which the constitution of England allows to the possessors of this dignity. If charged with any crime, they shall not be subject to the ordinary tribunals, but the truth shall be examined by the peers themselves; they shall not be arrested in civil cases; a peer's affirmation on honour is sometimes accepted where in ordinary cases an oath is required; and scandals concerning them are peculiarly punished.

It is now also clearly established that the crown may at its pleasure create a peer, that is, advance any person to the dignity, and to any one of the five orders; but that when once advanced the peer cannot be deprived of the dignity or any of the privileges connected with it, except on forfeiture of the dignity in due course of law, and the dignity must descend, on his death, to others (as long as there are persons within the limitation of the grant), with all the privileges appurtenant to it, usually to the eldest son, and the eldest son of that eldest son in perpetual succession, and so on, keeping to the eldest male representative of the original grantee. Some deviation from this rule of descent however has occasionally occurred, special clauses having been introduced into the patent, which is the writing by which the crown declares its will in this particular, limiting the descent of the dignity in a particular way, as in the case of the creation of Edward Seymour to the dukedom of Somerset, in the reign of Edward VI., when it was declared that the issue of the second marriage of the duke should succeed to the dignity in preference to the son of a former marriage. But generally, and perhaps universally for the two last centuries, the descent of a dignity (cases of baronies in fee, as they are called, being now for a moment excluded) has been to the next male heir of the blood of the person originally ennobled; sometimes with remainders to the next male heir of his father or grandfather. There is an instance in the reign of Charles I. of a dignity of peer of the realm being granted to a person (a Lucas) and the heirs male of his body, with remainder to a brother and the heirs male of his body, with remainder to one who was an illegitimate son of the father of the grantee, and therefore, in the eye of the law, not of the blood of the grantee and the heirs male of his body.

Indeed, it being at the pleasure of the crown that these dignities originate, it is not surprising that variety should be found in the manner in which the crown has declared its intention, and precedents should be producible for deviations from the usual course. The point is of some importance, since the question is from time to time raised, whether it might not be expedient that the ranks of the house of peers should be replenished by persons who are created peers for their lives only.

It has not unfrequently happened that the crown has granted the dignity of the peerage to a person, with remainder to the female issue or to the female kindred of the grantee and their heirs, as in the case of the Nelson peerage. In these cases it has generally happened either that the party had no male issue to inherit, and that the other males of the family were also without male issue, or that there was already a dignity inheritable by the male heir of the party on whom a new dignity was conferred to descend to his female issue.

The peers who possess what are called baronies in fee are the descendants and representatives of certain old families for the most part long ago extinct in the male line, but which had in their day summons to parliament as peers, and whose dignity it has been assumed descended like a tenement to a daughter, if only one daughter and heir, or to a number of daughters as coheirs, when there was no son. This principle has been so often recognised, that it may be regarded as a part of the constitution of the peerage, and in virtue of it, if A. die seised of a barony in fee, leaving B. a daughter and only child and M. a brother, the dignity shall inhere in B. in preference to M., and shall descend on the death of B. to her eldest son. In case A., instead of leaving B. his only daughter, leave several daughters, B., C., D., &c., and no son, the dignity shall not go to M., but among the daughters; and since it is imparticipable, it is in a manner lost as long as those daughters, or issue from more than one of them, exist. But should those daughters die with only one of them having issue, and that issue a son, he shall inherit on the death of his aunts. This is what is meant by the dignity of a peer of the realm being *in abeyance:* it is divided among several persons, not one of whom possessing it wholly, none of them can therefore enjoy it. [PARCENERS.] But the crown possesses the power of determining the abeyance, that is, it may declare its pleasure that some one of the daughters or the eldest male representative of some one of the daughters shall possess the dignity, as would have been the case had there been a single daughter only; and in case of an heir thus entering into possession of the dignity, he shall take that precedence among the barons in the house of peers which belonged to the family of whom he is the representative. A female who is only a coheir of a coheir may also have the abeyance determined in her favour. This was lately the case with Mrs. Russell, now baroness De Clifford. It is out of this privilege of the crown that the peerage cases arise of which there are some before the house of lords in almost every session of parliament. A party sees reason to think that the crown may be induced to determine a certain abeyance in his favour, if he can only prove that he is the representative of one of the coheirs. This proof, which is often a troublesome and expensive process, inasmuch as it may be necessary to go back into the fourteenth or fifteenth century, is to be made to the satisfaction of a committee of privileges of the house of peers, and on the report of such committee that the claimant has shown himself in a satisfactory manner to be the proper representative of the blood of one of the coheirs of one of these antient baronies, the crown has of late years [illegible] yielded to the reasonable request. In fact, without this, in a country like ours, where lands often descend to female heirs, it would be difficult to maintain a really antient nobility.

Many of the peers who belong to the higher orders of nobility have baronies in fee inherent in them; so that if A., one of them, die, leaving a daughter being an only child, and a brother, the brother shall take the superior title, and the barony descend to the daughter and the heirs of her body. An eldest son of a peer enjoying a barony and a superior dignity is sometimes called to the house of peers in his father's barony. When this is done, it is by writ of summons without a patent of creation (it not being in fact a creation of a new dignity, but only in [illegible] of the son's possession of it), and this is the case when a barony is taken out of abeyance.

Thus the English portion of the house of peers, [illegible] of lords, for they are terms used in precisely the same sense, are the lords spiritual, that is, the archbishops and bishops, and the lords temporal, who are of one of the five orders (though many of the dukes possess dignities of [illegible] inferior kinds also, and their ancestors may have long had seats in that house in those inferior dignities before the family was raised to the dukedom; and there are other persons who have been created peers by the crown, who have been admitted into the peerage by favour of the crown in virtue of the determination of an abeyance, or who have inherited the dignity from some ancestor on whom it had been conferred.

The fullest information on all points connected with the archaeological part of this subject is to be obtained from the Reports of the Committee of the House of Lords before referred to. Biographical accounts of the more eminent of the persons who have possessed these dignities are to be found in that very valuable book, Dugdale's 'Baronage of England.' In 1709, Arthur Collins, a London bookseller, published in a single volume an account of the peers then existing and their ancestors, a work of great merit. The demand for it appears to have been great, as it was followed by other editions in quick succession. It assumed a higher character in 1735, when it appeared in four handsome octavo volumes, great additions having been made to every article. From that time there has been a succession of editions, each professing to be improvements on the preceding, and each bringing up the state of the peerage to the time when the work was printed. The best of these, which is in nine bulky octavo volumes, was published under the superintendence of Sir Egerton Brydges. But as titles become extinct, and consequently the families bearing them are left out of the peerage-books, those who wish to possess a complete account of these eminent persons must procure many of the earlier editions of the work, as well as that which, being the latest, will for the most part be called the best. There are certain minor works giving the genealogical details of the descent of the dignities, which are published almost every year.

PEEWIT. [Plovers.]

PEGANUM, from *Peganon*, the Greek name of Rue, of which three kinds are described by Dioscorides,—the garden, the mountain, and the wild. The last is said to be called *moly* in Cappadocia and Galatia, and by some *harmala*. It is remarkable that even in the present day a plant is found in the north of India, the Punjab, and Caubul, which is called *hurmul* by the natives of the above countries, and sometimes distinguished in India by the name of *Lahouree hurmul*, indicating that it was introduced from the direction of Lahore. The Persian works on materia medica in use in India give *moly* as its Greek name, according to Dr. Royle (*Illustr.*, p. 155). It is interesting to find that the plant to which these names are assigned by the natives of the country, is the *Peganum Harmala* of botanists, a fact which shows that the investigations of the West had arrived at the same conclusion as those in the East respecting the plant alluded to by Grecian authors; and this enables us to put more faith in the results of such investigations than is sometimes done. The plant which is called Syrian Rue in gardens belongs to the natural family of Rutaceae, and is of easy culture in any light soil. The seeds which were formerly in use in medicine in Europe still are so in the East, but are not possessed of any peculiar or very active properties.

PEGA'NIA. [Pulmonaria.]

PEGASUS, one of the old constellations, called by Aratus (and also by Hyginus) simply the Horse. The mythological accounts of Pegasus (a son, it was said, of Neptune and the Gorgon Medusa, though how with such parentage he came to be a horse is not stated), the creator of the fountain Hippocrene at one kick, are more than usually unconnected, and the constellation is not a whole horse, but only the head, fore legs, and shoulders, to which a pair of wings is attached; nor is there any fountain near the place, except that with which Aquarius feeds one of the fishes. The figure of Pegasus is inverted, the head being farther from the north pole than the body: the constellation is surrounded by Cygnus, Equuleus, Aquarius, Pisces, and Andromeda. There are three bright stars, α (or Markab), β (or Scheat), γ (or Algenib), which form a quadrangular figure with α Andromedae, such as cannot be mistaken when the latter constellation is known. Moreover, a line drawn through α and β points to the pole star, in a line which produced passes through the pointers of the Great Bear.

The following are the principal stars:—

PEGU was a century ago a powerful empire in the peninsula without the Ganges. The nation which established this empire is called Peguans by the Europeans, and Taleins by the Birmans; but they call themselves Mon. They inhabit the low country which extends on both sides of the river Irawaddy, from its mouth to the Galladyet Mountains (from 16° to 18° 30′ N. lat.), and from the banks of the Saluen river to the mountains of Aracan. Having attained a higher degree of civilization than most of the neighbouring nations, they extended their conquests northward along the banks of the Irawaddy, and subjected the Birmans. But this numerous and warlike people rose against them and overturned their empire. Their capital, Pegu, was taken by Alompra in 1757, every private dwelling was razed to the ground, and all the inhabitants dispersed or led into captivity. The successors of Alompra however built a new town on the same spot, which was visited in 1795 by Colonel Symes. The extent of the antient town was accurately traced by Colonel Symes by the ruins of the ditch and the surrounding wall. It appeared to have been a quadrangle, each side measuring a mile and a half. The new town occupied about one half of the area of the old town, and was fenced round by a stockade from 10 to 12 feet high; on the north and east sides it bordered on the old wall. There was then only one main street running east and west, crossed at right angles by two smaller streets. The streets were spacious and well paved with bricks, which the ruins of the old town plentifully supplied. On each side of the streets was a drain to carry off the water. The houses, according to the custom throughout the Birman empire, are raised either on wooden posts or bamboos of different heights, according to the size of the building. The *kioums*, or monasteries, and the habitations of the higher ranks, are usually elevated six or eight, and those of the lower classes from two to three feet. They are composed wholly of bamboos and mats, or sheathing boards, and indifferently thatched. No brick buildings are permitted to be erected, except those which belong to the king or are dedicated to Gaudama. It is feared that if the people were allowed to build brick houses, they might erect brick fortifications, and thus endanger the security of the state.

---

* [illegible] to be marked by [illegible].

The numerous temples were spared when Alompra destroyed the town. The most famous is the Shoe Madou (the Golden Dwelling of the God), which is 361 feet high, and consists of two terraces and a steeple. The lower and greater terrace is about 10 feet above the natural level of the ground, and forms an exact parallelogram. The upper or lessér terrace is similar in shape, and rises about 20 feet above the lower terrace. Each side of the lower terrace is 1391 feet, and of the upper 684 feet. The terraces are ascended by flights of stone steps, and on their sides are the dwellings of the rhahaans, or priests, made of boards and covered with tiles. The steeple, which is properly called the Shoe-Madou, is a pyramidal building composed of brick and mortar, without excavation or aperture of any kind. It is octagonal at the base and spiral at the top. Each side of the base measures 162 feet. This immense breadth diminishes abruptly, and the whole building may be compared in shape to a speaking-trumpet. A great variety of mouldings and ornaments in stucco encircle the building on all sides, and the whole is crowned by a *tee*, or umbrella of open iron-work, from which rises a rod with a gilded pennant. The circumference of the tee is 56 feet. Round the lower rim of it are hung a number of bells, which, when agitated by the wind, make a continual jingling. The tee is gilt. All the lesser pagodas of the town are ornamented with umbrellas of similar workmanship, which are likewise encircled by small bells.

The priests inhabit groves, in which they build their kioums, or monasteries, and instruct the boys in reading, writing, and the moral and religious duties, without receiving any remuneration, except some rice or other necessaries. The only article of consequence manufactured at Pegu is silk and cotton cloth, which the women weave with considerable skill; but no more is made than is sufficient for home consumption.

This town, which is called Bagó by the natives, is situated about 17° 40′ N. lat. and near 96° E. long., and is built on the eastern banks of a navigable river, which, about 90 miles below the town, joins the eastern or Syrian branch of the Irawaddy about 3 miles below the town of Rangoon. The tide seems to ascend in the Pegu river to the town, but at the time of Symes's visit it had no commerce.

(Symes's *Account of an Embassy to the Kingdom of Ava.*)

PEINE FORTE ET DURE. The 'strong and hard pain,' which is denoted by these words, was a species of torture used by the English law to compel persons to plead when charged judicially with crimes less than treason, but amounting to felony. It was applicable whenever the accused stood mute on his arraignment, either by his refusal to put himself upon the ordinary trial by jury, or to answer at all, or by his peremptorily challenging more than twenty jurors, which was a contumacy equivalent in construction of law to actually standing mute. This proceeding differed essentially from the 'quæstio' in the Roman law, and the torture which generally prevailed in Europe, and which, as connected with the royal prerogative, was also practised in England for several centuries, inasmuch as its object was to force submission to the regular mode of trial prescribed by the law, and not to compel testimony or the confession of a crime.

Much difference of opinion has existed upon the question whether the practice of the peine forte et dure originated with the statute usually called the Statute of Westminster 1 (3 Edw. I., c. 12), or whether it was in use at an earlier period. The latter opinion is maintained by Coke and Hale, but the former is adopted by Staundforde, Blackstone, and Barrington. In a note to Hale's 'Pleas of the Crown,' vol. ii., p. 322, Emlyn says that although the Statute of Westminster 1 speaks of this punishment rather as a thing already known than as a new introduction, there is no notice taken of it in any antient author, book-case, or record before the reign of Edward I.; and, on the contrary, he cites two curious records in the reign of Henry III., from which it appears that persons at that time arraigned for felony, and standing mute, were not put to the peine forte et dure, but had judgment to be hanged. Upon this point it is worthy of remark that the statute of Edward I. merely directs that 'such persons as will not put themselves upon inquests of felonies at the suit of the king shall be put into hard and strong prison (*soient mys en la prisone fort et dure*), as those which refuse to be at the common law of the land;' whereas the judgment of the peine forte et dure, as given in antient books, contained many particulars of suffering to be imposed on the contumacious prisoner, not mentioned in the statute. Fleta, who must have written about ten years after the date of the statute, describes the judgment to be, that 'the party shall be cast into prison and lie upon the bare ground clothed with a single garment and barefooted; that he shall have for his food only three morsels of barley-bread in two days; that he shall not have food every day, but only on alternate days; that he shall not drink every day, but that on the day when he shall have no food, water shall be given him to drink.' (Fleta, lib. [illegible] cap. 34.) It certainly seems improbable that all these circumstances should, within a very few years, have been added to the judgment warranted by the statute, if the statute had really been the origin of the practice. Mr. Reeves has plausibly suggested that the only object and effect of the statute was to apply the same compulsory process to those who refused to submit themselves to trial by jury in indictments at the king's suit, which had been previously in use to compel persons to put themselves upon antient methods of inquiry, namely, the duel, the ordeal, or the wager of law. (*History of the English Law*, vol. ii., p. 137.) The trial by jury had no doubt been much encouraged during the reign of Henry III., in opposition to the barbarous modes of trial previously used; and it is therefore by no means improbable that this statute should have contemplated the promotion of this great judicial improvement. The language of the enactment also is entirely consistent with the view of its object suggested by Mr. Reeves. On the other hand it must be acknowledged that the instances above mentioned, as cited by Emlyn, and the total silence of Glanville and Bracton, as well as of the judicial records anterior to the statute respecting such a mode of enforcing submission to the law, are adverse to this interpretation. The origin of this rude proceeding must therefore be considered as uncertain.

It appears from Fleta, and also from Britton (cap. [illegible]) that the punishment in the reign of Edward I., when the first traces of it in the history of English law appear, consisted merely of severe imprisonment, with a diet barely sufficient to prevent starvation, until the offender repented of his contumacy and consented to put himself upon his trial. A curious charter of pardon in the 31st Edw. III. (1357), published in Rymer's *Fœdera*, vol. vi., p. [illegible] recites that a woman indicted for the death of her husband, having stood mute, had been adjudged 'ad pœnam suam, ut dicitur, in quâ sine cibo et potu in artâ prisonâ per quadraginta dies vitam sustinuit viâ miraculi et quasi contra naturam humanam.' It appears therefore that at that time the sentence continued to be imprisonment only, and did not authorise the infliction of any further violence. Shortly afterwards however the practice of loading the sufferer with weights and pressing him to death appears to have become the regular course. In the 'Year Book,' 8 Henry IV. (1406), the judgment upon persons standing mute, as approved by advice of all the judges, was 'that the marshal should put them in low and dark chambers, naked except about their waist; that he should place upon them as much weight of iron as they could bear, *and more*, so that they should be unable to rise; that they should have nothing to eat but the worst bread that could be found, and nothing to drink but water taken from the nearest place to the gaol, except running water; that the day on which they had bread they should not have water, and *e contrâ*; and that they should lie there till they were dead.' Thus, although the reporter states in this case that the judgment was formerly different, the punishment now became capital, a lingering and painful death being enjoined instead of severe imprisonment to extort submission. There is no trace of any statute or royal ordinance, or of any authority besides this judicial resolution to justify a change in the mode of proceeding so material as to affect the life of the party. The form by which it was denoted was also changed from *prisone* in *peine forte et dure*; and from this period, for more than three centuries, until it was virtually abolished by the stat. 12 *Geo.* III., c. 20, (1772,) *pressing* to death continued to be the regular and lawful mode of execution for criminals who stood wilfully mute upon their arraignment for felony. The press-yard at Newgate at the present day retains its name as derived from this barbarous practice.

Blackstone, after alluding to 'the doubts that were conceived of its legality,' and 'the repugnance of its theory to the humanity of the laws of England,' states that the peine forte et dure was rarely carried into practice. (*Commentaries*, vol. iv., p. 325.) It is probable that it was not of frequent occurrence, because with this fearful punishment for contumacy before their eyes, men would naturally for the most part (as Hale says) 'bethink themselves and plead.' It is however repeatedly mentioned in the Year Books as an existing proceeding; it is stated as the law of the land by Staundforde, Coke, Hale, and Hawkins, in their several treatises on the Criminal Law, and the number of the recorded instances in which it is directly or incidentally mentioned seems to shew that it was much more prevalent than has been commonly supposed. The motive of the prisoner in standing mute and submitting to this heavy punishment was to save his attainder, and prevent the corruption of his blood and consequent forfeiture of his lands in case he was attainted of felony. In the 21st of Henry VI. (1442), Juliana Quicke, who was indicted for high treason in speaking contemptuous words of the king, had the peine forte et dure because she would not plead (Croke's *Charles*, 118); in the margin of an inquisitio post mortem of Anthony Arrowsmith, in the 40th of Eliz. (1598) are the words 'Prest to death' (Surtees's *History of Durham*, vol. iii., p. 271); and in 1659, Major Strangeways was tried for the murder of John Fussell before Lord Chief-Justice Glynn, and, refusing to plead, was pressed to death in Newgate. In the pamphlet which very minutely narrates the particulars of this execution, it is stated that the prisoner died in about eight minutes, many people in the press-yard humanely casting stones upon him to hasten his death. (Barrington's *Antient Statutes*, p. 85, note.) In still more recent times it appears from the Old Bailey Sessions Papers that at the January Sessions in 1720, one Phillips was pressed for a considerable time, until he begged to stand his trial; and at the December Sessions, 1721, Nathaniel Haws continued under the press with 250lbs. for seven minutes, and was released upon his submission. Mr. Barrington says that he had been furnished with two instances in the reign of George II., one of which happened at the Sussex assizes before Baron Thompson, and the other at Cambridge, in 1741, when Mr. Baron Carter was the judge. (Barrington's *Antient Statutes*, p. 86.) In these later instances the press was not inflicted until by direction of the judges the experiment of a minor torture had been tried by tying the culprit's thumbs tightly together with strings. It is said in Kelyng's *Reports*, p. 27, to have been the constant practice at Newgate in the reign of Charles II., that the two thumbs should be tied together with whipcord, that the pain of that might compel the culprit to plead. The adoption of this course was no doubt dictated by merciful motives, and was intended by the judges to prevent the necessity of having recourse to the peine forte et dure; but it was wholly unauthorised by law. The practice was finally discontinued in consequence of the statute 12 Geo. III., cap. 20, which provides that every person who shall stand mute when arraigned for felony or piracy shall be convicted of the same, and the same judgment and execution shall be awarded against him as if he had been convicted by verdict or confession.

PEIPUS, Lake. [RUSSIA.]

PEIRESC, NICOLAS CLAUDE FABRI DE, a counsellor of the parliament of Aix, was born at Beaugensier, in Provence, December 1, 1580. His father, Renaud de Fabri, was a counsellor of the court of aides. He received his earliest education among the Jesuits at Avignon, whence he was removed to Aix in 1595. It was during this period that his father being presented with a coin of the emperor Arcadius, found at Beaugensier, young Peiresc begged to have it; and being delighted at finding that he could decypher the inscriptions, carried it to his uncle, who gave him two more, together with some books upon medals. This incident led him to the study of antiquities, in which he afterwards distinguished himself.

In 1599 he visited Italy, in the various cities and countries of which he spent nearly three years. In 1604 he took the degree of doctor in law at Aix. In 1605 he accompanied Duvair, the first president of the parliament of Aix, to Paris, where he formed an acquaintance with De Thou, Isaac Casaubon, Papire Masson, Nicolas le Fevre, the brothers St. Marthe, Bongars, and Francis Pithou; and in the following year came in the suite of La Boderie, the French ambassador, to England, where he was graciously received by King James. He visited Oxford; and formed an intimacy with Camden, Sir Robert Cotton, Sir Henry Savile, and other learned men. From England he passed over to Holland, and through Antwerp and Brussels back to Paris.

In 1618 he procured a faithful copy and published a second edition of the 'The Acts of the Monastery of Maren in Switzerland,' in defence of the royal line of France against the title of succession of the Austrian family to the French crown.

Peiresc was a liberal patron of letters; Bayle gave him the title of 'le procureur général de la littérature;' and the authors of his life shew how imperfect the labours of Scaliger, Holstenius, Saumaise, Sicard, and Kircher would have been, unaided by the literary treasures which he procured for and presented to them. It was at his instigation that Grotius undertook his great work 'De Jure Belli et Pacis.'

The multiplicity of his engagements and the extent of his correspondence prevented Peiresc from finishing any considerable work. He left behind him, besides some of his own composition, a great number of manuscripts, antient and modern, on local history and antiquities, mathematics, astronomy, the medallic science, languages, &c. A catalogue of these, in number more than seven hundred, is preserved among Sir Hans Sloane's Manuscripts in the British Museum, No. 707.

Of his writings there have been published forty-eight Italian letters addressed to Paul and John Baptist Gualdo in the 'Lettere d'Uomini Illustri;' a considerable number among those of Camden published by Smith; and a long and learned dissertation on an antient tripod found at Frejus in the 'Mémoires de Littérature et de l'Histoire,' by Desmolets, in 1731. A considerable number of Peiresc's inedited letters were of late years communicated from time to time to M. Millin for his 'Magazin Encyclopédique,' by the president Fauris de Saint Vincens, who again published them separately, in five different tracts or portions, 8vo., Paris, 1815.

Peiresc died in the arms of his principal biographer, Gassendi, June 24th, 1637. He is stated to have purchased more printed books than any man of his time, yet the collection which he left was far from large. As fast as he purchased books and manuscripts, he made presents of them to learned men, to whom he knew they would be useful. His remaining library was purchased by the Collége of Navarre.

(*Vita Nic. Claudii Fabricii de Peiresc*, à Petro Gassendi, 4to., Par., 1641, transl. into Engl. by W. Rand, 8vo., Lond., 1657; Moreri, *Dictionn.*; Chalmers's *Biogr. Dict.*, vol. xxiv., p. 252-257; *Biographie Universelle*, tom. xxxiii., p. 254-261.)

PEKEA is the name given by botanists to a plant inhabiting Guiana, and furnishing the Saouari or Sawarra nuts of the shops, a very different fruit from that to which the name of Saouari is given in Guiana. This Pekea comprehends two species, the *butyrosa* and *tuberculosa*: the former is unknown in this country; the latter, which yields the fruit in question, is a very large tree inhabiting the woods of Guiana, where it is called Tata-youba by the Garipon Indians. It has opposite digitate leaves, whose leaflets are oval, smooth on the upper side, but white with down beneath; the terminal leaflet is said to be 8 inches long by 3½ in breadth, while those at the sides are much smaller. The flowers are unknown. The fruit consists of greenish compressed drupes, which adhere around a common centre, and contain a single seed of large size, covered with a brownish rugged woody shell, and containing a kernel of a soft consistence, and of the most delicate buttery quality. It is by far the best of the South American nuts that are brought to England, and much superior to our own walnuts, almonds, and filberts; but it is scarce and dear in most seasons.

Pekea tuberculosa.

PEKING, the capital of the Chinese empire, is situated near 40° N. lat. and between 116° and 117° E. long., in a level plain, which on the west of the town assumes an undulating surface, and at some distance from it rises into low hills. It is about 80 miles distant from the Great Wall.

The city consists of three parts: the Zin-tcheou, or City of the Throne; the Wailo-tcheou, or External town; and of twelve suburbs. The first is also called the Town of the Tartars, as the inhabitants are of Mongol or Mantchoo extraction; and the second, the Town of the Chinese, being entirely inhabited by Chinese. These two cities are enclosed by walls, the circumference of which is 58 li, or about 17 English miles. The suburbs extend on the east, south, and west of the walls. The walls are about 40 feet in height, and surmounted by a parapet deeply crenated, but without regular embrazures; the merlons contain loop-holes for archers. The thickness of the walls is about 20 feet at the base, and 12 across the terrepleine upon which the parapet is erected. The outside of the walls, though not perfectly perpendicular, is smooth, but the inside has a considerable bevel, the rows of bricks which form it being placed like steps, one above and behind the other, like the steps on the faces of the Great Pyramid of Egypt. In some parts there are slopes of earth, on which the cavalry can ascend the walls, on which several horsemen can ride abreast. The walls are flanked on the outside by square towers, at about sixty yards distance from each other, and projecting 40 or 50 feet from the curtain between them. Sixteen gates lead to the town. Over each gate is a watch-tower, nine stories high, and in each story are port-holes for cannon. The lowest story forms a large hall for the officers and soldiers on guard. Round the gate, on the outside, is a semicircular wall, enclosing a space about 360 feet long, which serves for a parade. In this semicircular wall there is a lateral gate, by which the troops can enter the parade without marching on the high road. A wall of less dimensions separates the Zin-tcheou from the Wailo-tcheou.

The roads leading to the city are paved with blocks of granite; the streets are not paved, but are constantly watered to keep down the dust. The principal streets vary from 140 to 200 feet in breadth, but they contain no large buildings; the houses are usually not higher than one story, and few have two stories. The streets are lined with a continuous series of shops, in which the goods are laid out with great order. The wooden columns in front of the shops are painted red, blue, and sometimes are gilt. In several places triumphal arches cross the streets. They are built of wood and consist of three handsome gateways, of which the middle is the highest and largest, and over them are three roofs richly decorated. Public edifices and also the dwelling-houses of private persons occur only in the narrow streets and lanes. Where these lanes open into the [illegible] streets there are generally gates, which are shut at night and opened only in case of need. The private dwellings do not embellish the town, as they are separated from it by walls or curtains, to prevent passengers from seeing the court into which the street-door opens. They are built of bricks, and have a roof of grey tiles.

No navigable river flows near the city. A narrow canal, called Yu-ho (imperial canal), runs through the town, but the waters are only used to feed the canals and ponds of the imperial palace. The inhabitants have wells, the water of which is however brackish, and wealthy persons procure water from wells without the town, especially from those on the north side, which are famous for their excellent water.

The buildings belonging to the emperor, as well as the temples and altars, have roofs consisting of four slopes, but all the other buildings have only two slopes. The imperial buildings are covered with yellow tiles, those of the princes with green tiles, and all the other houses with grey tiles. The temples not belonging to the emperor, and also the convents, are mostly painted red. Peking contains a great number of palaces and temples, decorated with numerous works in marble, but a considerable portion of the area of the town is occupied by squares, gardens, ponds, and even fields.

The Zin-tcheou, or City of the Throne, consists of three parts, enclosing one another. In the centre is the imperial palace, called Zun-zin-tcheou, which has the form of an oblong rectangle, and is surrounded by a high wall painted yellow, and hence called the Yellow Wall. It is about two miles and a half in circumference, and contains, in addition to several residences of the emperor, some public buildings and magazines, also extensive gardens, with canals, ponds, and fountains, planned and executed with taste. The Zun-zin-tcheou is surrounded by the Kuan-tcheou, the Imperial Town, which is seven miles and a half in circumference, and contains, among other remarkable buildings, the temple of Fo, or Shigemuni, with a statue of the god [illegible] of copper and gilt, which is more than 60 feet high. In this part of the Zin-tcheou there is a fine square called Zin-shang, near which is a beautiful hill, called Zin. The Kuan-tcheou is enclosed on all sides by what is more especially called the City of the Throne, or Zin-tcheou, in which the university buildings and those of the Russian mission are situated. The whole city is ten and one-sixth li in length, and is nine and five-sixths li wide. It is considered as a military encampment, and divided among the eight divisions of the Mantchoo troops, which are stationed there. The imperial palace does not belong to those eight sections.

The Wailo-tcheou, or Town of the Chinese, is properly only a suburb, and has been enclosed with walls only on account of the two principal altars which it contains, and on which the emperor presents his offerings. These are the Tien-tan, or Eminence of Heaven, which is round, and [illegible] two miles in circumference, and the Tee-tan, or temple dedicated to the earth, which is a square, because the ancient Chinese considered the earth to be of a square form. Within the walls enclosing the second temple, and which has a circumference of about two miles and a half, is the field on which the emperor himself every year goes to plough. In this part of Peking are the theatres, and other places of amusement, as baths, &c. It extends along the southern side of the Zin-tcheou, and is somewhat longer, but not quite so wide. It contains two Catholic convents and a mosque. In one of the suburbs east of the town is the convent of the Choshanes, in the steeple of which is a very large bell weighing nearly 1400cwt., which is heard in all parts of the town when it is rung.

The population of Peking was estimated by Staunton at three millions, but Père Hyacinthe makes it only two millions. This cannot be considered as a great population when the immense extent of the Chinese empire and its wealth are considered. Staunton, in comparing Peking with the large towns of Europe, says, 'Peking is merely the seat of government of the empire,—it is not a port. It is not a place of inland trade or manufacture. No representative diet or general states assemble there to assist, or check, or examine the measures of the crown. It forms no rendezvous for pleasure and dissipation. The chief cities of Europe owe much of their opulence, size, and population to the influx of those persons who, by the gift of their progenitors or by the favour of their prince, possess wealth without labour, and seek, in the concurrence of multitudes, for opportunities to enjoy it to the most advantage. But Peking owes little of its extent or populousness to circumstances of this nature. Most of those there have their stations regularly allotted to them, or are occupied in attending or providing for those who have. Except perhaps some of the relations of the emperor, few indeed are those whose only business is the pursuit of pleasure and the consumption of that time which others are under the necessity of employing in the performance of some public duty and in the private cares of living.'

Peking, being the seat of government, contains the great offices for the administration of the empire, which are situated, for the sake of convenience, near the southern gate of the imperial palace. The most remarkable of them is the office called Li-pou, the business of which is to consider the qualifications of the different mandarins for various offices, and to propose to the emperor their removal when they are found incapable or dishonest. The office of ceremonies, called Li-pou, has for its object the preservation of the customs or morals of the empire; and the office of public censors has to take into consideration the effect of existing laws, the conduct of the other offices, of the princes and great officers of state, and even of the emperor himself. The garrison of the town is estimated at 80,000 men.

(Du Halde's *History of China*; Staunton's *Account of an Embassy to the Emperor of China*; and *Description de Péking, traduite du Chinois en Russe par* P. Hyacinthe, *et du Russe par* F. de Pigny, Petersburg, 1829.)

PELA'GIA. Lamouroux gives this name to a small coral from the Caen oolite, ranked by Blainville among MILLEPORIDA.

PELA'GIA. [PULMOGRADA.]

PELAGIANISM, PELA'GIUS, REMONSTRANTS, and SEMI-PELAGIANS. The disputes in the earlier centuries of the Christian church, when first liberated from external violence and obloquy by its formal establishment, related to the fundamental dogma of the Trinity. Christian writers, when freed from this struggle for life, and from the task of drawing up apologies in defence of the dignity, consistency, and purity of the faith which they professed, were occupied until the commencement of the fifth century with stating and enforcing the Catholic doctrine on this head. This task accomplished by the leaders of the Eastern church (for whose speculative predilections a suitable field of labour seemed thus opened), a succession of controversies arose, of a blended dialectic and practical nature, and, for this reason, equally fitted to occupy the attention of the principal thinkers of the West. Such were the questions respecting grace, election, and predestination.

Whether the great Fathers of the church, anterior to the controversies of Augustin and Pelagius, had propounded sentiments which might be fairly considered as favourable to either party, is a doubtful question, and one, consequently, which has been the parent of much violent controversy. St. Augustin himself, as is well known, quoted the earlier fathers in support of his principles. But this asserted coincidence will hardly stand the test of a close examination. The case of St. Gregory of Nazianzum, whose sentiments were quoted by St. Augustin as identical with his own, will serve to illustrate this remark. St. Gregory of Nazianzum, according to the deliberate judgment of his biographer, was not so consistent as either Augustin or Pelagius. He appears to have held a mean between the doctrines of unqualified freedom, as laid down by Origen, and those of grace, as subsequently taught by Augustin. His theory, if carried out (for the germs only of a theory are to be found in his writings), would have led him in all probability, as an admirer of Origen, to the system of Pelagius rather than of Augustin. But precise dogmatic statements not being called for (as no theory on these subjects had been formally put forward), the sentiments of St. Gregory seem to have remained to the last an anticipation of what, in the days of the Reformation, would have been called Synergism.

This anticipated Pelagianism of the early fathers was laid as a heavy charge by some doctors within the church of England during the latter portion of the sixteenth century. We read that Elizabeth's studies in the Greek Fathers gave alarm on this ground. Hooker asks—'The heresy of free-will was a millstone about the Pelagians' neck; shall we therefore give sentence of death inevitable against all those Fathers in the Greek church who, being unpersuaded, died in the error of freewill?' Almost equivalent to this was the opinion of Jackson.

Extremes, and tendencies to extremes, beget, as is well known, the opposite errors. It may accordingly be objected to the early Anglican writers, that the remembrance of the errors from which they had been delivered was as yet too fresh to allow them to form an impartial judgment in a matter of such nicety. The opinion of a later Anglican writer may be admitted, as less exceptionable on this point, respecting the Augustinian or Pelagian tendencies of the early fathers:—

'The ancient Fathers of the church met this question, concerning the union of the Divine prescience with human freedom, wisely and most reasonably. They stood upon the proofs of God's prescience, which authentic and unambiguous prophecies supplied; they maintained the liberty of human action, without which they saw there could be no religion, and, whatever solutions or qualifications they attempted to give of the apparent difficulty subsisting in their view of the case, they sought no relief of it whatever by going to invalidate the one principle or the other—the prerogative of the Divine foreknowledge, or the responsible freedom of man's moral agency. Justin Martyr, Origen, Eusebius, all concur in this judgment, and even Augustin, when he argues most coolly, does not dissent from them.'* Previous to the fifth century, the moral incapacity and fallen condition of man, and the necessity of grace to change his nature and enable him to live aright in the sight of God, were admitted as doctrines of the church. But no controversy in connection with them having as yet arisen, they had not been treated so precisely as the subjects of the Trinity and the Divinity of Christ. The seeds of dispute may be plainly discerned in the statements put forward by various fathers on these important topics. The usual differences in tone between the theology of the Eastern and Western churches are to be observed in the course of these controversies:—the first, more directly philosophical, taking a paramount interest in the Trinitarian question; the second being chiefly directed to the effects of certain doctrines on human practice. To tax the Greek fathers with tenets equivalent to Pelagianism is unfair, although, according to Hooker and Jackson, they approached somewhat too nearly to it; but it would be an arduous task to establish their entire freedom from a leaning to that side. Such must ever be the case with regard to the recorded sentiments of the class of divines so happily designated as 'superstructure men,' whose mission was rather to set forth the fruits of a change of heart, than the means ordained of God to effect the change itself. Accordingly, some expressions of Clement of Alexandria, when speaking of the natural condition and powers of man, can be explained only by such means. The admiration of Origen evinced by Pelagius was perverted, by the jealousy of Jerome, into a proof of his heterodoxy. Anianus, a follower of Origen, employed himself during the period of his disgrace by translating some of the homilies of St. Chrysostom in order to establish the identity of the doctrines contained in them with those for which he suffered. On the other side, Tertullian and Cyprian, in Africa, and subsequently Hilary and Ambrose, asserted very different doctrines, the precursors of the controversy which at last broke out in the fifth century.

Pelagius, whose name has acquired so lasting a notoriety, was born, during the fourth century, in Britain. His ordinary appellation is a translation of that borne by him in his own country. He settled in Italy as a monk, and began to disseminate his peculiar doctrines in Rome, about A.D. 400. Accompanied by his friend and admirer Cœlestius (once an advocate, but subsequently a monk, and who from temper, talents, age, and the habits of his former profession, was better fitted to head a party than his aged and simple-hearted leader), Pelagius visited Africa and Palestine. After escaping censure from the council of Diospolis, he was subsequently condemned by Pope Zosimus (who had hitherto protected Cœlestius), and banished from Italy by an edict of the emperor Honorius, in 418. It is supposed that on his expulsion from his retreat in Palestine, which he was induced to select from the similarity of his own views with those of the Eastern church, he retired to his native country. Very little of his writings has come down to us.

---

* Davison, p. 377 (1825).

'The Pelagians,' writes Hooker, 'being over-great friends unto nature, made themselves enemies unto grace, for all their confessing that men have their souls, and all the faculties thereof, their wills and all the abilities thereof, from God.' Pelagius himself, of a cold and passionless temperament, and removed from the bustle and vices of the world in the solitude of his cloister, had not gone through the fiery trials of St. Augustin. Although fully alive to the deadly evils of Antinomianism, he fell into an error equally pernicious, when he proposed to preach, as an antidote, the limitation of the sin of Adam (in its consequences) to himself, and the power of man to 'do good works pleasant and acceptable to God,' so as to merit eternal happiness, without the aid of divine grace. Not merely the culminating points of the system of Augustin, the doctrines of irresistible and absolute predestination, were repudiated by Pelagius, but the fundamental doctrines of the gospel, of the necessity of pardoning mercy and sanctifying grace, were degraded from their proper rank in the Christian scheme, and the Atonement deprived of its essential virtues. But Pelagius was better than his system; which, under different names, has been put forward in the church, with less in the character of those by whom it was propounded, to palliate their mischievous mistakes.

Differing so widely as did the systems of Pelagius and his great antagonist, it was not difficult to foresee that attempts at compromise would hardly be successful. The church of the south of Gaul was at that time in a flourishing condition, its leaders pious and learned, and an active ecclesiastical spirit pervaded the whole body. The first attempt to reconcile these contradictory dogmas, was made at Marseille. Its supporters were consequently designated as Semi-Pelagians. They agreed with St. Augustin, in that they ascribed (*generally*) a holy life *as such* to the grace of God; but on the other hand, they approached more nearly to Pelagius, as they attributed the beginning and end, or the commencement and sum of a course of acceptable actions to the force of human merit. Its internal character, as well as the circumstances under which it originated, contributed to give it some popularity, and to rank among its defenders the names of Cassian, and the better known one of Vincentius Lerinensis. But the orthodox belief found active champions in Hilary and Prosper. To the exertions of the latter the formal document of Pope Cælestinus condemnatory of Pelagian doctrines is principally attributable.

Subsequently to the decisions of the council of Orange in 529, the system of Augustin may be considered as the established standard of orthodoxy throughout the West. But the seeds of future discussion were contained in the authoritative declarations of the church, which were studiously couched in wide terms. And the subject of predestination was treated indirectly and in general expressions, with a view to avoid controversy. The doctrine of predestination to condemnation, it is to be observed, was expressly rejected. But this temporising policy for the hope of present security proved, as usual, the parent of weakness. Various attempts were made to turn the embarrassing doctrine of predestination. The most celebrated among these is that which arose during the ninth century, with which the name of the unhappy Gottschalk is connected. The condemnations, disgrace, and punishment inflicted on this unhappy man, in consequence of his ultra-Augustinianism with regard to the doctrine of predestination, which brought upon him the hostility of the ruling Semi-Pelagian party, are well known. It is manifest however, from several treatises by the most eminent theologians of the day, as well as the decisions of the various councils and synods held in connection with this affair of Gottschalk, that ecclesiastical and orthodox leanings were on the side of Augustin and his admirer.

Thus professedly Augustinian as the spirit of Catholic theology undoubtedly was, there arises a question—by what means did the antagonist principle of Pelagianism enter so largely and actively into the church system of the middle ages? Ignorance of the real principles of Augustin was one cause, which enabled the leading schoolmen to engraft their perversions upon his doctrines. For the Pelagianism of one great doctor of the middle ages, Duns Scotus, is clear and undoubted; and the leanings of another, St. Thomas Aquinas, pure and elevated as much of his teaching undoubtedly is, and Augustinian as he has often been deemed, are found, when closely regarded, to be at least Semi-Pelagian. Most close and natural was the connection between Pelagianism and the paramount attention bestowed by the schoolmen on speculative questions in morality, to which the interests of religion were often sacrificed. The naturalism of the system of Pelagius is well known. In this also some of the leading schoolmen were his followers. In their high and unbounded admiration of Aristotle, in whom they professed to discover the best and most eligible guide to Christian truth, they left, like Pelagius, the line of demarcation between Christianity and heathenism faint and indistinct.

The modern Arminians [ARMINIUS; DORT], called also in the first instance Remonstrants, and in more homely phrase, Free-Willers, correspond very nearly in doctrine with the Semi-Pelagians above mentioned. The following may be considered as a fair statement of their opinions:—1, God elects none to salvation but on account of that faith which he foresees in them. 2, Faith and sincere obedience are made the conditions of justification and salvation, just as Adam's perfect obedience would have entitled him to eternal life; and so God reputes this imperfect obedience as perfect, having relaxed the rigour of the law upon the account of Christ's satisfaction; that God sent him to die without any particular design to save any particular persons by it, but only to redeem all men in general, and now he applies salvation to all that believe and repent. 3, That Christ so far redeemed all men, that none shall be condemned for original sin, which they admit under such qualifications as almost to annihilate its effects. The doctrine of final perseverance they totally reject.

Mention has been made elsewhere of the wicked and cruel persecutions to which the Remonstrant party were subjected in consequence of the synod of Dort. It is beyond our present object to discuss the charge imputed to their principles, of leading to Socinianism. But few theological authors of that age are to be compared to Limborch and Grotius. The latter, with all his obvious faults, for a long period was regarded as the chief of Protestant expositors.

Another and important question remains behind, as to whether the supposed sudden influx of Semi-Pelagian or Arminian principles into the church of England during the earlier part of the seventeenth century is in any way attributable to the disgust conceived towards the contra-Remonstrant or Calvinist party, the victors at Dort, and the supposed better accordance of Arminianism with the high principles then held in church and state. Some have lamented over this predominancy of Arminianism, as a falling away from the spirit and principles of the symbolical standards of the English church; some, on the other hand, have stoutly maintained the original Arminianism of this church; while others assert that the claims of the two contending parties are based upon an unfair interpretation of certain particular doctrines. 'In the year 1618,' writes Waterland, 'our divines at the synod of Dort had commission to yield upon the doctrine of universal redemption, as the doctrine of the church of England (though they were outvoted in it), which one doctrine, pursued in its just consequences, is sufficient to overthrow the whole Calvinist system of the five points.' This assertion of Waterland is corroborated by the documents published by John Hales, who was present at Dort. But these opinions we shall consider in connection with the general history of theology, and conclude the present sketch with a quotation, the kindly spirit of which contrasts strangely with the prevalent bitterness of theologians during the first half of the seventeenth century, in which this author lived. 'Finding, upon this serious search, that all doubts are not clearly decided by Scripture; that the antient church, after the age of St. Augustin, which was presently contradicted by many Catholics (as you may see in the epistles of Prosper and Fulgentius to him upon this very occasion), they have ever been friendly debated, and never determined on in any council; that in our days whole churches are here divided, either from one another, as the Lutherans from us, or among themselves, as the Romanists, amongst whom the Dominican family is wholly for the Contra-Remonstrants; that in all these several churches, some particular doctors vary in these opinions; but of all this I collect for my part, that these points are not essential Catholic verities, not essential to the faith, merely matters of opinion, problematical, of inference and argument, wherein a man may err, or be ignorant, [illegible] danger to his soul. Yet so still, that the glory of God's justice, mercy, truth, sincerity, and divine grace be not any ways blemished, nor any good ascribed to man's corrupt will, nor any evil to God's decree of providence."*

PELA'GIUS I. succeeded Vigilius in the see of Rome A.D. 555. Like his predecessor, he was involved in ecclesiastical controversy with most of the Western bishops, concerning certain theological tenets condemned by the council of Constantinople, and known in controversial history by the name of the three chapters, being supported in his view of the question by the emperor Justinian, who was fond of interfering in theological disputations. (Noris, *Dissertatio de Synodo quintâ*.) Pelagius died in the year 560, and was succeeded by John III.

PELA'GIUS II. succeeded Benedict I., A.D. 578. He was likewise embroiled in disputes concerning the three chapters above mentioned. In the meantime a council which assembled at Constantinople bestowed on the patriarch of that city the title of *Œcumenic* or 'universal' bishop, at which Pelagius was greatly offended. He died at Rome, A.D. 590, and was succeeded by Gregory I.

PE'LAGUS, De Montfort's name for a genus of *Ammonites*, whose spire is covered by the last whorl, and which have no umbilicus; *Orbulites* of Lamarck and others.

PE'LAMYS, Daudin's name for a genus of marine ophidians [HYDRUS] found in the seas of warm climates. A specimen of *Pelamys bicolor* has been picked up dead on the beach of the west coast of New Zealand.

Dr. Cantor, in his *Observations on Marine Serpents*, enters into the distinguishing anatomical characters, habits, and general conformation of this group with reference to the element in which they exist. But little attention has hitherto been given to them, on account of the danger of examining them alive, and also from their geographical position being entirely confined to the tropical seas. Dr. Cantor was stationed on the delta of the Ganges, and had, for a considerable period, very favourable opportunities of studying these ophidians, many of which were taken in the nets of the fishermen. The principal physiological point of interest established by the Doctor is the highly venomous character of all the species without exception, a fact denied by Schlegel, who states them to be harmless, an erroneous idea which is also current among the natives. Dr. Cantor gives fatal proof of this error in the death of an officer in Her Majesty's service not long ago, within an hour or two after the bite of a serpent which had been caught at sea; and from numerous experiments conducted by himself, the result of which was that fowls, fish, and other animals invariably died within a few minutes after the bite had been inflicted. (*Zool. Proc.*, 1838.)

PELARGO'NIUM is the name given by botanists to the gaily painted flowers which are usually called Geraniums in our greenhouses. The latter differ obviously from Pelargonium in having regular flowers, and in being herbaceous plants, while the genus in question consists almost entirely of shrubs with flowers as irregular as those of the Pansy. There is a large number of genuine species of this genus, chiefly inhabiting the Cape of Good Hope; and as these intermix very readily, producing in great abundance shrubs which are capable of being perpetuated by cuttings, a prodigious number of spurious species, as well as acknowledged varieties, have found their way into the writings of systematic botanists. For example, De Candolle enumerates 389 supposed species, of which at least one half are of artificial origin. While however science has been embarrassed by this facility of crossbreeding, the gardens have been enriched by crowds of the most beautiful objects, in which the features of their savage progenitors can no longer be recognised; and it is probable that of all the flowers which have been acted upon by the hand of man, the Pelargonium is that in which the result has been most striking.

By care and attention to a few simple points of practice, these plants may be cultivated and multiplied by any one who has a greenhouse, and hence they have become universal favourites. These points are the following, namely: 1, water, 2, warmth, 3, a gentle bottom heat, 4, abundance of air, 5, as much light as the leaves will bear, and 6, a rich soil during the season of growth; and a cool atmosphere, less water, abundance of light, and close pruning afterwards.

PELASGI (Πελασγοί) were the most antient inhabitants of Greece, as far as the knowledge of the Greeks themselves extended. A dynasty of Pelasgic chiefs existed in Greece before any other dynasty is mentioned in Greek traditions. Danaus is in the ninth, Deucalion in the eighth, and Cadmus in the seventh generation before the Trojan war; but Phoroneus the Pelasgian is in the eighteenth generation before that epoch. The Greek traditions represent the Pelasgic race as spread most widely over almost all parts of Greece and the islands of the Grecian archipelago. The whole of Hellas, according to Herodotus (ii. 56), was originally called Pelasgia; and Æschylus (*Suppl.*, 250) introduces Pelasgus, king of Argos, as claiming for the people named after him all the country through which the Algos flows, and to the west of the Strymon. We find mention of the Pelasgi in the Peloponnesus, Thrace, Thesprotia, Attica, Bœotia, and Phocis. (Strabo, vii. 321; Herod., viii. 44.) The oracles of Delphi and Dodona were originally Pelasgic (Strabo, ix. 402; vii. 327; compare Herod., ii. 52); and Mr. Clinton (*Fast. Hell.*, vol. i., p. 98) and Niebuhr (*Rom. Hist.*, vol. i., p. 27) have adduced reasons for believing that the Macedonians also were a Pelasgic race. We also find traces of the Pelasgi in many of the islands of the Ægean Sea, as Lemnos, Imbros, Lesbos, Chios, &c. (Strabo, xiii. 621), and Herodotus informs us (vii. 95) that the islands were inhabited by the Pelasgic race till they were subdued by the Ionians. The neighbouring coast of Asia Minor was also inhabited in many parts by the Pelasgi. (Strabo, xiii. 621.) The country afterwards called Æolis was occupied by Pelasgians (Herod., vii. 95); and hence Antandros was called Pelasgic in the time of Herodotus (vii. 42). Tralles in Caria was a Pelasgic town (Niebuhr, *Rom. Hist.*, vol. i., p. 33), and two of their towns on the Hellespont were still extant in the time of Herodotus (i. 57).

The preceding authorities are sufficient to show the wide diffusion of the Pelasgic race; but it is a difficult matter to determine from what quarter they originally came. Many modern writers (Malden, *Hist. of Rome*, p. 69; Bishop Marsh, *Horæ Pelasgicæ*, c. i) conclude, from our knowledge of the original seats of the human race, that the Pelasgians spread themselves from Asia into Europe, across the Hellespont, and round the northern shores of the Ægean Sea. But this opinion, though it may be true, is opposed to many Greek traditions, which represent the Peloponnesus as the original seat of the Pelasgians, whence they spread to Thessaly, and thence to the islands of the Grecian archipelago and to the Asiatic coast.

Phoroneus, son of Inachus, king of Argos, is represented by most Greek traditions as the first king of the Pelasgi, and the early chronologers give a list of his successors at Argos. One of these kings, Pelasgus, who was in the ninth or tenth generation from Phoroneus, is said to have colonised Arcadia; but according to the Arcadian traditions, the Pelasgi originated in Arcadia. (Paus., viii. 1, § 2; Ephorus, *apud Strab.*, v. 221.) From the Argive Pelasgians the race spread to Asia and the other parts of Greece, but it is difficult to arrange the times of these early Pelasgic migrations. Clinton (*Fast. Hell.*, vol. i., p. 14) places them in the following order:—1, A migration under a Pelasgic chief, represented by Xanthus, son of Triopas, planted a colony first in Lycia and afterwards in Lesbos. (Diod., v. 81.) 2, Two generations later a migration proceeded to Thessaly, represented by Achæus, Phthius, and Pelasgus, sons of Larissa.* 3, Nearly contemporary with this migration, and in the ninth generation from Phoroneus, a Pelasgic chief, probably derived from Argos, established himself in Arcadia. 4, Two generations afterwards, the Œnotrians and Peucetians, Pelasgic tribes, described under the persons of Œnotrus and Peucetius, sons of Lycaon, migrated to Italy. (Dionys., *Antiq.*, i., p. [illegible].)

The Pelasgians were widely spread over the south of Italy; and the places in which they appear to have been settled are indicated by Mr. Malden (*Rom. Hist.*, p. 72-83) and Niebuhr (*Rom. Hist.*, vol. i., p. 22-63). There seems no reason for rejecting, as some modern writers have done, the account of Dionysius, that the Pelasgi emigrated from Greece to Italy.

In some parts of Greece the Pelasgians remained in possession of the country to the latest times. The Arcadians were always considered by the Greeks themselves as pure

---

* Wordsworth's Ecc. Biog., v. [illegible]

* The name Larissa frequently occurs in Pelasgic localities. It was also a common name of the citadel or akropolis of the Pelasgians; thus we find that the citadel of Argos was called Larissa (Paus., ii. 24, § 1), and we also read of two Larissas in Thessaly, a Larissa near Troy, another near Cumæ, another in the territory of Ephesus, another near Tralles, on the borders of the plain of Cayster, as well as many others. ([illegible])

Pelasgians, and a Pelasgian dynasty reigned in Arcadia till the second Messenian war. (Herod., i. 146: ii. 171; viii. 73.) According to Herodotus (viii. 44; i. 57), the Athenians were a Pelasgic race, which had settled in Attica from the earliest times, and had undergone no change except by receiving a new name and adopting a new language. In most parts of Greece however the Pelasgic race became intermixed with the Hellenic, but the Pelasgi probably at all times formed the principal portion of the population of Greece. The Hellenes excelled the Pelasgi in military prowess and a spirit of enterprise, and were thus enabled in some cases to expel the Pelasgi from the country, though the Hellenes generally settled among the Pelasgi as a conquering people.

The connection between the Pelasgic and Hellenic races has been a subject of much controversy among modern writers. Many critics have maintained that they belonged to entirely different races, and some have been disposed to attribute to the Pelasgians an Etruscan or Phœnician origin. It is true that many of the Greek writers speak of the Pelasgians and their language as barbarous, that is, not Hellenic; and Herodotus (i. 57) informs us that the Pelasgian language was spoken in his time at Placia and Scylace on the Hellespont. This language he describes as barbarous; and on this fact he mainly grounds his general argument as to the antient Pelasgian tongue. It may however be remarked, that it appears exceedingly improbable, if the Pelasgic and Hellenic languages had none or a very slight relation to each other, that the two languages should have so readily amalgamated in all parts of Greece, and still more strange that the Athenians and Arcadians, who are admitted to have been of pure Pelasgic origin, should have lost their original language, and learned the pure Hellenic tongue. In addition to which it may be added, that we scarcely ever read of any nation entirely losing its own language and adopting that of its conquerors. Though the Persians have adopted many new words into their language from their Arab masters, yet twelve centuries of Arab domination have not been sufficient to change in any essential particular the grammatical forms and general structure of the antient Persian; and notwithstanding all the efforts that were used by our Norman conquerors to bring the French language into general use in this country, the Saxon remains to the present day the main element of our language. It is therefore reasonable to suppose that the Pelasgic and Hellenic tongues were different dialects of a common language, which formed by their union the Greek language of later times.

The antient writers differ as much respecting the degree of civilization which the Pelasgi attained before they became an Hellenic people, as they do respecting their original language. According to some antient writers they were little better than a race of savages till conquered and civilised by the Hellenes; but others represent them, and perhaps more correctly, as having attained a considerable degree of civilization previous to the Hellenic conquest. Many traditions represent the Pelasgians as cultivating agriculture and the useful arts; and a modern writer (Thirlwall's *Greece*, vol. i., p. 59) rather fancifully supposes that the most antient form of their name (Πελαργοί) signified inhabitants or cultivators of the plain. It is a curious fact, which has been noticed by Mr. Malden, in his 'History of Rome' (p. 70), that the Grecian race which made the most early and most rapid progress in civilization and intellectual attainments, was one in which the Pelasgian blood was least adulterated by foreign mixture—the Ionians of Attica and of the settlements in Asia; and that we probably owe to the Pelasgic element in the population of Greece all that distinguishes the Greeks in the history of the human mind. The Dorians, who were the most strictly Hellenic, long disdained to apply themselves to literature or the fine arts.

Some writers have maintained that the Greeks derived the art of writing and most of their religious rites from the Pelasgians; but without entering into these questions, it may be asserted with some degree of certainty that the most antient architectural monuments in Europe clearly appear to have been the works of their hands. The structures in Greece, Italy, and the western coast of Asia Minor, usually called Cyclopean, because, according to the Greek legends, the Cyclopes built the walls of Tiryns and Mycenæ, may properly be assigned to a Pelasgian origin. All these structures are characterised by the immense size of the stones with which they are built; the most extraordinary of all is the treasury or tomb of Atreus at Mycenæ, of w an account is given under MYCENÆ.

(Marsh's *Horæ Pelasgicæ*; Niebuhr's *Hist. of R* vol. i, p. 25-62; Malden's *Hist. of Rome*, p. 69-83; T wall's *Hist. of Greece*, vol. i., p. 32-62; Clinton's *Fasti H lenici*, vol. i., p. 1-30; Wachsmuth's *Hellenische Altert kunde*, vol. i., part i., s. 9; Curtius, *De Antiquis Italiæ I colis*, s. 6, 7; Kruse's *Hellas*, vol. i., p. 404, &c.)

PELASGIAN ARCHITECTURE. [PELASGI.]

PELA'YO, first king of Asturias, was the son of F duke of Cantabria, and a descendant of Chindaswind twenty-eighth in order among the Gothic kings of S After the disastrous battle of Guadalete (A.D. 711), all Christians who either feared the cruelties of the M conquerors or could not bear their yoke, fled for re the inaccessible mountains of the Asturias, where the of the invaders had not yet reached. Among them Pelayo, who, according to some authorities, had fou bravely on the plains of Xerez, and witnessed the de the Christian arms, but who, if we follow the accou the Arabian writers, escaped from Cordova, where he retained as a hostage for the fidelity of his countrymen. his arrival among the refugees, Pelayo was appointed chief. At first these relics of the Gothic monarchy only to have been animated by the wish of self-pr tion, but on their numbers increasing, they thought viving the expiring embers of liberty. Al-horr Ibn A rahman, who governed Spain in the khalif's name [M having been apprised of their intentions, despatched a siderable force under Alkama, to crush the rising in tion, but the followers of Pelayo had already gained p sion of the mountain pass of Auseva, near the river S and concealed part of their force in the cavern of C donga. While the Moslems were ascending the acclivity where the Christians were encamped, and wher chapel of St. Mary now stands, a sudden attack up of their flanks, accompanied by a shower of stones, and f ments of rocks hurled down from the top of the moun threw their ranks into confusion. Pelayo and his fo then issued from the cavern, and the Moslems fled cipitately from the field of battle, leaving their gener thousands of their men (A.D. 718).

Pelayo's success did not end here. Munuza, or A nayzir, the governor, some say, of Leon, others, of G who hastened to the assistance of his countrymen, l life in a like manner, and his army was completely de These memorable events fixed the destiny of the n kingdom. The important city of Leon, long the c Pelayo's successors, was next reduced (722), as well as Z mora, Lugo, and Astorga, and although the Mohamm in 724 recovered some of these places, the intestine wa which they themselves were engaged, and the repeated cursions of Pelayo, helped to consolidate the little king which the Asturian hero transmitted to his succe Alonso el Casto. The remainder of Pelayo's reign is known. He died in 737, and was buried in the chur Santa Eulalia at Cangas de Onis. Pelayo is entitled t grateful remembrance of posterity. At the head of a h ful of men he checked the torrent of Mohammedan inva and laid the foundations of a power which, after eig turies of unremitting and bloody warfare, accomplished final expulsion of the Mohammedan invader from peninsula.

(Mariana, *Historia General de España*, lib. vii., c Masdeu, *Historia Critica*, vol. xii.; Conde, *Historia Dominacion de los Arabes en España*, vol. i. p. 73; F bon, *Cartas para ilustrar la Historia de España*, M 1806.)

PELECA'NIDÆ, Dr. Leach's name for a fam *Natatores*, or Swimming Birds.

The genus *Pelecanus* of Linnæus, placed in the 'Sy Naturæ' between *Diomedea* and *Plotus*, contains the Pelicans (*Pelecanus Onocrotalus*), the Frigate B Man-of-War Bird (*Tachypetes*), under the designa *P. Aquilus*, the Cormorants (*Pelecani Carbo* and *Gr* and the Solan Goose and Boobies.

The *Totipalmes* of Cuvier (comprising those *Palm* which have the hind toe united with the others in a membrane, perch on trees, are good fliers, and have legs) consist of the *Pelicans* (*Pelecanus*, Linn., c hending all those which have the base of the bill of feathers. Their nostrils are slits, the aperture of w scarcely perceptible. The skin of the throat is more or less extensible, and their tongue very small. Their stomach or gizzard, if gizzard it may be called, forms one large sac with their other stomachs. Their eyes are only moderate or small. The following are the genera comprehended under the *Pelecanidæ*: the Pelicans properly so called (*Onocrotalus* of Brisson, *Pelecanus* of Illiger); the Cormorants (*Phalacrocorax* of Brisson, *Carbo* of Meyer, *Halieus* of Illiger); the Frigates (*Pelecanus Aquilus*, Linn., *Tachypetes*, Vieill.); the Boobies (*Sula* of Brisson, *Dysporus* of Illiger). The Pelicans are succeeded by the Anhingas (*Plotus*, Linn.), and the Tropic Bird (*Phaeton*, Linn.).

Mr. Vigors, in his 'Observations on the Natural Affinities that connect the Orders and Families of Birds' (*Linn. Trans.* vol. xiv.), observes that the *Pelecanidæ* are distinguished by a syndactyle foot, the hind toe being directed to the front, and all the toes being united in a membrane. The *Alcadæ* have no hind toe; but these two families are, in the opinion of Mr. Vigors, brought into contact by *Aptenodytes* (Penguins), which possesses a hind toe, small and feeble in construction, in which it approaches the preceding *Alcadæ*, while on the other hand, it has this member directed to the front, but without a connecting membrane, by which means the four toes are similarly placed with those of the *Pelecanidæ*, which, according to the system of Mr. Vigors, comprise the whole of the groups which formed the genera *Pelecanus*, *Phaeton*, and *Plotus* of Linnæus. 'The first of these genera,' continues Mr. Vigors, 'is divided into the following generic groups:—*Phalacrocorax*, Briss., which seems to retain the nearest affinity to the birds of the last family in habits and appearance; *Onocrotalus*, Briss., the genus so familiar to us as including the *Pelican of the Wilderness*; *Sula*, Briss., which contains our Gannet; and *Tachypetes* of M. Vieillot, the *Frigate bird* of our navigators. The manners of this last bird I have discussed somewhat at large at the commencement of this inquiry, as well as the various particulars by which it deviates from the type of the *Natatores*, in conjunction with the greater portion of the present family. I shall not therefore dwell upon the subject any further than to mention its intimate and acknowledged connection with the genus *Phaeton*, both in habits and general economy. In these particulars, as well as in the length of their wings and their extended powers of flight, these two groups evince a near alliance with the family of *Laridæ*, which succeeds, and from which they can only be separated in consequence of their syndactyle feet. The genus *Plotus*, united by its bill to *Phaeton*, leads back to the earlier groups of the *Pelecanidæ*, with which though it differs from them by the straightness of the bill, it agrees in manners and general appearance.'—and he goes on to observe that *Phaeton* bears a considerable resemblance in general appearance and habits to *Sterna* among the *Laridæ*, which family he next enters.

Mr. Swainson, who places the *Pelecanidæ* between the *Mergidæ* and the *Laridæ*, describes the Pelicans as flying with ease and even with swiftness, and as a large, voracious, and wandering tribe, living for the most part at the ocean, and seldom approaching land but at the season of incubation. Their bill is long, and armed at the end with an abrupt hook, the width of the gape excessive; the face generally bare of feathers, and the skin of the throat sometimes so extensible as to hang down like a bag; by this singular organisation, observes Mr. Swainson, the pelicans are able to swallow fish of a very large size, and the whole family may be termed marine vultures. In this part of the work (*Classification of Birds*) the genera comprised under the *Pelecaninæ* are, *Pelecanus*, *Carbo*, *Dysporus*, *Phaeton*, and *Plotus*. In the 'Synopsis' *Phaeton* is arranged as a subgenus of Terns (*Sterna*), in the family *Laridæ*. [Tropic Bird.]

Mr. George Robert Gray, of the British Museum, in his 'List of the Genera of Birds, with an Indication of the Typical Species of each Genus' (London, 1840*), makes the *Pelecanidæ* the sixth and last family of the *Natatores*, and separates it into the subfamilies *Plotinæ*, *Phaetoninæ*, and *Pelecaninæ*. The last subfamily consists of the genera *Sula*, *Onocrotalus*, *Pelecanus*, *Phalacrocorax*, and *Graculus*.

Pelecanus. (Linn.)

Generic Character.—Bill long, straight, wide, very much depressed; upper mandible flattened, terminated by a very strong hook or nail, which is compressed and very much bent; lower mandible formed by two osseous branches, which are depressed, flexible, and united at the point, and from which a naked skin in the form of a bag is suspended. Face and throat naked. *Nostrils* basal, in the shape of longitudinal slits. *Feet* strong and short; three anterior toes; the hind toe is articulated anteriorly, but on the same plane with the others, and all are united by a membrane; middle claw without dentilations. *Wings* moderate; first quill shorter than the second, which is the longest; greater wing-coverts and secondaries nearest to the body as long as the quills. (*Temm.*)

Head of Pelican.

Foot of Pelican.

The true Pelicans are large and heavy birds, with a great extent of wing, and are excellent swimmers. The expansive pouch, whose elasticity is well known to all who have witnessed the shapes into which it is stretched and formed by the itinerant showman, will hold a considerable number of fish, and thus enables the bird to dispose of the superfluous quantity which may be taken during fishing expeditions, either for its own consumption or for the nourishment of its young. In feeding the nestlings,—and the male is said to supply the wants of the female when sitting in the same manner,—the under mandible is pressed against the neck and breast, to assist the bird in disgorging the contents of the capacious pouch; and during this action the red nail of the upper mandible would appear to come in contact with the breast, thus laying the foundation, in all probability, for the fable that the Pelican nourishes her young with her blood, and for the attitude in which the imagination of painters has placed the bird in books of emblems, &c., with the blood spirting from the wounds made by the terminating nail of the upper mandible into the gaping mouths of her offspring.*

The neighbourhood of rivers, lakes, and the sea-coasts are the haunts of the Pelicans, and they are rarely seen farther than twenty leagues from the land. They appear to be, to a certain extent, gregarious. Le Vaillant, upon visiting Dassen Eyland, where was the tomb of a Danish captain, at the entrance of Saldanha Bay, beheld, as he says, after wading through the surf and clambering up the rocks, such a spectacle as never perhaps appeared to the eye of mortal. 'All of a sudden there arose from the whole surface of the island an impenetrable cloud, which formed, at the distance of forty feet above our heads, an immense canopy, or rather a sky, composed of birds of every species, and of all colours:—cormorants, sea-gulls, sea-swallows, pelicans, and, I believe, the whole winged tribe of this part of Africa, were here assembled. All their voices, mixed together and modified according to their different kinds, formed such a horrid music that I was every moment obliged to cover my head to give a little relief to my ears. The alarm which we spread was so much the more general among these innumerable legions of birds, as we principally disturbed the females which were then sitting. They had nests, eggs, and young to defend. They were like furious harpies let loose against us, and their cries rendered us almost deaf. They often flew so near us that they flapped their wings in our faces; and though we fired our pieces repeatedly, we were not able to frighten them; it seemed almost impossible to disperse this cloud. We could not move one step without crushing either their eggs or their young ones; the earth was entirely strewed with them.' The same traveller found on the Klein-Brak river, whilst waiting for the ebb tide, thousands of pelicans and flamingoes, the deep rose-colour of the one strongly contrasting with the white of the other.

---

* A second edition appeared.

* [illegible]

Geographical Distribution.—The species are widely spread (Europe, Asia, Africa, and America), though not numerous: two are Europeans, *Pelecanus Onocrotalus*, and *Pelecanus crispus*. We select the former as an example.

Description. (*Old.*)—The plumage generally of a fine white tinted with light rose or salmon colour, which is brightest in the breeding season, except the primaries and spurious wing, which are black, and the depending occipital crest and a few pendulous feathers on the lower part of the neck, which are light yellow; naked space round the eyes and at the base of the bill, where the frontal feathers form a point, flesh-colour; the upper mandible bluish, with a crimson line running along the top, reddish at the base, yellowish at the tip, and the terminal nail red; guttural pouch yellow; irides bright reddish brown or hazel; feet livid; tail short. Length from five to six feet; expanse of wings twelve or thirteen feet. Sexes similar.

Young of the year, and those of a year old.—Whitish ash throughout; belly whitish; wings and back very deep ash; all the feathers bordered with brighter ash; quills blackish ash; bill and naked parts livid; iris brown. The first white feathers appear on the neck and belly. (Temm.) Mr. Gould (*Birds of Europe*) says that the bird is remarkable for longevity, and for the long period requisite for the completion of its plumage. The first year's dress he describes as wholly brown, the feathers of the back and breast being broad and rounded. The lanceolate feathers and the rosy tints are only acquired as the bird advances in age, and Mr. Gould thinks, judging from individuals in partial confinement, that five years are required before the bird becomes fully mature.

Food, Habits, Reproduction, &c.—Fish is the food of the Pelican, which it captures with great adroitness, generally in shallow inlets. It is no diver, but it will occasionally dash from a great height on the wing upon a fish with such velocity that it becomes submerged, though its buoyancy brings it instantly to the surface again. Although it perches on trees, it seems to prefer rocky shores. The nest, generally formed of coarse reedy grass, with a lining of grass of a softer quality, is large (about a foot and a half in diameter), and made upon the ground. Two, three, four, and sometimes five pure white eggs, but mostly two, of nearly the same size at both ends, are laid in it.

Sonnerat found five under a female of this genus. She would not rise to let him pass, but kept her seat. She struck at him with her bill, and screamed when he attempted to drive her from her eggs. Labat fastened two young pelicans to a stake. The mother daily brought them food, and remained with her young ones constantly until the evening, when she flew up to roost in a tree immediately above them. The trio became very familiar, suffering Labat to touch them; and the young ones gratefully accepted the little fish which he offered to them, and which they first put into their pouches. These Pelicans were, in all probability, not of the species under consideration.

Localities.—The Oriental countries of Europe; common on the rivers and lakes of Hungary and Russia; tolerably abundant on the Danube; rare and accidental on the sea-coast. An adult specimen, sent to M. Temminck, who the above habitats, from Egypt, and another from the Cape of Good Hope, differed in nothing from those of Europe, except in their greater dimensions. That the species exists in Asia there is no doubt. Belon, who refers to *Leviticus* (xi. 18), where the bird is noted as unclean, says that it is frequent on the lakes of Egypt and Judæa. When he was passing the plain of Roma, which is only half a day's journey from Jerusalem, he saw them flying in pairs like swans above his head, rather low; and adds that they are seen flying in a large flock like those birds. Hasselquist saw it at Damietta in Egypt. He also adds that it comes to Egypt in the middle of September, in his chapter on the arrival there of migrating birds. 'In flying,' says Hasselquist, 'they form an acute angle, like the common wild geese when they migrate. In the summer they inhabit the Black Sea and coasts of Greece; and in their migration remain for a few days near Smyrna and other parts of the coasts of Natolia, but never stray far from the continent: they fly very high. Some of them remain at Damietta, and in the islands of the delta in the Mediterranean, but the greater part go to Egypt.' They appear in some of the Egyptian drawings. (Rossellini.)

Dr. Von Siebold and M. Bürger saw it in Japan, and their observation is confirmed by M. Temminck. Mr Gould states that though the tropical climates of Africa and India constitute its natural habitat, nevertheless the eastern rivers of Europe, such as the Danube and Volga, the extensive lakes of Hungary and Russia, and the shores of the Mediterranean, are places where it dwells in abundance. The same author says that it is a species strictly confined to the Old World, over a great part of which it is distributed. The Prince of Musignano, in *Specchio Comparativo*, quotes it as being rare and adventitious at Philadelphia and Rome. Dr. Richardson quotes it, or rather a variety of it, killed on the Missinippi, 56° N. lat. 'Pelicans,' says the Doctor, 'are numerous in the interior of the fur countries up to the sixty-first parallel; but they seldom come within two hundred miles of Hudson's Bay. They deposit their eggs usually on small rocky islands, on the brink of cascades, where they can scarcely be approached; but they are otherwise by no means shy birds. They fly low and heavily, usually in flocks from six to fourteen, sometimes abreast, at other times in an oblique line; and they often pass close over a building or within a few yards of a party of men without exhibiting any signs of fear. They haunt eddies under waterfalls, and devour great quantities of carp and other fish. When gorged with food, they doze on the water, and may be easily captured, as they have great difficulty in taking wing at such times, particularly if their pouches be loaded with fish. Though they can perch on trees, they are most generally seen either on the wing or swimming. Some specimens, apparently in mature plumage, have the bill quite smooth above; but individuals have a long thin bony process, about two inches high, springing from the ridge of the upper mandible. Similar processes existed in the specimens commented upon by Pennant and Forster, which were brought from Hudson's Bay: but no such appearances have been described as occurring on the bills of the White

Pelecanus Onocrotalus.

Pelicans of the Old Continent.' The Prince above quoted, in his later *Geographical and Comparative List*, erases *Pel. Onocrotalus* from the column of American birds, supplying its place by *Pelecanus Trachyrhynchus*, Lath. (*Pel. erythrorhynchos*, Gm., *Pel. Americanus*, Aud.), and this probably is the species alluded to by Dr. Richardson: indeed there can be little or no doubt of it.

The following notes, by Professor Owen, throw much light on the organization of birds of this group as applicable to their habits.

The Pelican which he dissected—*Red-backed Pelican* of Latham, *Pelecanus rufescens*, Gmel., a female—measured three feet seven inches from the extremity of the beak to the anus, and ten inches and a half from the extremity of the upper mandible to the nostrils. 'These,' says the Professor, 'are almost concealed slits in the lateral grooves of the upper mandible, just anterior to the skin of the head. They will barely admit the flat end of a probe; and lead almost vertically to the internal apertures of the nasal cavity. The air-cells in the *Pelican*, as in the nearly allied bird the *Gannet*, *Sula Bassana*, Temm., are remarkably extended and diffused over the body: the whole cellular tissue, even to the tips of the wings and the end of the fleshy part of the legs, can be blown up from the *trachea*.

'The extent to which the skeleton of the *Pelican* is permeated by air has been particularly noted by Mr. Hunter in his celebrated paper 'On the Air-cells of Birds,' in which he throws out a suggestion that it may assist the birds of this species in carrying heavy loads in their large *fauces*. This supposed relation of extended air-cells to a largely developed beak is borne out in the case of the *Hornbill*, in which every bone of the skeleton is permeated by air, but is apparently contradicted by the *Gannet*; I say apparently, because although the *rami* of the lower jaw do not, in this species, afford suspension to a capacious reservoir, as in the *Pelican*, yet the bird may occasionally have to bear away a considerable load, as, for instance, in a large fish seized by its mandibles, and a previous accumulation in its dilatable *œsophagus*.

'Mr. Hunter, it may be remembered, was doubtful, on the first publication of his paper, as to the source from which the mandibles derived their gaseous contents; not that he was ignorant of the air-holes in the bones, as he is careful to tell us in the reprint of the Memoir, in the "Animal Œconomy," where he states that the lower jaw of the "*Pelican* is furnished with air, which is supplied by means of the Eustachian tube."

'To ascertain the correctness of this description, I sawed across the left *ramus* of the lower jaw; but on blowing into the end of the part attached to the head, I found that the air did not escape, as I had expected, by the Eustachian tube (the orifice of which is a slit, situated on the roof of the mouth, one inch behind the posterior or internal *nares*), but filled, first the air-cells under the throat, and then, passing down the neck, raised the large air-cell above the *furculum*. On dissection, I found that the air passed into the lower mandible immediately from an air-cell surrounding the articulation between the jaw and *os quadratum*, which received its air from the lungs by means of the cells passing along the neck and throat, &c. The authority of Mr. Hunter ought not to be set aside by the result of a single experiment; and the possibility of accidental rupture may be urged against the above observation; but it is at all events worthy of being recorded, and should be repeated when opportunity occurs, with the addition of blowing into the Eustachian tube, which I omitted to do.

'There is little to be added to the accounts already given in the works of Cuvier, and of Professor Tiedemann and Carus, of the digestive organs of the *Pelican*. The weak or thin-coated stomach, small cæca, and short intestines bespeak its animal diet; and the uniformly capacious œsophagus, as well as the suspended faucial bag, may be regarded as pointing to the piscivorous habits of this singular species. It is more difficult to assign the use of the globular cavity interposed between the gizzard and the *duodenum*, which the *Pelican* has in common with some of the piscivorous *Grallæ*, viz. those of the genus *Ardea*. In them the pyloric cavity is very small, but in the *Pelican* it is fully as large in proportion as in the *Crocodiles*, which alone possess it among *Reptiles*. In the *Pelican* here described the pyloric cavity measured one inch and a half in diameter, communicated by a small transverse aperture with the gizzard, and by an opposite one, of smaller size and obliquely placed, with the *duodenum*. Its lining membrane is villous and vascular, and was in this instance tinged with bile, which must have entered by regurgitation, as none of the biliary ducts enter here.

'The *œsophagus* is continued into the *proventriculus* without any marked constriction, and the latter passes insensibly into the part analogous to the gizzard, which is comparatively of small size. The gastric glands are simple elongated follicles, closely compacted together, and extended over nearly the whole *proventriculus*.

'The *duodenum*, after making the usual fold, ascends on the right of the stomach; the intestine is then disposed in three or four coils upon a central mesentery, and then is strung on the edge of the mesentery in long and deep folds, from the last of which the *ileum* passes upwards behind the stomach, and then descends to join the *rectum*. At the point of junction were placed the *cæca*, each one inch and a half in length. The *rectum* is very short, and opens obliquely into a large urinary receptacle, as large, proportionately, as in the *Ostrich*. Before commencing the dissection, a quantity of very fluid urine, of a whitish colour, and containing whitish flakes, escaped on pressure being made upon the sides of the *cloaca*.

'The *liver* is bilobed, the right lobe much larger than the left, in which the edges were rounded off. There is a gall-bladder, which contained bile of a yellow colour, not green as in birds generally. The cystic, biliary, and hepatic ducts terminated in the end of the *duodenum*, close to which opened the duct of the *pancreas*. The latter gland was of a less elongated form than usual, being of a rounded figure, and not descending far into the fold of the *duodenum*. The spleen was placed behind the stomach, in length one inch, in breadth half an inch.

'The kidneys were of large size, being four inches long, two deep, and one and a half wide, which is very unusual in birds; the right kidney was half an inch higher than the left. Many of the small superficial branches of the ramified ureter which characterises the kidneys of the oviparous animals, were beautifully conspicuous from their white opake contents. The supra-renal glands were of a light yellow colour, and of a rough or granular pulpy texture; the right adhered closely to the *vena cava*, the left as closely to the ovary, which seemed to be developed partly from the gland and partly from the coats of the left femoral vein. The largest ova were nearly of the size of peppercorns, and about twenty in number: there were innumerable smaller ones. The oviduct was narrow at its commencement, but gradually attained a diameter of about four lines; it passed along the anterior part of the left kidney, adhering thereto by its peritoneal ligament.

'As the *Pelican* belongs to the group of *Natatores*, the *Totipalmes* of Cuvier, which contains species approximating most closely to the *Raptorial Birds*, and which are almost the only birds of this order, as Cuvier observes (*Règne An.*, nouv. éd., i., p. 361), that perch, I did not fail to try the common experiment suggested by Borelli's observations on the effect which bending the leg and ancle-joints might have upon the toes; the latter however exhibited no corresponding inflection. In perfect agreement with this is the observation that the *Pelicans* do not perch when they go to rest.' (*Zool. Proc.*, 1835.)

The dissection of a male of the same species, by Mr. Martin, is given in the same volume.

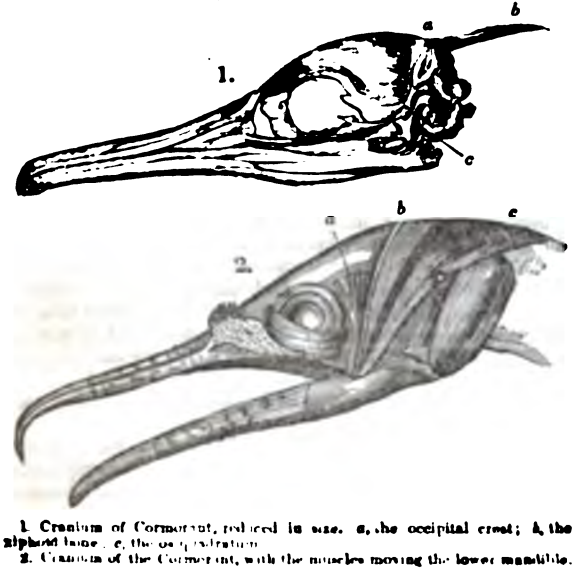
Phalacrocorax. (Briss.)

Generic Character.—*Bill* moderate or long, straight, compressed; upper mandible very much curved towards the point, and hooked; lower mandible compressed; base inserted in a small membrane, which extends under the throat. Sides of the face and throat naked. *Nostrils* basal, linear, hidden. *Feet* strong, short; three toes before, the hind-toe articulated interiorly, all united by a membrane; nail of the middle toe serrated. *Wings* moderate, the first *quill* longer than the second, which is longest.

This is the genus *Halieus* of Illiger, *Carbo* of Meyer, and *Hydrocorax* of Vieillot.

Mr. Yarrell, who observes (*Zool. Journ.*, vol. iv.) that most of those authors who have written on the comparative anatomy of birds agree in describing an additional bone as peculiar to the back part of the head of the Cormorant, or *Corvorant*, as he writes it (*Pelecanus Carbo*), adds that the muscles attached to this bone, and the services they are destined to render the animal, have been either overlooked or misconceived. He describes the additional bone as about one inch in length, triangular in shape, somewhat grooved on its surfaces, and, from its articulation with the occiput, tapering gradually to a point. The mode by which this bone is articulated to the occiput is considered by Mr. Yarrell to be similar to that observed in the ribs of serpents, in which the condyle is situated upon each vertebra, and the cavity is at the end of the rib: so in the Cormorant, the condyle is upon the occipital bone, the cavity at the triangular end of the xiphoid bone; the joint is therefore hemispherical, admitting great extent of motion. Mr. Yarrell then notices the great length of the os quadratum (*c*) from above downwards, in this and other birds which feed on fishes. The articulation of this bone, he observes, both with the cranium itself, as well as with the lower mandible, admits great latitude of motion. It moves with facility backwards, forwards, outwards, and inwards, by the action of the numerous muscles attached to it, thus increasing the capacity of the pharynx for the more easy passage of any unusually large fish. The rami of the lower mandibles are comparatively slender, weak, and elastic, and hence the value of the additional pair of muscles described by Mr. Yarrell, muscles which are not, he states, possessed by any of the species of *Colymbus*, *Alca*, *Uria*, and *Larus*, all of which have the rami of the lower mandibles much deeper and thicker in proportion.

The xiphoid or sword-shaped bone is described by Mr. Yarrell as having three surfaces, each slightly concave, forming together an isosceles triangle, the base of which is downwards. 'From the upper edge of this bone,' says Mr. Yarrell, 'to its lateral angle, throughout its whole length, from the extreme point to the occiput, there arises on each side a triangular-shaped long muscle, the fibres of which are directed forwards, downwards, and outwards, to be inserted by a strong tendon upon the upper edge of the lower mandible, immediately behind the insertion of the tendon of the temporal muscle. The muscles of the upper part of the neck, giving motion to the head, are inserted upon the occipital bone and its elevated crest, over which these additional muscles slide with every movement of the head, the particular articulation of the xiphoid bone only permitting it to become a fixed point of support to its own particular muscles, when both act simultaneously as additional elevators of the lower mandible, thus assisting in prehension, and materially increasing the power of the bird in securing a slippery prey. I may here also observe that the various other species of fish-feeding birds before referred to as having their lower mandibles so much stouter and stronger than the corvorant, have also much deeper *fossæ* and more elevated ridges for the origin and attachment of their temporal muscles, and are in this way better able to prevent the escape of their natural food, without the additional muscles of the corvorant. From these comparative remarks, it will be perceived that the corvorant does not possess the same strength of bone in the mandibles with the other oceanic fish-feeders, though not less inclined than they are to pursue and take fish of large size. The dilatation of which the lower mandible is capable from its elasticity, the length and freedom of motion of the ossa quadrata, the great size of the œsophagus, which, when distended, measures ten inches in circumference, all afford facilities for the swallowing of prey, which, but for his additional muscles, he would probably be unable to hold. This peculiarity of structure is most likely to be found in other species of the genus *Pelecanus*, but it is only in our common Corvorant that I have had opportunities of ascertaining the fact.'



1. Cranium of Cormorant, reduced in size. *a*, the occipital crest; *b*, the xiphoid bone; *c*, the os quadratum.
2. Cranium of the Cormorant, with the muscles moving the lower mandible. *a* and *b*, muscles answering to the masseter and temporal; *c*, the muscle arising from the xiphoid bone. (Yarrell.)

The xiphoid bone exists in the other European species of *Phalacrocorax*, and probably in the whole of that genus, but it is absent in the true Pelicans, and, we believe, in the *Frigate Bird* and *Plotus*. The recorded species are not numerous; five are noted as European. (Gould; Prince of Musignano.) We select two of these as examples.

Phalacrocorax Carbo. (*Old.*)—Under the throat a large white or whitish collar, the upper extremities of which reach to just below the eyes. Summit of the head, neck, breast, all the lower parts and the rump, lustrous greenish black; on the neck small whitish traits, which are nearly imperceptible; feathers of the upper part of the back and wings ashy-brown, or bronzed in the middle, bordered by a broad band of glossy greenish-black; quills and tail feathers black; bill blackish ash; naked region of the eyes greenish-yellow; small guttural pouch yellowish; iris green; feet black. Length 27 to 29 inches (*Both sexes—Winter Plumage*—Temm.).

M. Temminck remarks that individuals in this state of plumage have been most frequently described as females of the species.

Spring or *Nuptial Plumage.*—On the occiput and a part of the nape are long feathers, which form a crest of deep lustrous green; the large collar on the throat is pure white; on the summit of the head, on a great part of the neck, and on the thighs, appear very long, loose, and silky feathers of a pure white. These plumes are more or less long, according to the age of the individual. Rest of the plumage as in winter. (Temm.)

M. Temminck observes that the loose or decomposed plumes, as well as the long occipital feathers, appear in the spring in the interstices of the other feathers of the body, which the second moult does not effect: both sexes are ornamented with the loose plumes, and these accessory feathers fall the first, even before the time of the autumnal moult, so that these Cormorants are never found in this livery except at the season of love and during that of incubation. M. Temminck observes that Cuvier does not appear to have paid attention to this note, inasmuch as he has indicated the crest and the white on the neck as characteristic of the males.

Young of the Year.—Summit of the head, nape, and back, deep brown, with slight green reflections; the large collar whitish-grey; front of the neck and all the lower parts grey-brown, varied with whitish, particularly on the breast and the middle of the belly, where these spots are numerous; feathers of the upper part of the back, scapulars, and coverts of the wings, grey-ash in the middle, bordered by a band of deep brown; bill bright brown; iris brown. It is not till the age of one year that the young assume the perfect winter livery.

M. Temminck, in the 4th part of his *Manuel* [illegible] notices a variety which haunts maritime coasts, observed by MM. Hardy and Cantraine. The bill is larger, being from 12 to 13 lines in thickness, and the total length of the bird reaches 35 inches: the young have more white on the lower parts. The first of these naturalists observed these birds on the coasts of France, and the other on those of the islands of the Mediterranean Sea. This slight difference of stature may be attributed, as M. Hardy thinks (and M. Temminck concurs with him), to the abundance and quality of their food, sea-fish containing more substantial nourishment than river-fish, of which the species [illegible] makes prey.

The Cormorants on the south coasts of England are very large. Pennant relates that he weighed a bird of the species that exceeded seven pounds; the length was three feet four inches; the extent four feet two.

There is little or no doubt that this is the κόραξ [illegible] of Aristotle (*Hist. Anim.*, viii. 3), whose description of the bird and of its habits agrees well with that now [illegible]. It is the *Corvo Marino*, *Corvo Aquatico*, *Marang*[illegible] *rangone*, and *Mergone* of the Italians; *Cormorans* (Le[illegible] and *Cromorant* of the French; *Scharbe* and *See-Rabe* of the Germans; *Skarv* and *Aalekrage* of the Norwegians; *Aalekrage* of the Danes; *Skarfur* of the Icelanders; *Morfran* and *Morvran* of the ancient British; *Corvorant* and *Cormorant* of the modern British. It is the *Corvus Aquaticus* of Gesner, Ray, and others; *Pelecanus Carbo* of Linnæus; *Phalacrocorax Carbo* of Cuvier and others; and *Carbo Cormoranus* of Meyer and others.

It has been a question how the English name of the bird should be spelled, some preferring the form *Corvorant*, which is the form used by Montagu, Latham, Pennant, and Dr. Evans, the last of whom derives the word from *Corvus vorans*. *Cormorant* is considered a corruption by those who adopt this derivation. Milton, Ray, and Willughby write *Cormorant*, which is the form now generally used by British ornithologists.

Geographical Distribution very extensive. The species is an inhabitant of the New as well as the Old Continent. In the latter it is widely diffused. It is spread over a considerable portion of Europe, especially the north. Temminck notices it as very abundant in Holland in all seasons, as common in England and France, but rare in Germany and the south. It appears in the 'Geographical List' of the Birds of Musignano as an inhabitant of Europe generally and of America. In the 'Specchio Comparativo' it is noted as not very rare in winter at Rome, but rare in winter at Philadelphia. In the lately published part (4th) of his 'Manuel,' M. Temminck notes it as common in Sardinia, adding, that though the Japanese species differs but very little from that of our climates, it is nevertheless distinct; but he states that he has received a specimen from India resembling our species in every respect. It is, he says, common in some parts of the Ganges, but is not seen in the islands of Sunda.

Habits, Food, Reproduction, &c.—The Cormorant swims very low in the water; even in the sea the body is deeply immersed, little more than the neck and head being visible above the surface. It is a most expert diver, pursuing the fish which form its food with great activity under water. It is said to be very fond of eels. It flies with the neck outstretched, and may be often seen drying its drenched plumage on the shore or on insulated rocks. It perches on trees, where it is occasionally known to build its nest, but it usually selects rocky shores and islands, selecting, according to Selby, the summits, and not (like the Green Cormorant) the clefts or ledges. The author last quoted states that upon the Fern Islands its nest is composed entirely of a mass of sea-weed, frequently heaped up to the height of two feet, in which are deposited from three to five eggs of a pale bluish-white, with a rough surface. 'The young,' continues Mr. Selby, 'when first hatched, are quite naked and very ugly, the skin being of a purplish-black; this in six or seven days becomes clothed with a thick black down, but the feathered plumage is not perfected in less than five or six weeks. . . . I have repeatedly found that, upon being thrown into the sea, even when scarcely half fledged, they immediately plunge beneath the surface, and endeavour to escape by diving. This they will do to a great distance, using their imperfect wings, and pursuing their submarine flight in the same manner and almost with as much effect as their parents.'

The old French quatrain in the 'Portraits d'Oyseaux' gives no bad account of the habits of this bird:—

'Le Cormorant est oyseau fort commun,
Il [illegible]
[illegible]
[illegible]'

Its voracity is indeed great, and the way in which it will dispose of a large fish, a plaice for instance, aided in a great measure by the powers of compression and dilatation exercised on it by the apparatus noticed above, is surprising. The species is easily domesticated. Montagu, who kept one, gives a favourable account of its disposition, and indeed their docility is shown by the use made of them formerly in fishing. Willughby, quoting Faber, says: "They are wont in England to train up Cormorants to fishing. When they carry them out of the room where they are kept to the fish-ponds, they hoodwink them, that they be not frightened by the way. When they are come to the rivers, they take off their hoods, and having tied a leather thong round the lower part of their necks, that they may not swallow down the fish they catch, they throw them into the river. They presently dive under water, and there for a long time, with wonderful swiftness, pursue the fish, and when they have caught them, they arise presently to the top of the water, and pressing the fish lightly with their bills, they swallow them, till each bird hath after this manner devoured five or six fishes. Then their keepers call them to the fist, to which they readily fly, and little by little, one after another, vomit up all their fish a little bruised with the nip they gave them with their bills. When they have done fishing, setting the birds on some high place, they loose the string from their necks, leaving the passage to the stomach free and open, and for their reward they throw them part of the prey they have caught, to each perchance one or two fishes, which they by the way, as they are falling in the air, will catch most dexterously in their mouths. The kind of fishing with cormorants is, it seems, also used in the kingdom of China, as Nieremberg out of Mendoza relates.' Pennant cites Whitelock, who says that he had a cast of them manned like hawks, and which would come to hand. 'He took much pleasure in them, and relates that the best he had was one presented him by Mr. Wood, master of the corvorants to Charles I.' It is well known, adds Pennant, that the Chinese make great use of a congenerous sort in fishing, and that not for amusement but profit.

Sir George Staunton (*Embassy to China*) states that the embassy, in its journey to Han-chou-fou, 'had not proceeded far on the southern branch of the canal, when they arrived in the vicinity of the place where the *Leu-tze*, or famed fishing-bird of China (*Phalacrocorax Sinensis*), is bred, and instructed in the art and practice of supplying his owner with fish in great abundance. It is a species of the pelican, resembling the common corvorant, but which, on a specimen being submitted to Dr. Shaw, he has distinguished in the following terms:—"Brown pelican or corvorant with white throat, the body whitish beneath and spotted with brown; the tail rounded; the irides blue; the bill yellow." The bird, an undoubted cormorant, is figured in the Atlas, pl. 37, and a vignette at the end of the chapter shows two Chinese fishermen carrying their light boat, around the gunnel of which their cormorants are perched, by a pole, resting on their shoulders, between them. Sir George further says: "On a large lake close to this part of the canal, and to the eastward of it, are thousands of small boats and rafts, built entirely for this species of fishery. On each boat or raft are ten or a dozen birds, which, at a signal from the owner, plunge into the water; and it is astonishing to see the enormous size of fish with which they return grasped between their bills. They appeared to be so well trained that it did not require either ring or cord about their throats to prevent them from swallowing any portion of their prey, except what the master was pleased to return to them for encouragement and food. The boat used by these fishermen is of a remarkably light make, and is often carried to the lake, together with the fishing birds, by the men who are there to be supported by it."'

Phalacrocorax Carbo. Adult male in spring plumage. (Gould.)

Belon gives an amusing account, in his quaint French, of the chase of this bird during calms, especially in the neighbourhood of Venice, the hunt being carried on in very light boats, 'deux ou trois douzaines de compagnie,' each of which, says he, being rowed by five or six men, darts along the sea like the bolt from an 'arbalaste,' till the poor cormorant, who is shot at with bows as soon as he puts his head above water, and cannot take flight, after diving to suffocation, is taken quite tired out by his pursuers.

Phalacrocorax Cristatus (*Old, in Winter dress*).—The whole plumage of the most beautiful resplendent and lustrous green; upper part of the back, scapulars, and wing and tail coverts of a fine bronze; each feather framed as it were by a narrow band of beautiful velvety black; extremity of the wings not reaching beyond the origin of the tail, which is short, rounded, and of a dead black; base of the bill and very small guttural pouch fine yellow; bill brown; feet black; iris green. Length 2 feet 1 or 2 inches.

Old, in the Spring or Nuptial Plumage.—At the commencement of the spring there rises on the middle of the head, between the eyes, a fine tuft of wide and outspread feathers, about an inch and a half high, capable of erection, and which, in that state, present a *toupet*, or large plume; on the occiput also are ten or twelve rather long and subulate feathers. There are never any white feathers on the neck nor on the thighs, as in the Great Cormorant (last-mentioned species).

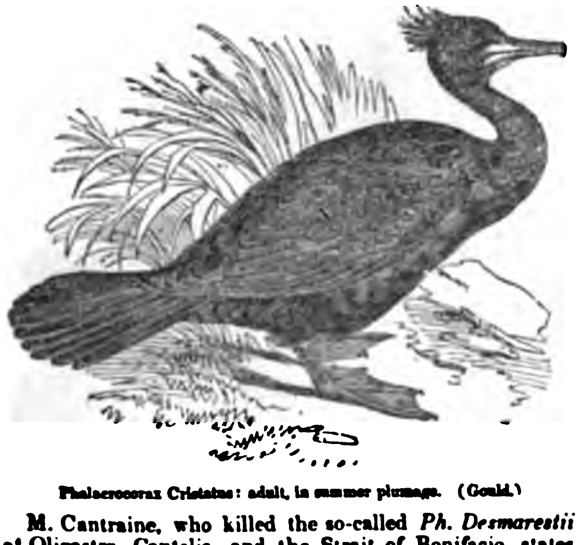
The *Young of the Year* are distinguished from the young of all the other species by their long and slender bill, their short tail, and the wide lustrous borders which surround all the feathers of the mantle. The colour of the upper parts is brown lightly shot with greenish; that of the lower parts is ashy-brown more or less whitish.

The bill of this species is very slender, two inches four lines long, and longer than the head. Tail very short, composed of 12 feathers. (Temm.)

This is the *Cormoran Largup* of Temminck; *Crested Corvorant* of Pennant; Shag or Green Cormorant of Gould.

M. Temminck, in the fourth part of his *Manuel*, states that *Carbo Desmarestii*, Peyrodeau (*Phalacrocorax Desmarestii*, Gould), one of the five European species noticed by Gould (*Birds of Europe*) and the Prince of Musignano (*Geographical List*), which had hitherto appeared to M. Temminck to be a distinct species from the *Cristatus* of the northern seas, is absolutely identical with it. This last opinion is founded on the careful comparison of a number of the so-called *Phalacrocorax Desmarestii* from the south, both adults and in intermediate stages, with individuals from Iceland, the Feroe Islands, the Orcades, and the maritime coasts of the North Sea. M. Temminck remarks that it has been observed that the *Ph. Desmarestii* has the bill longer, but in a great number of *Largups* from Iceland and the Feroe Islands only two were found with the bill of exact length and slenderness.

Habits, Food, Reproduction, &c.—The habits of *Ph. cristatus* are very similar to those of *Ph. Carbo.* The nest is placed in clefts and on ledges of clifts. Mr. Selby found that it was composed of a mass of sea-weed, chiefly *Fucus vesiculosus*, and that the eggs, four or five in number, were smaller than those of *Ph. Carbo*, but similar to them in outward appearance.



Phalacrocorax Cristatus: adult, in summer plumage. (Gould.)

M. Cantraine, who killed the so-called *Ph. Desmarestii* at Oligastra, Cantelia, and the Strait of Bonifacio, states that their principal food consists of the *Sparus Boops*, and that they always keep on rocks near the edge of the water in parties of not more than four; *Ph. Carbo*, which lives in the same localities, perches higher on the rocks.

Localities.—The whole of the north of Europe; very common in Iceland, the Orkneys, Feroe Islands, Norway, and Sweden, in the vicinity of great lakes. M. Boie [illegible] many individuals in lat. 60° (Temm.). To these localities must be added the Mediterranean, if M. Temminck is right, and his opinion does not seem to have been [illegible] formed, in considering *Ph. Desmarestii* and *Ph. cristatus* identical. Indeed Mr. Gould mentions the Mediterranean as a locality of the latter. M. Temminck remarks that [illegible] Japanese species, which in certain points resembles *P. cristatus*, differs, notwithstanding, essentially from it, especially in the extremely slender form of the bill, the [illegible] of the plumage, and the totally different form of the crest.

Plotus. (Linn. Klein.)

Generic Character.—*Bill* longer than the head, [illegible] straight, firm though slender, obliquely dentilated on the edges, which are bent inwards, and terminating in a very sharp point. *Face* and *throat* naked. *Nostrils* [illegible] *Feet* short and robust. *Wings* short; second, third, [illegible] fourth quills longest; tail very long, the feathers stiff and elastic.

This is the genus *Anhinga* of Brisson; *Plottus* of Sco[illegible] and *Ptinx* of Mœhr.

Geographical Distribution of the Genus.—Species of *Plotus*, or *Darter*, as it has been called by English and American ornithologists, are found in the Old and New Continents.

These extraordinary birds are well described by B[illegible] when he says, 'The Anhinga offers us a reptile graft[illegible] the body of a bird.' Those who have seen the long [illegible] and that only, issuing from the water, twisting about [illegible] the herbage and among the foliage, say that a casual observer might well take it for a snake. Vaillant states that the neck of the species seen by him in Africa was always [illegible] oscillation when the bird was perched; and that any one who saw its tortuous movements among the foliage, the body being concealed, would take it for one of the tree serpents. The form indeed was considered by the [illegible] voyagers as a monster partaking of the nature of the [illegible] and the duck; and Wilson states that in some ancient charts which he had seen, the creature was delineated with all the extravagance of fiction. In flight the neck is stretched out, immoveable, in a line with the body.

AFRICAN DARTERS, OR SNAKE-BIRDS.

Plotus Levaillantii.—(*Nuptial Plumage.*)—Bill [illegible] feet yellow; all the upper part of the head and back of head brick-red, bordered with a riband of black [illegible] descends to the shoulders; forehead, cheeks, and sides of the neck pure white; throat and anterior part of the [illegible] pale ochraceous yellow; breast and all the under parts of the body deep black with greenish reflections; the [illegible] part of the neck above the back reddish and ocellated with white; the whole of the mantle and the small [illegible] brown, with the middle of each feather of a bright [illegible] colour; tail-feathers and quills brown, some of the [illegible] terminated with rust-colour.

This is *Plotus Africanus* of Swainson.

Habits.—Le Vaillant in his usual lively style [illegible] how he was induced to visit a rich proprietor in the [illegible] canton of the Twenty-four Rivers to the north east of [illegible] land (South Africa), after he had determined on [illegible] ping, by the tempting description of two extraordinary [illegible] which habitually haunted the vicinity of this proprietor's habitation, and which, from the description, he knew [illegible] be Anhingas. They frequented a particular tree, [illegible] baffled him more than once; at length he got within [illegible] and killed them both, right and left. His Hottentots [illegible] them *Slange-Hals-Voogel* (bird with a serpent's [illegible] He describes them as diving 'entre deux eaux' for [illegible] when they caught a small one it was swallowed whole, [illegible] they captured a large one it was carried to a rock or [illegible] trunk of a tree, and the bird, fixing it beneath its [illegible] picked it to pieces with its bill. Though the water is [illegible] favourite element, it is upon trees or rocks, he tells us, [illegible] it establishes its nest and brings up its young, taking [illegible] to place it so that they may be easily precipitated [illegible] river, as soon as they are able to swim, or whenever [illegible] safety of the little family requires it. He describes [illegible] most difficult of approach, especially when swimming, [illegible] when nothing but the head is to be seen; the instant the flint struck the steel the bird dived, and often when it was looked for a-head, it had doubled back in its diving, and then took wing far behind the sportsman.

Localities.—Senegal, Cape of Good Hope; part of the coasts of Asia (Lesson).

Plotus Levaillantii.

AMERICAN DARTERS.

Example, Plotus Anhinga—Plotus Americanus (Sw.).

Description.—*Male.*—*Bill* 3½ inches long, rather slender, very sharp pointed, and armed with numerous sharp teeth towards the tip, for the securing its prey; black above, yellow below; bare space round the eye and pouch under the chin yellow; slit of the mouth extending beyond the eye; irides vivid red; head, neck, and all the lower parts black glossed with dark green; side of the neck, from the eye backwards for more than half its length, marked by a strip of brownish-white, consisting of long hair-like tufts of plumage extending an inch beyond the common surface, resembling the hair of callow young; a few small tufts on the crown; the whole upper parts black, marked in a very singular and beautiful manner with small oval spots and long pointed streaks of a lively white which has the gloss of silver in some lights; middle of the back, primaries, secondaries, rump, and tail-coverts plain glossy black; on the upper part of the back the white is in very small oval spots lengthening as they approach the scapulars and tertials, on the latter they extend the whole length of the feathers, running down the centre (these are black shafted); the wings long and pointed; lesser coverts marked on every feather with an oval or spade-shaped spot of white; greater coverts nearly all of a hoary-white; tail long, rounded, and exceedingly stiff, consisting of 12 broad feathers, the exterior vanes of the four middle ones curiously crimped, the whole black and broadly tipped with dirty brownish-white; thighs black; legs scarcely an inch and a half long; feet webbed, all the four toes united by the membrane, which is of uncommon breadth; exterior toe the longest, 3 inches; claws horn-colour, strong and crooked, inner side of the middle one pectinated; legs and feet yellow. All the plumage very stiff and elastic; that of the neck and breast shorter, soft, and shining. Length 2 feet 10 inches.

Female—differs in having the neck before of a cream colour or iron-grey, the breast the same, but lighter and tinged with pale chestnut; belly as in the male; where the iron-grey joins the black on the belly, there is a narrow band of chestnut; upper head and back of the neck dark sooty-brown streaked with blackish; cheeks and chin pale yellow-ochre; in every other respect the same as the male, except in having only a few slight tufts of hair along the sides of the neck; tail 12 inches long to its insertion, generally spread out like a fan, and crimped, like the other, on the two outer vanes of the two middle feathers only. Length 2 feet 9 inches. (Wilson.)

Habits.—"Here is in this river (St. Juan, East Florida) and in the waters all over Florida, says Bartram, speaking of this species, 'a very curious and handsome bird; the people call them snake-birds; I think I have seen paintings of them on the Chinese screens and other Indian pictures; they seem to be a species of Colymbus, but far more beautiful and delicately formed than any other that I have ever seen. They delight to sit in little peaceable communities, on the dry limbs of trees hanging over the still waters, with their wings and tails expanded, I suppose to cool and air themselves, when at the same time they behold their images in the watery mirror. At such times, when we approach them, they drop off the limbs into the water as if dead, and for a minute or two are not to be seen; when on a sudden, at a great distance, their long slender head and neck appear, like a snake rising erect out of the water; and no other part of them is to be seen when swimming, except sometimes the tip end of their tail. In the heat of the day they are seen in great numbers, sailing very high in the air over lakes and rivers. They inhabit the waters of Cape Fear River, and, southerly, East and West Florida.'

Mr. Abbot, of Georgia, who agrees with Wilson in opinion that *P. Anhinga* is the female of the black-bellied Darter, gives its length as 36 inches, extent 40; and says, 'These birds frequent the ponds, rivers, and creeks during the summer; build in the trees of the swamps, and those of the islands in the ponds; they construct their nests of sticks; eggs of a sky blue colour. I inspected a nest, which was

Plotus Anhinga, male.

Plotus Anhinga, female. (Wilson.)

not very large; it contained two eggs and six young ones, the latter varying much in size; they will occupy the same tree for a series of years. They commonly sit on a stump which rises out of the water, in the mornings of the spring, and spread their wings to the sun, from which circumstance they have obtained the appellation of Sun-birds. They are difficult to be shot when swimming, in consequence of only their heads being above the water.'

Localities.—The Carolinas, Georgia, and the Floridas; common in Brazil and Cayenne.

Fregata. (Ray.)

Generic Character.—*Bill* long, robust, strong, trenchant, depressed at the base, widened on the sides, with a suture above, the mandibles very much hooked at the point, and the gape very wide; *nostrils* linear; orbits naked; throat dilatable. *Wings* very long and very narrow, two first *quills* very long. *Feet* short; the toes united by a membrane which is deeply notched. This is the genus *Tachypetes* of Vieillot.

The *Man-of-War Birds*, or *Frigates*, are eminently raptorial. Ray speaks of their eagle-eye, vulturine claws, and kite-like glidings. Their immense extent of wing and dashing habits have obtained for them the name of the swiftest sailing ships of war that sweep the seas.

Mr. Vigors (*Linn. Trans.*, vol. xiv.), who, as we have seen, considers *Phaeton* and the genus before us as belonging to this family, observes that in those genera we find a still more immediate approach than we find in the closely allied cormorants to the birds of prey, in their raptorial habits, their soaring and aerial flight, and the rapid seizure of their prey without immersing themselves in the waters where they seek it. '*Tachypetes* in particular,' says Mr. Vigors, 'exhibits in its general habits and structure the most conclusive evidence of this affinity, and of its deviation at the same time from the *Natatores*. Although for the most part it pursues its habits of rapine at immeasurable distances from the shore, and derives its support exclusively from the ocean, it is never known to rest upon its surface. It does not possess in fact, to a sufficient extent, those glands which by their oily secretions preserve the plumage of other oceanic birds from the effects of the water; while the extreme disproportion of its hinder extremities deprives it of the power of either swimming or walking. On observing the structure of its legs, we immediately detect this deficiency. Short, weak, and feathered down to the toes, they are equally unsuited to the land and the water. Its powers of motion and the characters by which it maintains its station in nature are in fact centred in its wings. Supported in its unlimited flights by the strength and expansion of these members, and aided by the singular mechanism of its tail and the buoyant nature of the inflated sac which distends its throat, it seems to be an inhabitant of the air rather than of the land, where it resorts alone for the duties of its nest, or of the water, over which it only hovers for its prey. These extraordinary and strongly marked characters, by which it thus appears as it were to fluctuate between the confines of the two orders before us, did not escape the penetrating eye of Linnæus, who, by the name of *Pelecanus Aquilus* which he assigned it, pointed out at once its place among the *aquatic* birds and its vicinity to the aquiline.'

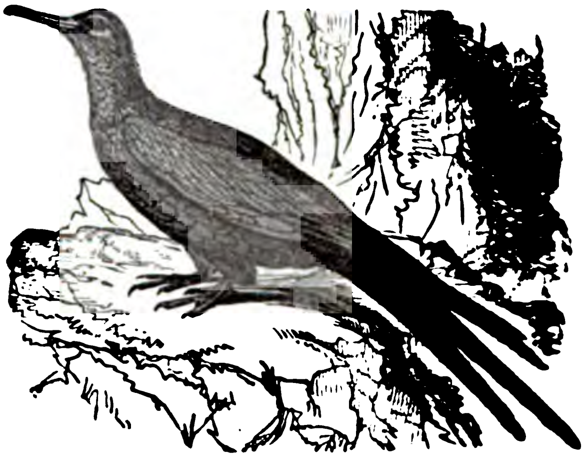
The best and perhaps the only satisfactorily defined species is that just above mentioned.

Description.—Tail forked, body black, bill red, orbits black. The male is entirely black: abdomen of the female white. Some accounts state the extent of the wings to be fourteen feet, an almost incredible expanse.

Habits.—Sloane, who saw them at Jamaica, describes them under the name of *Men-of-War Birds*, as appearing in the bay near Port Royal. 'They fly,' says he, 'like kites, look black, are very large winged in proportion to their body; they fight with sea-gulls (which are to be found here, and are like ours) for their prey.' It is however but an unequal fight, for the poor gull has not much chance when opposed to the swoop of the *Frigate*. The same author gives a much more detailed account of their habits afterwards (p. 30). He saw them together with *Tropic Birds* when he came into lat. 13° 10′. 'This bird,' remarks Sloane, in his section *Of Men-of-War Birds*, 'seems very large, bigger than a kite, and black; they fly, like kites, very high, and often appear immoveable over the water, to wait for and catch small fish appearing on the surface: they are sharp winged and their tail is forked. When flying-fishes are persecuted under water by dolphins, bonitos, &c., they rise and fly for some space in the air, and are often devoured by these birds in that time. We saw them first when we came near Barbados. The sailors guess themselves not many days, or about two hundred leagues, off the islands when they spy them first; and it is wondered how they can direct their course to the land at nights, being so far distant: but it seems no very strange matter, because they are very high in the air, and can see land much farther than those on the deck or topmast of a ship. The reason of their flying so high may be to have a greater field before them for prey, because they may go where they see the dolphins follow or hunt the flying-fishes. They are commonly thought in the West Indies to foretel the coming in of ships, for when they see a Man-of-War Bird come into their ports, they reckon ships will soon follow, and it is very often true, for they love to fish in not very rough weather, so that when it blows hard at sea, they come into the ports and bays to fish, where the wind is broken off by the land, and the same wind blowing them in brings in the shipping after them. There are more of these in the firm land of America than in the isles. One of these birds at Panama coming to take sardinas that were a curing in the sun, a negro broke his wing with a stick he had in his hand: the body, after it was clear of its feathers, was little bigger than a pigeon. The wings being extended, no man, though several tried, could reach, with his arms stretched out, within four inches of the tips of them.' The fat was considered by the Indians and others a sovereign remedy in some diseases, such as sciatica, &c.

The nest is said to be built on rocks in small desert islands, on lofty cliffs, or in high trees in retired situations near the sea. The eggs are stated to be one or two in number, and to be of carnation tinge and dotted with crimson. The newly hatched young are said to be covered with a grey down. For the tyranny with which the *Frigate* treats the unfortunate *Gannets*, see the article BOOBY, vol. v., p. 16[illegible]

Geographical Distribution.—Very common on the intertropical American coasts, and in the Atlantic and *Pacific* oceans, but always within reach of land.



Frigate, or Man-of-War Bird: the gular pouch not dilated.

PELECANOI'DES. [PETRELS.]

PELECA'NOPUS. [TERNS.]

PELECA'NUS. [PELECANIDÆ.]

PELEW ISLANDS are a chain of small islands situated in the Pacific, between 8° and 9° N. lat. and between [illegible] and 136° E. long. They extend from south-south-west to north-north-east. The group is enclosed by a reef, which surrounds it in the form of a crescent almost entirely on the west and north, and even from the east it is difficult to approach the islands on account of the reefs. There is no reef on the south, but there are several shoals of coral-rocks. The group consists of more than twenty islands of moderate extent, which are narrow and long. The largest is the island of Babeltoup, which may be nearly 60 miles in circumference. The islands of Oroorong, Cooroora, and A[illegible]tingall are much smaller. A considerable part of their surface is covered with hills, between which there are pretty extensive valleys, generally with a rich soil. The hills are covered with high trees. There are no rivers in the islands, but the inhabitants are supplied with water from brooks and ponds. When Captain Wilson was shipwrecked [illegible] there in 1783, he found no quadrupeds except rats; but now there are cattle, goats, and hogs. The sheep that were carried there have all been killed by the inhabitants for some unknown reason, but the hogs and goats thrive well. Cattle are stated to have become abundant, which is probable, as Captain Wilson found many tracts covered with grass. The vessels which make the outer passage to Canton stop at these islands for provisions. Wild fowl is numerous. There is also a large kind of blue pigeon, and a bat of enormous size. Several kinds of fish are plentiful, and some of them are of great size; sharks are common. Turtles abound, as well as shell-fish, such as oysters, mussels, and others. The principal objects of cultivation are yams, bananas, and cocoa-nut trees; but the sugar-cane and turmeric are also raised. There are betel-nut-trees, oranges, and limes, but they are not abundant. The bamboo and the bread-fruit tree grow wild in the forests, and also the cabbage-tree and a tree the fruit of which resembles almonds. The forests contain ebony, and many timber-trees of great size; a single tree is frequently converted by the inhabitants into a boat capable of carrying 25 or 26 men.

The inhabitants are a tribe of Malays. They are very good-natured, and received Captain Wilson and his crew with great kindness. They wear no clothes, and drink only water and the juice of the cocoa-nut and of the sugar-cane without distillation. Their huts are made in a very simple way, but they show some ingenuity in the construction of their boats. Their cooking utensils are made of clay, and are burned in the same manner as our coarse pottery.

(Keate's *Account of the Pelew Islands*; and Delano's *Narrative of Voyages and Travels*.)

PELICAN. [PELECANIDÆ.]

PELIDNA. [TRINGINÆ.]

PELION, MOUNT. [THESSALY.]

PELIUS. [VIPERIDÆ.]

PELL, JOHN, an eminent English mathematician, descended from an ancient family in Lincolnshire, was born at Southwick in Sussex, March 1st, 1610, where his father was minister. From an astrological horoscope, preserved among Ashmole's collections at Oxford, we learn that he was born at 21 minutes after one o'clock in the noon of that day. He received his grammar education at the free-school of Steyning in Sussex, and made so rapid a proficiency in the Latin, Greek, and Hebrew languages, that at the early age of thirteen he was sent to Trinity College, Cambridge. He never offered himself however a candidate at the election of scholars or fellows of his college. In 1631 he was admitted to an *ad eundem* degree in the university of Oxford, having proceeded to the degree of master of arts at Cambridge the previous year. In 1632 he married Ithamaria, second daughter of Mr. Henry Reginolles, of London, by whom he had four sons and four daughters. During this time he had acquired a mathematical reputation by the publication of several works, and when a vacancy occurred in the mathematical chair at Amsterdam, in 1639, Sir William Boswell, the English resident with the States-general, used his interest that he might succeed to that professorship. It was not filled up however till 1643, when Pell was chosen; and he greatly distinguished himself in this situation by his lectures on Diophantus, and on various other parts of the mathematics. In 1646, on the invitation of the Prince of Orange, he removed to the new college at Breda, as professor of mathematics, with a salary of 1000 guilders per annum. In 1652 he returned to England, but in two years afterwards, in 1654, he was chosen, by the protector Cromwell, agent to the Protestant cantons in Switzerland. He continued in Switzerland till June 23, 1658, when he set out for England, where he arrived about the time of Cromwell's death. His diaries and correspondence during this period are still preserved among the Lansdowne manuscripts in the British Museum, and are particularly curious and valuable for the history of this period. His negotiations abroad gave afterwards general satisfaction, as it appeared he had done no small service to the interest of King Charles II. and of the church of England. Having entered holy orders, he was instituted, in 1661, to the rectory of Fobbing in Essex, with the chapel of Bartlesden annexed, on the presentation of the king. In 1673 he was presented, by Dr. Sheldon, then bishop of London, to the rectory of Laindon in Essex; and about the same time he took the degree of doctor of divinity. Shortly afterwards his patron was translated to the archbishopric of Canterbury, and made him one of his domestic chaplains. Such an appointment is generally considered to be a step to higher preferment, but Dr. Pell was so intent on the philosophical and mathematical sciences, that he neglected his own interest, and was so imprudent with respect to the management of his worldly affairs, that he would have disgraced the station of a dignitary. Anthony Wood says that 'he was a shiftless man, and his tenants and relations dealt so unkindly with him, that they cozened him of the profits of his parsonages, and kept him so indigent that he wanted necessaries, and even paper and ink, to his dying day.' In the midst of his incessant application to his studies, owing to the neglect of his affairs his embarrassments increased, and he contracted debts which proved the occasion of his being twice in the King's Bench prison. Being at length reduced to great indigence, he was invited by Dr. Whistler, in March, 1682, to live in the college of physicians. Here he continued only for a few months, the ill state of his health rendering it advisable for him to remove to the house of a grandchild of his in St. Margaret's, Westminster. He afterwards removed to the house of Mr. Cothorne, reader of the church of St. Giles's in the Fields, where he died, on the 12th of December, 1685, in the seventy-fourth year of his age, and was interred at the expense of Dr. Busby, master of Westminster school, and Mr. Sharp, rector of St. Giles's, in the rector's vault under that church.

Dr. Pell's reputation as an algebraist and mathematician was great in his own time, and he deservedly holds a high position in the history of the mathematics of the seventeenth century. It was to Pell that Newton first developed his invention of fluxions; and the original letter containing his method, which was printed in the 'Commercium Epistolicum,' has been recently discovered by the late Professor Rigaud in the library of the earl of Macclesfield. Dr. Pell published the following works:—

1. 'A Refutation of Longomontanus's Discourse, De vera Circuli Mensura,' 4to., Amst., 1644, 2pp.

2. 'A Letter to Theodore Haak concerning Easter,' 4to., Lond., 1664. The original manuscript is in the British Museum, MS. Sloan., 4419. This is merely in favour of what was then called the New Style, and consists only of seven pages.

3. 'An Idea of the Mathematics.' Printed at the end of Mr. John Durie's 'Reformed Library-keeper.'

4. 'A Table of Ten Thousand Square Numbers, viz. of all the Square Numbers between 0 and 100 millions, and of their Sides or Roots, which are all the whole numbers between 0 and ten thousand,' fol., Lond., 1672. *Ff.* 16.

5. 'Rhonius's Algebra, translated out of the High Dutch into English by Thomas Branker, much altered and augmented by Dr. John Pell,' 4to., London, 1668. In this work Dr. Pell first invented the mode of registering the steps of difficult equations, which was then adopted by several writers, but has now fallen out of use; the last work that we know of which contains it is Butler's 'Introduction to the Mathematics,' published in 1815. Here also he introduced the character ÷ for division, which is now employed.

6. 'An Essay on the Day Fatality of Rome.' Printed in Aubrey's 'Miscellanies,' edit. 1721, p. 22.

Besides these, he published several single-leaf controversial pamphlets, the titles of which we have not been able to ascertain. His manuscripts and letters still remaining are numerous, and perhaps in no similar instance have papers been so carefully preserved. In the British Museum alone are nearly forty folio volumes, none of them very small, of his letters and mathematical scraps. These were supposed by Dr. Hutton to have been deposited in the library of the Royal Society, but it has been shown (Halliwell's *Life of Sir S. Morland*, p. 27-30) that they are all deposited in the Birch collection of manuscripts in the British Museum, with the exception perhaps of a few manuscript letters. In the Harleian collection there are three other similar volumes, which no doubt belonged to the same, and it is difficult to say how they could have been transferred to that library. Dr. Hutton says that he left some of his manuscripts at Brereton in Cheshire, where he resided some time, being the seat of William Lord Brereton, who had been his pupil at Breda. In August, 1644, he was preparing for the press a new edition of Diophantus, one of his most favourite books, in which he intended to correct the translation and make new illustrations, but this project was never perfected.

He designed likewise to publish an edition of Apollonius, but laid it aside in May, 1645, at the desire of Golius, who was engaged in an edition of that author from an Arabic manuscript given him at Aleppo eighteen years before. Pell's letters in the Royal Society are addressed principally to Cavendish; and one out of the series has accidentally found its way into a manuscript in the British Museum, MS. Harl., 6796.

PELLA. [MACEDONIA.]

PELLA'GRA is a disease chiefly affecting the skin, and particularly prevalent amongst the peasantry of the north of Italy. According to Dr. Holland (whose description, in the 8th volume of the 'London Medico-Chirurgical Transactions,' is by far the best that has been published in this country), the disease affects the poor almost exclusively, and among them chiefly those who are occupied in the culture of the irrigated rice-grounds, and in other parts of agricultural labour. It usually appears first as a disease of the skin, breaking out early in the spring, with slightly elevated shining dark-red blotches on the hands and feet, and sometimes on other parts of the body, accompanied by a slight pricking sensation. Soon after, small tubercles arise upon the inflamed blotches, and the skin becomes dry and scaly, and often deeply cracked. Desquamation gradually takes place, and, towards the close of the summer, or even earlier, the skin usually appears quite recovered. This, at least, is the usual progress of the first attack; and there is seldom any greater general disturbance of the health than debility, irregular pains of the body, loss of appetite, and emaciation.

In the next spring however the disease usually recurs, with a great aggravation of both the local and the general symptoms, and especially with an increase of the nervous affection, and great anxiety and despondency. In succeeding years it regularly returns with increased severity in every spring, though it does not, as at first, leave the patient nearly healthy in the autumn and winter. After the third attack, or sometimes later, the weakness of the patient commonly becomes extreme, and he has many symptoms similar to those of scurvy, with constant diarrhœa, dropsical swellings, and various nervous disorders. Its most marked character however is the total despair which fills the patients' minds, from which nothing can rouse them, and which, if the disease does not prove fatal by its effects in debilitating their bodies, generally leads to incurable idiotcy or mania. In the lunatic hospital at Milan, Dr. Holland found, among 500 patients, more than one-third in whom the insanity had been the result of pellagra, and 'even this statement gives little adequate idea of the nature of its ravages. The public hospitals are far from sufficient to receive the vast number of persons affected with the pellagra; and the greater proportion perish in their own habitations, or linger wretched spectacles of fatuity and decay.' The period during which the disease may continue is uncertain; but after the third or fourth year, there is usually little hope of benefit from any means that can be adopted. The diseases to which, in its later stages, it may lead, or with which it may be complicated, are of the most varied kinds; and there are few which, in different cases, the Italian physicians do not ascribe to its influence.

The pellagra prevails chiefly in the provinces of Lombardy between the Alps and the Po, and especially in the district between the Lago Maggiore and the Lago di Como. Among the inhabitants of these parts it has now been supposed to have existed for upwards of a century: here it appears first to have become an object of attention to physicians, and hence to have spread slowly to the Venetian and other northern provinces. It is distinctly an hereditary disease; but there is no sufficient evidence for believing it to be propagated by contagion. Its origin and prevalence are rather to be referred to the condition of poverty in which the peasantry, though the cultivators of one of the most fertile countries in Europe, are compelled to live. Their ordinary diet consists of vegetables, which are usually of inferior quality and ill-prepared: their bread, which is principally made of maize, is for the most part ill-fermented, and often deficient in salt. They rarely have any animal food, and their poverty almost entirely precludes the use of the wines of their own country. Similar wretchedness is evident in their clothing, in their dwellings, and in the deficiency of all the commonest comforts of life. They are thus constantly predisposed to the attacks of diseases of all kinds, and especially are unfit for exposure to the influence of a burning sun during severe agricultural labour. Hence the disease usually makes its first appearance when the peasants are at their most active work, and when the heat of the days is increasing; and hence it is usually first characterised by a disease of the skin, which however is but a slight indication of its future more serious and varied effects.

The treatment of pellagra offers little prospect of success so long as the patient remains exposed to the same influences by which he was rendered subject to its attack. The course usually adopted by the Italian physicians for the patients who are admitted into the hospitals is a liberal allowance of wholesome food, and the administration of wine and of tonics of various kinds. There seems little reason to doubt that if wholesome food could be constantly secured for the poor, the pellagra would speedily disappear from all the districts in which it now so fatally prevails.

PELLO'RNEUM (Ornithology), Mr. Swainson's name for a genus of *Crateropodinæ*, or *Babblers*. [MERULIDÆ.]

PELOKONITE, a mineral which occurs amorphous. No cleavage. Fracture conchoidal. Hardness 3. Brittle, but not remarkably so. Colour bluish-black. Streak liver-brown. Lustre vitreous, nearly dull. Opaque. Specific gravity 2·567. Soluble in hydrochloric acid; solution of a yellowish-green colour, and contains phosphoric acid, iron, manganese, and copper.

PELO'PIDAS, the son of Hippoclus, belonged to one of the principal families of Thebes. He distinguished himself at the battle of Mantineia (B.C. 385), in which the Thebans took part as allies of the Lacedæmonians under the Spartan king Agesipolis. In this battle Pelopidas, being wounded and thrown down, was saved from death by Epaminondas, who protected him with his shield, maintaining his ground against the Arcadians until the Lacedæmonians came to their relief and saved both their lives. From that time a close friendship was formed between Epaminondas and Pelopidas, which lasted till the death of the latter. When the Lacedæmonians surprised the citadel of Thebes and established the power of the aristocracy in that city, Pelopidas, who belonged to the popular party, retired to Athens, together with a number of other citizens. After a time he and his brother exiles formed a plan with their friends in Thebes for surprising and overthrowing the oligarchy, and restoring the popular government. Pelopidas and some of his friends set off from Athens disguised as hunters, found means to enter Thebes unobserved, and concealed themselves in the house of a friend, from whence they issued in the night, and having surprised the leaders of the aristocratic party, put them to death. The people then rose in arms, and, having proclaimed Pelopidas their commander, they obliged the Spartan garrison to surrender the citadel by capitulation (B.C. 379).

Pelopidas soon after contrived to excite a war between Sparta and Athens, and thus divide the attention of the former power. The war between the Thebans and the Lacedæmonians was carried on for some years in Bœotia by straggling parties, and Pelopidas, having obtained the advantage in several skirmishes, ventured to encounter the enemy in the open field at Tegyræ near Orchomenus. The Lacedæmonians were defeated, and thus Pelopidas demonstrated for the first time that the armies of Sparta were not invincible, a fact which was afterwards confirmed by the battle of Leuctra (B.C. 371), in which Pelopidas fought under the command of his friend Epaminondas. [EPAMINONDAS.] In the year 369 B.C., the two friends, being appointed two of the Bœotarchs (Plut., *Pelop.*, c. 24), marched into Peloponnesus, obliged Argos and Arcadia and other states to renounce the alliance of Sparta, and carried their incursions into Laconia in the depth of winter. Having taken Messenia, they invited the descendants of its former inhabitants, who had gone into exile about two centuries before, to come and repeople their country. They thus reduced the power of Sparta to the boundaries of Laconia. Pelopidas and Epaminondas, on their return to Thebes, were tried for having retained the command after the expiration of the year of their office, but were acquitted. Pelopidas was afterwards employed against Alexander, tyrant of Pheræ, who was endeavouring to make himself master of all Thessaly, and he defeated him. From Thessaly he was called into Macedonia, to settle a quarrel between Alexander, king of that country and son of Amyntas II., and his natural brother Ptolemy. Having succeeded in this, he returned to Thebes, bringing with him Philip, brother of Alexander, and thirty youths of the chief families of Macedonia as hostages. A year after he very Ptolemy murdered his brother Alexander and took possession of the throne. Pelopidas, being applied to by the friends of the late king, enlisted a band of mercenaries, with which he marched against Ptolemy, who entered into an agreement to hold the government only in trust for Perdiccas, a younger brother of Alexander, till he was of age, and to keep the alliance of Thebes; and he gave to Pelopidas his own son Philoxenus and fifty of his companions as hostages. Some time after, Pelopidas, being in Thessaly, was treacherously surprised and made prisoner by Alexander of Pheræ, but the Thebans sent Epaminondas with an army, who obliged the tyrant to release Pelopidas. The Thebans soon after, having discovered that the Spartans and Athenians had sent ambassadors to conclude an alliance with Artaxerxes, king of Persia, sent on their part Pelopidas to support their own interest at that court. His fame had preceded him, and he was received by the Persians with great honour, and Artaxerxes showed him peculiar favour. Pelopidas obtained a treaty, in which the Thebans were styled the king's hereditary friends, and in which the independence of each of the Greek states, including Messenia, was recognised. He thus disappointed the ambition of Sparta and of Athens, which aimed at the supremacy over the rest. The Athenians were so enraged at this, that they put their ambassador Timagoras to death on his return to Athens. Pelopidas after his return was appointed to march against Alexander of Pheræ, who had committed fresh encroachments in Thessaly. But while the army was on the point of starting, an eclipse of the sun took place, which dismayed the Thebans, and Pelopidas was obliged to set off with only 300 volunteers, trusting to the Thessalians, who joined him on the march. Alexander met him with a large army at a place called Cynoscephalæ. Pelopidas, by great exertions, although his army was much inferior in numbers, obtained an advantage, and the troops of Alexander were retreating, when Pelopidas, venturing too far amidst the enemy, was killed.

The grief of both Thebans and Thessalians at this loss was unbounded; they paid splendid funeral honours to his remains. The Thebans revenged his death by sending a fresh army against Alexander, who was defeated, and was soon after murdered by his own wife.

Pelopidas was not only one of the most distinguished and successful commanders of his age, but he and his friend Epaminondas rank among the most estimable public men of antient Greece.

(*Plutarch*, *Pelopidas*; Xenophon, *Hellenica*; Pausanias, ix. 13, &c.)

PELOPONNESIAN WAR is the name given to the great contest between Athens and her allies on the one side, and the Peloponnesian confederacy, headed by Sparta, on the other, which lasted from 431 to 404 B.C. The political state of Greece at the commencement of the war has been briefly described under GREECE [vol. xi., p. 427]. The war was a consequence of the jealousy with which Sparta and Athens regarded each other, as states each of which were aiming at supremacy in Greece, as the heads respectively of the Dorian and Ionian races, and as patrons of the two opposite forms of civil government, oligarchy and democracy. The war was eagerly desired by a strong party in each of these states; but it was necessary to find an occasion for commencing hostilities, especially as a truce for thirty years had been concluded between Athens and Sparta in the year B.C. 445. Such an occasion was presented by the affairs of Corcyra and Potidæa. In a quarrel which soon became a war between Corinth and Corcyra, respecting Epidamnus, a colony of the latter state (B.C. 435), the Corcyreans applied to Athens for assistance. Their request was granted, as far as the conclusion of a defensive alliance between Athens and Corcyra, and an Athenian fleet was sent to their aid, which however soon engaged in active hostilities against the Corinthians.

Potidæa, on the isthmus of Pallene, was a Corinthian colony, and even after its subjection to Athens continued to receive every year from Corinth certain functionaries or officers (ἐπιδημιουργοί). The Athenians, suspecting that the Potidæans were inclined to join in a revolt to which Perdiccas, king of Macedon, was instigating the towns of Chalcidice, required them to dismiss the Corinthian functionaries, and to give other pledges of their fidelity. The Potidæans refused, and, with most of the other Chalcidian towns, revolted from Athens, and received aid from Corinth. The Athenians sent an expedition against them, and, after defeating them in battle, laid siege to Potidæa (B.C. 432).

The Corinthians now obtained a meeting of the Peloponnesian confederacy at Sparta, in which they complained of the conduct of Athens with regard to Corcyra and Potidæa. After others of the allies had brought their charges against Athens, and after some Athenian envoys, who happened to be in the city, had defended the conduct of their state, the Spartans first, and afterwards all the allies, decided that Athens had broken the truce, and they resolved upon immediate war; king Archidamus alone recommended some delay. In the interval necessary for preparation, an attempt was made to throw the blame of commencing hostilities upon the Athenians, by sending three several embassies to Athens with demands of such a nature as could not be accepted. In the assembly which was held at Athens to give a final answer to these demands, Pericles, who was now at the height of his power [PERICLES], urged the people to engage in the war, and laid down a plan for the conduct of it. He advised the people to bring all their moveable property from the country into the city, to abandon Attica to the ravages of the enemy, and not to suffer themselves to be provoked to give them battle with inferior numbers, but to expend all their strength upon their navy, which might be employed in carrying the war into the enemies' territory, and in collecting supplies from the subject states; and further, not to attempt any new conquest while the war lasted. His advice was adopted, and the Spartan envoys were sent home with a refusal of their demands, but with an offer to refer the matters in difference to an impartial tribunal, an offer which the Lacedæmonians had no intention of accepting. After this the usual peaceful intercourse between the rival states was discontinued.

Thucydides (ii. 1) dates the beginning of the war from the early spring of the year 431 B.C., the fifteenth of the thirty years' truce, when a party of Thebans made an attempt, which at first succeeded, but was ultimately defeated, to surprise Platæa. The truce being thus openly broken, both parties addressed themselves to the war. The Peloponnesian confederacy included all the states of Peloponnesus, except Achæa (which joined them afterwards) and Argos, and without the Peloponnesus, Megaris, Phocis, Locris, Bœotia, the island of Leucas, and the cities of Ambracia and Anactorium. The allies of the Athenians were Chios and Lesbos, besides Samos and the other islands of the Ægean which had been reduced to subjection (Thera and Melos, which were still independent, remained neutral), Platæa, the Messenian colony in Naupactus, the majority of the Acarnanians, Corcyra, Zacynthus, and the Greek colonies in Asia Minor, in Thrace, and Macedonia, and on the Hellespont. The resources of Sparta lay chiefly in her land forces, which however consisted of contingents from the allies, whose period of service was limited; the Spartans were also deficient in money. The Athenian strength lay in their fleet, which was manned chiefly by foreign sailors, whom the wealth that they collected from their allies enabled them to pay.

Thucydides informs us that the cause of the Lacedæmonians was the more popular, as they professed to be deliverers of Greece, while the Athenians were fighting in defence of an empire which had become odious through their tyranny, and to which the states which yet retained their independence feared to be brought into subjection.

In the summer of the year 431 B.C., the Peloponnesians invaded Attica under the command of Archidamus, king of Sparta. Their progress was slow, as Archidamus, their commander, appears to have been still anxious to try what could be done by intimidating the Athenians before proceeding to extremities. Yet their presence was found to be a greater calamity than the people had anticipated; and when Archidamus made his appearance at Acharnæ, they began loudly to demand to be led out to battle. Pericles firmly adhered to his plan of defence, and the Peloponnesians returned home. Before their departure the Athenians had sent out a fleet of one hundred sail, which was joined by fifty Corcyrean ships, to waste the coasts of Peloponnesus; and towards the autumn Pericles led the whole disposable force of the city into Megaris, which he laid waste. In the same summer the Athenians expelled the inhabitants of Ægina from their island, which they colonised with Athenian settlers. In the winter there was a public funeral at Athens for those who had fallen in the war, and Pericles pronounced over them an oration, the substance of which is preserved by Thucydides (ii. 35-46).

In the following summer (B.C. 430) the Peloponnesians again invaded Attica under Archidamus, who now entirely laid aside the forbearance which he had shown the year before, and left scarcely a corner of the land unravaged. This invasion lasted forty days. In the meantime a grievous pestilence broke out in Athens, and raged with the more virulence on account of the crowded state of the city. Of this terrible visitation Thucydides, who himself was a sufferer, has left a minute and apparently faithful description (ii. 46, &c.). The murmurs of the people against Pericles were renewed, and he was compelled to call an assembly to defend his policy. He succeeded so far as to prevent any overtures for peace being made to the Lacedæmonians, but he himself was fined, though immediately afterwards he was re-elected general. While the Peloponnesians were in Attica, Pericles led a fleet to ravage the coasts of Peloponnesus. In the winter of this year Potidæa surrendered to the Athenians on favourable terms. (Thucyd., ii. 70.)

The next year (B.C. 429), instead of invading Attica, the Peloponnesians laid siege to Platæa. The brave resistance of the inhabitants forced their enemies to convert the siege into a blockade. In the same summer an invasion of Acarnania by the Ambracians and a body of Peloponnesian troops was repulsed; and a large Peloponnesian fleet, which was to have joined in the attack on Acarnania, was twice defeated by Phormion in the mouth of the Corinthian Gulf. An expedition sent by the Athenians against the revolted Chalcidian towns was defeated with great loss.

In the preceding year (B.C. 430) the Athenians had concluded an alliance with Sitalces, king of the Odrysæ, in Thrace, and Perdiccas, king of Macedon, on which occasion Sitalces had promised to aid the Athenians to subdue their revolted subjects in Chalcidice. He now collected an army of 150,000 men, with which he first invaded Macedonia, to revenge the breach of certain promises which Perdiccas had made to him the year before, and afterwards laid waste the territory of the Chalcidians and Bottiæans, but he did not attempt to reduce any of the Greek cities. About the middle of this year Pericles died.

The invasion of Attica was repeated in the next summer (428 B.C.); and immediately afterwards all Lesbos, except Methymne, revolted from the Athenians, who laid siege to Mytilene. The Mytilenæans begged aid from Sparta, which was promised, and they were admitted into the Spartan alliance. In the same winter a body of the Platæans, amounting to 220, made their escape from the besieged city in the night, and took refuge in Athens.

In the summer of 427 the Peloponnesians again invaded Attica, while they sent a fleet of forty-two galleys, under Alcidas, to the relief of Mytilene. Before the fleet arrived Mytilene had surrendered, and Alcidas, after a little delay, sailed home. In an assembly which was held at Athens to decide on the fate of the Mytilenæans, it was resolved, at the instigation of Cleon, that all the adult citizens should be put to death, and the women and children made slaves; but this barbarous decree was repealed the next day. [CLEON.] The land of the Lesbians (except those of Methymne) was seized, and divided among Athenian citizens, to whom the inhabitants paid a rent for the occupation of their former property. In the same summer the Platæans surrendered: they were massacred, and their city was given up to the Thebans, who razed it to the ground.

In the year 426 the Lacedæmonians were deterred from invading Attica by earthquakes. An expedition against Ætolia, under the Athenian general Demosthenes, completely failed; but afterwards Demosthenes and the Acarnanians routed the Ambracians, who nearly all perished. In the winter (426-5) the Athenians purified the island of Delos, as an acknowledgement to Apollo for the cessation of the plague.

At the beginning of the summer of 425 the Peloponnesians invaded Attica for the fifth time. At the same time the Athenians, who had long directed their thoughts towards Sicily, sent a fleet to aid the Leontini in a war with Syracuse. Demosthenes accompanied this fleet, in order to act as occasion might offer on the coast of Peloponnesus. He fortified Pylus on the coast of Messenia, the northern headland of the modern bay of Navarino. In the course of the operations which were undertaken to dislodge him a body of Lacedæmonians, including several noble ns, got blockaded in the island of Sphacteria at the mouth of the bay, and were ultimately taken prisoners by Cleon and Demosthenes. [CLEON.] Pylus was garrisoned by a colony of Messenians, in order to annoy the Spartans. After this event the Athenians engaged in vigorous offensive operations, of which the most important was the capture of the island of Cythera by Nicias, early in B.C. 424. This summer however the Athenians suffered some reverses in Bœotia, where they lost the battle of Delium, and on the coasts of Macedonia and Thrace, where Brasidas among other exploits took Amphipolis. [BRASIDAS; THUCYDIDES.]

The Athenian expedition to Sicily was abandoned, after some operations of no great importance, in consequence of a general pacification of the island, which was effected through the influence of Hermocrates, a citizen of Syracuse.

In the year 423, a year's truce was concluded between Sparta and Athens, with a view to a lasting peace. Hostilities were renewed in 422, and Cleon was sent to cope with Brasidas, who had continued his operations even during the truce. A battle was fought between these generals at Amphipolis, in which the defeat of the Athenians was amply compensated by the double deliverance which they experienced in the deaths both of Cleon and Brasidas. In the following year (421) Nicias succeeded in negotiating a peace with Sparta for fifty years, the terms of which were a mutual restitution of conquests made during the war, and the release of the prisoners taken at Sphacteria. The treaty was ratified by all the allies of Sparta, except the Bœotians, Corinthians, Eleans, and Megarians.

This peace never rested on any firm basis. It was no sooner concluded than it was discovered that Sparta had not the power to fulfil her promises, and Athens insisted on their performance. The jealousy of the other states was excited by a treaty of alliance which was concluded between Sparta and Athens immediately after the peace; and intrigues were commenced for the formation of a new confederacy with Argos at the head. An attempt was made to draw Sparta into alliance with Argos, but it failed. A similar overture subsequently made to Athens met with better success, chiefly through an artifice of Alcibiades, who was at the head of a large party hostile to the peace, and the Athenians concluded a treaty offensive and defensive with Argos, Elis, and Mantinea for 100 years (B.C. 420). [ALCIBIADES.] In the year 418 the Argive confederacy was broken up by their defeat at the battle of Mantinea, and a peace, and soon after an alliance, was made between Sparta and Argos. In the year an expedition was undertaken by the Athenians against Melos, which had hitherto remained neutral. The Melians surrendered at discretion: all the males who had attained manhood were put to death; the women and children were made slaves; and subsequently five hundred Athenian colonists were sent to occupy the island. (Thucyd., v. 1

The fifty years' peace was not considered at an end, though its terms had been broken on both sides, till the year 415, when the Athenians undertook their disastrous expedition to Sicily. [ALCIBIADES; SYRACUSE.] After the failure of that expedition (B.C. 413), the war became on the part of Athens a struggle for existence; but even then she put forth energies which might have saved her, but for her own infatuation and the gold which her enemies obtained from Persia. The events of the war, from this period to the battle of Notium (B.C. 407), have been related under ALCIBIADES. The Spartans had now, by the aid of Persian gold, obtained a fleet with which they could cope with Athens on her own element. In the year 406, Conon, who had been appointed, with nine other generals, to succeed Alcibiades, was blockaded in the harbour of Mytilene by the Spartan admiral Callicratidas. His colleagues sailed to his assistance, and completely defeated the Spartans in the battle of Arginusæ. The Spartans now made overtures for peace, which were rejected by the Athenians at the instigation of a demagogue named Cleophon.

In the following year (B.C. 405) Lysander was appointed to the command of the Lacedæmonian fleet. [LYSANDER.] He attacked the Athenians at Ægospotami on the Hellespont at a moment when they were off their guard, and entirely destroyed their fleet. This blow in effect finished the war. Lysander sailed to Athens, receiving as he went the submission of the allies, and blockaded the city, which surrendered after a few months (B.C. 404), on terms dictated by Sparta with a view of making Athens a useful ally by giving the ascendancy in the state to the oligarchical party. [ATHENS.]

The history of the Peloponnesian War was written by Thucydides, upon whose accuracy and impartiality, as far as his narrative goes, we may place the fullest dependence. His history ends abruptly in the year 411 B.C. For the rest of the war we have to follow Xenophon and Diodorus. The value of Xenophon's history is impaired by his prejudices, and that of Diodorus by his carelessness.

PELOPONNE'SUS (Πελοπόννησος), that is, 'the island of Pelops,' the ancient name of the Morea, derived its name from Pelops, who is said by later Greek mythologists to have been of Phrygian origin. Thucydides (i. 9) simply observes that he came from Asia and brought great wealth with him. He married Hippodameia the daughter of Œnomaus, king of Pisa in Elis, and succeeded to his kingdom. He is said to have subsequently extended his dominions over many of the districts bordering upon Elis, whence the whole country obtained the name of Peloponnesus. Agamemnon and Menelaus were descended from him.

The word Peloponnesus does not occur in Homer. The original name of the peninsula appears to have been Apia (Hom. *Il.*, i. 270; iii. 49), and was so called, according to Æschylus (*Suppl.*, 256), from Apis, a son of Apollo, or, according to Pausanias (ii. 5, § 5), from Apis, a son of Telchin and descendant of Ægialeus. When Argos had the supremacy, the peninsula, according to *Strabo* (viii. 371), was sometimes called Argos; and indeed Homer seems to use the term Argos in some cases as including the whole peninsula. (Thucyd., i. 9.)

Herodotus reckoned (viii. 73) Peloponnesus to contain seven different tribes, the Arcadians, Cynurians, Achæans, Dorians, Ætolians, Dryopes, and Lemnians; the four last of which tribes, he says, had migrated from other countries, but the three former were indigenous. We know however, from the traditions in Herodotus, Strabo, and Pausanias, that the Achæans were immigrants. [ACHÆANS.]

In the time of Thucydides (i. 10) the Peloponnesus appears to have been divided into five parts, namely, Laconica, Messenia, Argolis, Achaia, and Arcadia; but in that case, as Pausanias has remarked (v. 1, § 1), Elis, which for many reasons ought to be made a separate division, must have been included in Achaia or Arcadia. Pausanias treated of Peloponnesus in seven separate books, namely, the Corinthiaca, which includes Corinthia and Argolis; Laconica, Messenica, Eliaca, Achaica, and Arcadica. Modern writers usually make six divisions, Achaia, Elis, Arcadia, Argolis, Laconica, and Messenia, to which Sicyonia or Corinthia is sometimes added.

The ancient history of Peloponnesus forms part of the history of Greece. [GREECE, and the references there given.] The physical geography of the country is given under MOREA, ACHAIA, ARCADIA, ARGOS, ELIS, LACONICA, and MESSENIA.

PELOPS. [PELOPONNESUS.]

PELORIS, Poli's name for the animal of the Glycimeris, properly so called, *Cuvier*. [PECTUNCULUS.]

PELORONTA, Oken's name for a form of Nerit. *Nerita Peloronta* of authors. [NERITIDÆ.]

PELORUS, De Montfort's name for a genus of microscopic *Foraminifera*.

PELVIS. [MAN; SKELETON.]

PELUSIUM. [EGYPT.]

PEMBERTON, HENRY, was born at London in the year 1694. After studying the classics under Mr. John Ward, afterwards professor of rhetoric in Gresham College, he attended the lectures of Boerhaave in the university of Leyden, and also resided some time at Paris, where his attention was directed to anatomical manipulation, in which he appears to have excelled. About this time also he became a student in St. Thomas's Hospital, London, in order more effectually to qualify himself for the medical profession, which he was afterwards precluded from following by the delicate state of his health. In 1719 the university of Leyden conferred upon him the degree of doctor of medicine, on which occasion he read his inaugural dissertation entitled 'De Facultate Oculi ad diversas Rerum Conspicuarum Distantias se accommodandi,' Lugd. Bat., 1719, 4to., and confirmed his friendship with Boerhaave, which continued uninterruptedly till the death of the latter in 1738. In 1728 he succeeded Dr. Woodward as professor of physic in Gresham College, when he commenced a course of lectures on chemistry, which were published by his friend Dr. James Wilson in 1771, London, 8vo. At a later period he was requested by the College of Physicians, of which he was early elected a fellow, to remodel their Pharmacopœia; of which, in an improved form, he published a translation in 1746, London, 8vo. He died 9th April, 1771.

Although chemistry, anatomy, and medicine had been his chief objects of study, there were probably few departments of science in which he did not possess more than ordinary knowledge. This was particularly the case in the mathematics and astronomy, with which his writings show that he had considerable acquaintance. Besides editing the edition of Newton's 'Principia' which appeared in 1726, he published,—1, 'Epistola ad Amicum de Cotesii Inventis,' London, 1722, 4to.; 2, 'View of Sir Isaac Newton's Philosophy,' London, 1728, 4to.; and 3, 'Lectures on Physiology,' London, 1773, 8vo. His communications to the Transactions of the Royal Society, of which body he was admitted a fellow, 24th December, 1720, extend from vol. 32 to vol. 62, and among them may be noticed, 1, 'Remarks on an Experiment by which it has been attempted to show the falsity of the common opinion respecting the force of bodies in motion,' 1723; 2, 'On the Locus for three and four lines, celebrated among the ancient Geometers,' 1763; 3, 'Kepler's Method of computing the Moon's Parallaxes in Solar Eclipses demonstrated and extended to all degrees of latitude,' 1771; 4, 'Geometrical Solutions of three celebrated Astronomical Problems,' 1772, &c. Among the MSS. found by his executors were—1, 'History of Trigonometry;' 2, 'Comment on Newton's Principia;' 3, 'Treatise on Spherics and Spherical Projections;' 4, 'Dissertation on the Screw of Archimedes;' 5, 'Principles of Mercator's and Middle Latitude Sailing;' and some others enumerated in Dr. Hutton's 'Dictionary.' His library contained a choice collection of mathematical works, a large proportion of which was purchased at the sale of the library of the Abbé Gallois, which took place during his stay in Paris. The whole of them, together with those of his friend Dr. Wilson, were sold by auction soon after his death. The number of lots was 2585, and the gross proceeds 701*l.* 17*s.* 6*d.* (See *Catalogue*, with price of each lot annexed, in the library of the British Museum.)

(Hutton's *Dictionary*; Ward's *Lives of the Gresham Professors*; Thomson's *History of the Royal Society*, &c.)

PEMBROKE COLLEGE, OXFORD, was founded in the early part of the seventeenth century, on the site of Broadgate Hall, an ancient seminary for students of the civil and canon law. It originally belonged to the priory of St. Frideswide, and is believed to have been the place where the novices of that house received their first education. It was long known by the name of Segrym Hall, or corruptly Segreve Hall. It afterwards received the name of Broadgate, from the width of its entrance. It was one of the purchases which Wolsey attached to his intended college, and at the dissolution was confirmed to Christ Church by King Henry VIII., its rent being then valued at no more than thirteen shillings and four pence. Dr. John Budden, the last principal of Broadgate Hall, died in 1620.

The new foundation took place a few years after this, in consequence of a bequest from Thomas Tesdale, Esq., of Glympton in Oxfordshire. Mr. Tesdale, having bequeathed 5000*l.* to purchase estates for the maintenance of certain fellows and scholars from the free-school of Abingdon in any of the colleges of Oxford, Dr. Abbot, archbishop of Canterbury, and the other trustees, intended at first to place this foundation in Baliol College; and preparations were made, and even a portion of building was undertaken, at Baliol College for the reception and residence of Tesdale's scholars. The design however not having been carried into full effect, they determined to found a new college on the site of Broadgate Hall, and in the meantime estates were purchased for the endowment in Berkshire and Wiltshire. The plan was now assisted by a second benefactor, Richard Wightwick, B.D., some time of Baliol College, and afterwards rector of East Ilsley in Berkshire, who engaged to make over some estates in aid of the endowment.

The corporation of Abingdon next petitioned the king that he would constitute a college within Broadgate Hall, which was accordingly done by letters-patent, dated June 29, 1624, the said college to be known by the name of 'The master, fellows, and scholars of the college of Pembroke, in the university of Oxford, of the foundation of King James, at the cost and charges of Thomas Tesdale and Richard Wightwick.' It received the name of Pembroke from William Herbert, earl of Pembroke, then chancellor of the university, whose interest was liberally employed in its establishment; and it consisted of ten fellows and scholars besides the master. Four of the fellows of Tesdale's foundation are to be chosen from his relatives; two of Wightwick's must be either related to him or bear the same name. The rest are elected from the free-school at Abingdon.

One fellowship, to be held by a native of Jersey or Guernsey, was founded by King Charles I., in 1636. Sir John Benet, K.B., afterwards Lord Ossulstone, endowed two fellowships and two scholarships, about the year 1672, to which all members of the college and others are eligible who are not already on some foundation; and Sir John Philipps, Bart., founded one fellowship and one scholarship in 1749. Several scholarships and exhibitions have also been added by other benefactors. The foundation at present consists of a master, fourteen fellows, and twenty-nine scholars and exhibitioners. The total number of members whose names are on the books of the college is a hundred and eighty.

The benefices in the patronage of this college are, the rectories of Stifford in Essex, Coln St. Dennis in Gloucestershire, Sibson in Leicestershire, St. Aldates in Oxford, Ringshall in Suffolk, and Brinkworth, Codford St. Peter and Lyddiard Millicent, in Wiltshire, with the vicarage of Thurrock Grays in Essex, the donatives of Colnbrook in Berks, and Uxbridge in Middlesex, and the curacies of West Haroldston and Lambston in Pembrokeshire.

Among persons of note educated in this college are Edmund Bonner, bishop of London; Sir Thomas Brown; Carew, earl of Totness; Pym; Blackstone; Shenstone; Dr. Samuel Johnson; and Newcome, archbishop of Armagh.

The greater portion of the buildings of Pembroke College are of a date subsequent to the foundation, but the hall is the same that belonged to Broadgate. The chapel is a late building, consecrated in 1732.

(Chalmers's *Colleges and Halls of Oxford; Oxford Univ. Calendar for* 1840.)

PEMBROKE HALL, CAMBRIDGE, now more generally called **PEMBROKE COLLEGE**, was founded under the name of Valence-Mary, by Mary de St. Paul, the widow of Aymer de Valence, earl of Pembroke, in 1347, when she endowed it with estates for the maintenance of a master, six fellows, and two scholars. King Henry VI. is said to have trebled the revenues of the college by bestowing on it the priory of Linton, with its appurtenances, and the rectory and manor of Soham. His liberality obtained him the name of a second founder.

The present number of fellowships in this college is fourteen, open to all persons, with this limitation, that no more than three shall be filled by natives of the same county,—London and Middlesex however being reputed separate counties. There is also in the election to that fellowship which was established by Archbishop Grindal, formerly master of the college, a preference given to a scholar educated at St. Bees' school in Cumberland. Although there may be no fellowship vacant, yet a candidate is never considered as superannuated. When more than ten of the fellowships are filled, six of the fellows must be in orders.

There are also two by-fellowships, one founded by William Smart, Esq., of Ipswich, with a preference for the scholars on his own foundation in this college; the other founded by Benjamin Lany, D.D., formerly bishop of Ely and master of this college

The scholarships belonging to this college are numerous, viz. six foundation scholarships, of the yearly value of 28*l.* each; eight Greek, seven founded by Thomas Watts, D.D., and the other by Thomas James, Esq. Of these the four senior scholarships are of the yearly value of 14*l.* each, and the four junior of the yearly value of 12*l.* each. Six scholarships, two founded by William Smart, Esq., and four by Ralph Scrivener, Esq., of the yearly value of 5*l.* each, with a preference for those who have been educated at the grammar-school at Ipswich; three, founded by Archbishop Grindal, of the yearly value of 28*l.* each, for scholars educated at St. Bees' school. There are several others founded by Serjeant Moses, who presided over the college during the time of the Commonwealth, of the yearly value of 50*l.* each, for scholars educated at Christ's Hospital, which exhibitions they hold in addition to others, of the yearly value of 60*l.* each, allowed by the governors of the school, one of the yearly value of 70*l.*, founded by Mr. John Holmes, for a scholar educated at Blackrode school in Lancashire; six, founded by Charles Parkin, M.A., formerly rector of Oxburgh in Norfolk, of the yearly value of 50*l.*; of these, five are for scholars of Merchant Tailors' school, and the other for a scholar of the free-school at Bowes in Yorkshire; when there are no candidates, these scholarships are at the free disposal of the master of the college; one, founded by William Stuart, D.D., formerly chancellor of the diocese of Exeter, of the yearly value of 80*l.*, for a superannuated scholar of Merchant Tailors' school; and one, of the yearly value of 6*l.*, founded by Roger Long, D.D. Besides these there are several exhibitions founded by Robert Mapletoft, D.D., formerly master, and by others, to which the college have made such an addition that three sizars may have 12*l.* each yearly. The enjoyment of one scholarship does not preclude a deserving person from holding others on different foundations.

The benefices in the patronage of this college are, the rectories of Rawreth in Essex, Orton Waterville in Huntingdonshire, Cawston and Sall in Norfolk, and Framlingham and Earl Stonham in Suffolk, with the vicarages of Soham in Cambridgeshire, Waresley in Huntingdonshire, and Saxthorp and Tilney in Norfolk.

Among the more eminent members of this foundation may be reckoned the Archbishops Grindal and Whitgift, Bishop Fox, Bishop Ridley, and Bishop Andrews; Spenser, Gray, and Mason, the poets; Dr. Long, one of the masters, an eminent astronomer; Stanley, editor of Æschylus; and the late Right Hon. William Pitt.

Pembroke Hall, situated on the east side of Trumpington Street, consists of two courts of nearly the same dimensions, about 95 feet by 55. The hall which divides the two courts is about 42 feet by 27. On the east side of the inner court is a small detached building, erected for the purpose of containing a large hollow sphere, used as a lecture-room. The chapel was built by Matthew Wren, bishop of Ely, after a design by his nephew Sir Christopher Wren. It was dedicated in 1665.

A copy of the statutes of this college is preserved in the British Museum, in the Harleian MS. 734. The visitor is the queen. The number of members on the boards of the college, March 18, 1840, was 129, four fellowships being vacant.

(Lysons' *Magna Brit.*, Cambr., p. 105-107; Dyer's *Hist. Coll. and Halls of Cambr.; Cambr. Univ. Calendar*, 184[illegible]

PEMBROKESHIRE is a maritime county, forming the extreme west of South Wales: it is bounded on the east by the counties of Carmarthen and Cardigan, on the other sides by St. George's and the Bristol channels. The length from St. David's Head to the borders of Carmarthenshire is [illegible] miles; from Strumble Head on the north coast to St. Gowan's Head on the south, 31 miles. Pembrokeshire is about 150 miles in circumference, with a very irregular coast-line above 100 miles in extent: it contains about [illegible] square miles, or 368,000 acres. The gross population in 1831 was 81,424, being an increase of 9 per cent. on the census of 1821. Haverfordwest, the county town, is [illegible] miles distant from London by the mail-coach road; and its bearing and distance in a direct line is west-half-north [illegible] miles. In amount of population Pembrokeshire is [illegible] fourth of Welsh counties, and forty-first of England and Wales.

Surface; Coast; Rivers.—Pembrokeshire has no very marked features. The surface is generally undulating, without any extensive plains, or mountains of very great elevation. Being surrounded on three sides by the sea, and intersected by the great æstuary of Milford Haven, the course of the rivers is short, and there are consequently none of magnitude. The south-west winds are very injurious to the growth of timber, of which there is little except in sheltered valleys; the want of it gives a barren appearance to many parts of the country where the soil is good. The Precelli mountains, a range running from near Fishguard to the borders of Carmarthenshire, are about 10 miles in length, and attain a height of 1754 feet above the sea. The Trafgarn ridge is 673 feet high. The highest land in the southern district is Bolton Beacon, 327 feet.

The river Teivi runs into the sea with a northerly course at the northern extreme of the county; the mouth is impeded by a dangerous bar. At Cilgerran and St. Dogmaels are two villages, whose inhabitants support themselves chiefly by fishing. Proceeding along the coast to the westward for about 8 miles, is the town of Newport, once of considerable importance, but now decayed. Six miles farther Fishguard stands on a bay formed by the æstuary of the river Gwain. This bay is about 3 miles across from east to west, with from 30 to 70 feet of water in good holding-ground.

of sand and mud; it is open to the north-west, but is the only port of shelter on the west coast of Wales. In Whitesand Bay there are some remarkable hillocks of blown sand. Off St. David's Head, 51° 54′ N. lat., 5° 17′ W. long., lies a cluster of small islets called the Bishop and his Clerks. The coast here turns to the southward, and shortly after forms the bay of St. Bride, about 9 miles broad and as many in depth; off the southern point of the bay there are several small islands. There are two lighthouses on St. Anne's Head, at the north entrance of Milford Haven. This great estuary, called in Welsh Aber-dau-Gleddau, or the mouth of the two Cleddaus, is about 20 miles in length from St. Anne's Head to the confluence of the East and West Cleddau; the mouth is about 2 miles wide, and it varies from that width to half a mile throughout. It contains numerous bays and creeks, completely landlocked, free from shoals and rocks, with excellent anchorage from 5 fathoms upwards, and forms one of the finest harbours in the world. The southern coast presents a wild and inhospitable appearance; the carboniferous limestone forms precipitous cliffs 150 feet high, without any port before we arrive at Tenby, a town which is situated near the south-east extremity of the county. The coast-line is extremely irregular, but the general bearing from the mouth of the Teivi to St. David's Head is west-south-west, from thence to St. Gowan's Head south-east, and from St. Gowan's Head to the boundary in Carmarthen Bay north-east by east (true). Off St. David's Head lie Ramsey Island and the Bishop and his Clerks; off the southern point of St. Bride's Bay, the islands of Skomer, Skokham, Grasholm; and 15 miles east, the Smalls lighthouse on a rock. Caldy Island lies about 3 miles south from Tenby, and has a lighthouse on it.

Pembrokeshire has no rivers of importance. The two rivers Cleddau or Cleddy are the principal: the eastern branch rises in the Precelli mountains; the western in the north-west part of the county near St. Catherine's, runs by Haverfordwest, from whence it is navigable for small vessels, and, uniting with the East Cleddy about 5 miles below that town, falls into Milford Haven. The other rivers are the Nevern, which empties itself into the bay of Newport, the Gwayn at Fishguard, and the Solva into St. Bride's Bay.

The mail-coach road from London enters Pembrokeshire near Tavernspite. The mail arrives at Hobbs' Point, the station of the Irish steam-packets, at 12h. 34m. A.M., and at Pembroke, 261 miles from London, at 1h. 5m. A.M., quitting that town for London at noon, and Hobbs' Point at 12h. 20m. The principal cross-roads are from St. David's through Fishguard and Newport to Cardigan, 32 miles; St. David's to Haverfordwest, 16 miles; Tenby to Pembroke, 10 miles. There is a railroad from the coal-mines at Kingsmoor to the sea at Saundersfoot.

Climate.—The climate of the southern part of Pembrokeshire is mild, and not subject to great variations of temperature, but the atmosphere is frequently charged with saline exhalations from the Atlantic during south-west winds, and is consequently damp. The higher or northern part of the county has a considerably lower temperature.

Geology.—If a line be drawn through the centre of Pembrokeshire from east to west, we find the stratified rocks north of that line composed of slates, grit, and shales; to the south the older rocks are surmounted by the Silurian rocks, old red-sandstone, carboniferous limestone, and coal-measures. The whole surface is greatly diversified by trap-rocks bursting forth in many places, and altering the structure of the sedimentary deposits. The anthracite, stone-coal, or culm tract bisects the county; it is a continuation of the great basin of South Wales, covering the whole coast of Carmarthen Bay. The northern edge, commencing near Telpyn Point, runs about west by north to the Cleddy opposite Slebech; then, with a westerly direction, by Harroldston St. Issels, where the older Silurian rocks wedge into it, to a quarter of a mile from the sea in St. Bride's Bay; it there widens, and runs north as far as Brawdy. The southern edge, commencing at Tenby, bears the same general direction, crossing the Cleddy at Cherit; the band narrows to three miles south of Haverfordwest, and again spreads out towards St. Bride's Bay. The culm is contained in beds of shale and sandstone, overlying millstone-grit and carboniferous limestone. The seams vary from three feet to a few inches in thickness, and abound in dislocations and contortions. The fossil plants are the same as in other coal-fields, *Neuropteris gigantea*, *Pecopteris cuneifolia*, &c., together with various Lepidodendra and Calamites, which, from their fractured condition, are indeterminable. The millstone grit passes upwards into the coal, and downwards into the carboniferous limestone. It is generally a hard, whitish, siliceous sandstone, intractable for building, but excellent for the roads. The carboniferous limestone dips beneath the millstone-grit, forming a girdle round it in the eastern district, but disappearing in the west; a spur runs off from Carew, and terminates at Pembroke dockyard; another band extends from between Giltar Point and Old-castle Head on the south coast to West Angle Bay at the mouth of Milford Haven, where it is about a quarter of a mile wide. Pembroke stands upon this band. The southern part of the county, from Stackpole on the east to near Castle Martin on the west, is of the same formation, and being bounded on three sides by the sea, presents a greater extent of carboniferous limestone to the view than is anywhere else laid open in Great Britain. The cliffs are about 150 feet high, almost everywhere abrupt, and full of fractures and contortions. There are frequent funnel-shaped cavities and fissures, to which the sea has access. Of these the most remarkable is Bosherston Mere. It is about 100 yards from the sea; and at times, when a heavy surf beats on the shore, reports as loud as artillery are heard from it, while it throws up jets of water forty or fifty feet. There are also many cauldron-shaped hollows, which are filled with trees that could not bear upon the plain surface exposure to the south-west gales. Several species of fossil Spirifera and Terebratulæ are found in the formation. The old red-sandstone enters Pembrokeshire near Tavernspite; throwing out a promontory at Cyffic, it girdles the carboniferous limestone, and tapering away, disappears opposite Slebech. This is the only development of old red-sandstone near the coal-field; all the others are to the south of it, supporting the carboniferous limestone in long ridges. It is generally of a red colour, though there are considerable tracts of grey and yellowish sandstone. No organic remains have been discovered in the Pembrokeshire sandstone. The next in order are the Silurian rocks, comprising all those strata of more antient formation which were included under the names of grauwacke and transition limestone, until classified by R. I. Murchison, Esq. These form a narrow band rising from beneath the old red-sandstone, and contain specimens of Asaphus, Terebratula, Trinucleus, Orthis, Leptæna, &c. Rocks of igneous origin protrude in many places. From Roche Castle near St. Bride's Bay, in a north-east direction, a ridge of trap, called Trefgarn ridge, 673 feet high, runs to Ambleston, and appears again at intervals along the Precelli range. Another ridge from Benton Castle, with an interruption from a narrow band of the upper Silurian rocks, supports the coal-field, is then covered by it, and reappears on the sea-coast in the south part of St. Bride's Bay. Bolton Beacon, 327 feet, the highest ground in south Pembrokeshire, is on this ridge.

The whole of the northern district is composed of rocks of the Cambrian system of Professor Sedgwick, interspersed with occasional protrusions of the igneous rocks. There are no fluvial or lacustrine deposits in Pembrokeshire. Between St. David's and Whitesand Bay, at the bays of Freshwater East and West, and near Stackpole promontory, there are considerable hills of blown sands, extending sometimes more than a mile inland, covering hills at heights of 150 feet above the strand, and containing a prodigious quantity of land-shells, three or four species of Helices and Bulimi. These hills seem to have remained stationary. At Gupton Burrows, Newgale Sands, and St. Bride's Bay are two examples of forests submerged by the ocean, where, after severe storms, the sands being washed away, a stratum of clay and peaty earth appears, through which the stumps of trees are seen in a growing position. Copper-ore has been found in small quantities in the neighbourhood of St. David's, but not sufficient to repay the cost of working. Slate quarries are opened in the Precelli mountains and near St. David's; the quality of the slates is inferior to those of North Wales. Coal is the only mineral besides slate which is worked in Pembrokeshire: it is of that description called anthracite, or stone-coal, the dust or smaller portion of which is known in commerce by the name of culm. The best coal and culm are raised at Landshipping, on the shore of Milford Haven. A considerable quantity of good coal is also raised at Kingsmoor and Kilgetty, from whence it is conveyed by a railway to the sea at Saundersfoot, where a dock has been built.

Soil; Agriculture.—The geological formations of this county presenting great variety, it follows that the soil in different quarters is equally various. On the southern part of the county, the limestone and old red-sandstone formations afford soils of excellent quality: some districts near St. David's, and along the coast towards Fishguard, are considered to be extremely well adapted for the growth of barley; but in the coal district and the slaty ridge of the Precelli mountains, the land is very inferior. The state of agriculture is as various as the soil: in the hundreds of Castle Martin and Roos, and part of Narberth, a better system of husbandry prevails than in the upper or Welsh district, although this is very far from being such as would be approved by a scientific agriculturist. Considerable advance has been made within the last few years, although a general want of capital among the farmers presents a great check to any rapid progress. The breed of black cattle, known by the name of the Castle Martin breed, are bought in droves, for the supply of the London market principally, where they bear a tolerably good character. The breed of horses is much esteemed; they are rather small-sized. Leases for lives were formerly the most usual tenures. The farm buildings, from this reason, were, with the exception of certain properties, small, and in bad condition. The tenants grew crop after crop until the land was exhausted, and the landlord was but an annuitant on his own estate. A better system of leasing tenements now prevails, and few old leases are renewed. The farms vary in size from 30 acres to 800 and 1000, the great proportion being from 100 to 200 acres. The candidates for small farms being far more numerous than for the farms of greater size, the rents of the former are higher in proportion. Farms in the good soils let from 1*l.* to 1*l.* 15*s.* per acre; decreasing to 10*s.*, 7*s.*, and even 3*s.* The cottages are generally built with mud walls, a low thatched roof, a round wattle and daub chimney starting up from the front wall, close by the door. Farm servants are kept in the house. Labourers live in their own cottages. The condition of the poor varies greatly: the poor-rates are very high at St. David's and Wiston, and very low at Tenby.

Divisions.—Pembrokeshire is divided into seven hundreds, viz.:—

Narberth,	to the South-East,	11,942	Inhabitants.
Castle Martin,	South,	5,024	„
Roos,	West,	13,455	„
Dewisland,		10,358	„
Kemys,	North,	14,818	„
Kilgerran,		5,021	„
Dungleddy,	Centre,	7,839	„

There are 148 parishes, of which three are partly in Caermarthenshire, and seven market-towns. Three members are returned to parliament from Pembrokeshire; one for the county, one for Pembroke, and one for the Haverfordwest district of boroughs.

Haverfordwest, the capital town, is situated on the West Cleddy, on the sides and at the bottom of very steep hills. Haverfordwest, with the contributory boroughs of Narberth, Fishguard, and St. David's, returns one member to parliament. The borough contained in 1831, 4139 inhabitants. By the Municipal Corporations Act the council consists of 4 aldermen and 12 councillors. The vicarage of St. Mary's, in the gift of the corporation, has a net income of 131*l.* The rectory of St. Thomas, patron the Prince of Wales, 319*l.* The perpetual curacy of St. Martin's 80*l.* Haverfordwest is principally occupied by shopkeepers, mechanics, and persons of moderate independent fortune, for whom the cheapness of the place is an attraction. House-rent is not low compared with other parts of Pembrokeshire. Wages are low; but a good mechanic earns from 14*s.* to 20*s.* a week. Coals are brought from Newport, Monmouthshire, and Liverpool. The poorer classes use the stone-coal broken small, and made into balls with clay. This fuel gives great heat, but has an unpleasant smell. The streets of Haverfordwest are narrow, ill-paved, steep, and slovenly, but the town contains many excellent residences. The river Cleddy is navigable at spring-tides to Haverfordwest, for vessels of 100 tons burthen; at neaps, for little above 30 tons.

Fishguard, 16 miles from Haverfordwest, and a contributory borough, is increasing though slowly in size, but it is not very flourishing. It contains about 2000 inhabitants. The vicarage, in the patronage of the crown, is worth 111*l.* per annum. In the neighbourhood of the town, meadow-land lets at 4*l.* an acre: in the rest of the parish the average is about 15*s.* There are some farms as large as 300 acres, d some let as low as 5*l.* a year; the tenures are various, for , for terms, and from year to year. Corn and butter are orted; coal, culm, limestone, and shop goods imported. On the 20th February, 1797, a French force of about 1400 men landed here, who, after a few days' rioting and disorder, surrendered to 600 yeomanry and inhabitants hastily armed.

Narberth, contributory to Haverfordwest, and 11 miles distant from that town, on the high road to London, has a population of 2589. It is ill-built and not paved, but is an active, thriving, and increasing place, being the central point of a large district, which is supplied by it with shop goods. Houses are continually building, chiefly 15*l.* or 20*l.* houses, the rents are high, and they are speedily occupied. The average size of farms in the neighbourhood is 30 acres. The rectory of St. Andrew with the curacy of Robeston-Wathen is in the gift of the crown; the net income is 417*l.*

St. David's, a contributory borough, at the extreme west of the county, 1 mile from the sea, 16 miles from Haverfordwest, was once the seat of the bishops, but is now an inconsiderable village, with about 1000 inhabitants. The roads are very bad on all sides. It is inhabited almost exclusively by the clergy who perform the duties of the cathedral, some farmers, and cottagers, a few of which last live by working the peculiar kind of woollen stuff worn by the natives of Sout Wales. The poor-rates are very high, but house-rent so low, that a house which in the neighbourhood of London would let for 150*l.*, cannot let here at 8*l.* The largest farm contains 80 acres. The benefice is a perpetual curacy, of the net value of 110*l.* per annum, in the gift of the chapter. The corporation of the cathedral church consists of six canons, who divide between them an average net income 135*l.*, eight vicars choral, of whom four or five are priests, and a lay vicar, always organist; a treasurer, with an income of 46*l.*; precentor, 86*l.*; chancellor, 30*l.*; and eight prebendaries of whom the net income of the highest is 26*l.*, and the lowest 1*l.*

Pembroke lies in a rich country on a navigable creek of Milford Haven. The town consists of one long street, running east and west, and gradually ascending to the castle which is situated on an abrupt rocky promontory at the west end. Pembroke, with Tenby, Wiston, and Milford returns a member to parliament. By the Municipal Corporations Act, Pembroke is divided into two wards, the corporate body consisting of six aldermen and eighteen councillors. The parliamentary and municipal boundaries are coincident here and at Haverfordwest. The population in 1831 was 6511. The size of the farms in the agricultural part of the borough varies from 50 to 250 acres; there is one farm of 400 acres. Leases are generally for lives. The three parishes of St. Michael, St. Mary, and St. Nicholas, which are united for ecclesiastical purposes, are in the patronage of Sir John Owen: net income 439*l.* In the parish of St. Mary about 2 miles from Pembroke, on the shore of Milford Haven is situated the naval dockyard and arsenal, which was removed hither from Milford in 1814. This is the most important establishment in the county; it occupies about 60 acres of land, and when the improvements contemplated and in progress shall be completed, it will be the finest building-yard in the kingdom, capable of having on the stocks at the same time five or six first-rates, and a considerable number of ships of smaller size. The station of the Waterford steam-packets is at Hobb's Point.

Tenby, a small seaport at the western extreme of Carmarthen Bay, 12 miles from Pembroke, and one of its contributary boroughs, has 1942 inhabitants. There is little trade at Tenby: it is chiefly supported by its merits as a watering-place, for which it is well adapted both by the beauty of its scenery and the protection afforded by the neighbouring headlands. Some of the Plymouth and Brixham fishing boats make Tenby their station during the fishing season. The rectory is in the gift of the Prince of Wales; net income 317*l.*

Milford, 13 miles from Pembroke, over the ferry [illegible] the usual road, which is very bad, and the ferry very expensive—population about 4000—was a highly prosperous town till the removal of the dockyard and packet establishment. The custom-house and quarantine establishments are situated here. Farms in the neighbourhood vary from 25 acres to 250: land near the town lets at 4[illegible] acre; at a distance, about 1*l.*

Wiston, with 745 inhabitants, contributes to the Pembroke district of boroughs: it is 8½ miles direct from Pembroke, [illegible] the road is very circuitous; and 4½ miles from Haverfordwest. The perpetual curacy, in the patronage of the earl of Cawdor, has a net income of 164*l.* There are farms as small as 12 acres, and one as large as 320; they are chiefly let from year to year, one on lease for life, but none for a term.

Mining Industry, Manufactures, and Commerce.—It has been already observed that coal and slate are the only minerals worked in Pembrokeshire. The mines of coal are situated on Milford Haven, and in the parishes of Begelly and St. Issell's, from whence a railway has been constructed to convey the produce to Saundersfoot in Tenby Bay, where a dock has been built.

Pembrokeshire has no manufactures worthy of notice. Some hats are manufactured at Narberth, and the cottagers work the coarse woollen fabric usually worn by the Welsh peasantry. The commerce is very limited; the exports are coal, culm, and agricultural produce; the imports chiefly timber from Canada and shop goods from Bristol. The fisheries on the north coast were formerly valuable, but the fishermen neglect all but the salmon and shell-fish. The fishing-boats of St. Dogmael's are from 7 to 20 tons burthen, with from 5 to 6 men each.

Ecclesiastical Division.—Pembrokeshire is in the province of Canterbury, and the diocese of St. David's, and, with the exception of a few parishes in the northern part of the county belonging to the archdeaconry of Cardigan, in the archdeaconry of Carmarthen. There are 148 parishes, of which three are partly in Carmarthenshire, and 131 benefices, the average net income of which is about 134*l.*, the highest being 439*l.*; there are only three exceeding 300*l.* per annum.

Assizes are held in spring and summer at Haverfordwest, and quarter-sessions four times a year at the same place.

Civil History; Antiquities.—Pembrokeshire, which name is derived from *pen*, head or end, and *bro*, an inhabited land, anciently formed part of the territory of the Dimetæ. Giraldus Cambrensis informs us that it was conquered in the reign of Henry I. by Arnulf de Montgomery (brother to the earl of Shrewsbury), who built the first castle of Pembroke of stakes and turf. In the same reign a colony of Flemings settled in that part of the county west of the Cleddy, who still retain their nationality completely distinct, and the district is hence termed "Little England beyond Wales." Richard II. landed in Milford Haven on his return from Ireland, in 1399, at the commencement of the insurrection which preceded his dethronement. Henry Tudor, earl of Richmond, afterwards Henry VII., landed in Milford Haven, August 7, 1485, with about 2000 men, and marched hence towards Shrewsbury, greatly increasing his army by the way, for the Welsh favoured both his cause and family. Pembroke has given the title of earl to several noble families. King Stephen bestowed it upon Gilbert Strongbow, son of Gilbert de Clare; through his granddaughter Isabella it passed into the family of Marshall. Henry III. gave this title to his half-brother William de Valentia or Valence, from whose family it passed by the female line into that of Hastings. The dukes of Bedford and Gloucester, sons of Henry IV., also enjoyed it, as did William de la Pole. Edward IV. created his son earl of Pembroke. Edward VI. created William Herbert earl of Pembroke, which family possesses the title.

Pembrokeshire is rich in antiquities. St. David, soon after the British synod held in 519 for the purpose of suppressing the Pelagian heresy, is said to have built a monastery at Vallis Rosina, situated near Menevia (St. David's), the monks to support themselves by the labour of their own hands. St. David translated the archiepiscopate hither from Caerleon in the sixth century, whence the town took his name. This see was generally full, and enjoyed the archbishopric until 930, when archbishop Sampson carried off the pall with him to Dôle in Normandy. The cathedral, which was built in the thirteenth century, is in the form of a cross, having a square tower, with pinnacles rising from the centre, at the intersection of the north and south transepts. The interior consists of a nave, two side aisles, a choir, and chancel. The nave is separated from the aisles by two rows of columns alternately round and octagonal, five in number, with pilasters at each end supporting circular arches. Over these a range of round pillars support smaller arches reaching to the roof. The ceiling is of Irish oak, in square compartments of elegant workmanship. The length of the nave is 124 feet; the width of the same, 41 feet; aisles, 15 feet. The length of the whole building within, 307 feet. The architecture is Norman mixed with the early pointed order. Some of the arches of the gallery are Norman, but the greater number are Gothic. The architraves are highly ornamented with frets, diagonals, and foliage. The choir is placed immediately under the tower, which is supported by three Gothic and one Norman arch, all springing from Norman pillars. The bishop's throne, at the south-east angle of the choir, is of carved oak, unequalled in beauty save by that of Exeter. A low screen separates the chancel from the choir. The floor of the chancel is of small square variegated tiles. The roof is painted, and enriched with the arms of benefactors. There are 28 stalls carved. In the nave are several monuments of bishops and other dignitaries. Opposite the entrance to the chancel is an altar tomb to Edmund Tudor, earl of Richmond, son of Owen Tudor, by Catherine, widow of Henry V., and father to Henry VII.; also the shrines of St. David, of Rhys ap Gryffydd, prince of Wales, of his son, and of two bishops. The north transept is occupied by a chapel dedicated to St. Andrew. Adjoining the cloisters are the fine remains of the collegiate church of St. Mary's, founded by John of Gaunt, Blanche his wife, and bishop Adam Houghton conjointly. The palace of St. David's, a magnificent ruin, was erected, in 1335, by Bishop Gower; it is built round a court 120 feet square. The bishop's hall, on the south-east side, is 88 feet by 23; the king's, on the south-west side, 58 feet by 30. These two sides alone remain. An open arched parapet in the Gothic style adds greatly to its external beauty.

Pembroke Castle stands on the extremity of an elevated rocky promontory, running from east to west. Giraldus Cambrensis informs us that it was built in the time of Henry I. It is of Norman architecture mixed with early Gothic. The principal tower remains perfect. During the civil wars of Charles I. this castle made a gallant defence for the crown, under Colonels Laugharne and Powell; it was taken and dismantled by Cromwell, in 1648. Under the keep is a spacious natural cavern called the Wogan, about 80 feet by 60. Henry VII. was born in this castle. Manorbeer Castle, near Tenby, is an extensive ruin, whose many remains prove it to have been formerly a place of importance; it was founded by the family of Barri, of which Giraldus Sylvester, surnamed Cambrensis, was a member. He was born here, and the church contains a sepulchral effigy of him. Near St. Gowan's Head is a cell cut in the face of the steep cliff, inaccessible except by a flight of steps. Here St. Gowan lived, and performed miraculous cures. Lame and blind pilgrims are still conveyed hither by their friends, anointed with a poultice of the clay formed by the decomposition of the limestone, and left there to bask in the sun. It is also frequented as a wishing-place; the visitor, if he performs certain ceremonies with due faith in their efficacy, is certain of having his wish fulfilled within the year. At Lamphey, or Llantfydd, near Pembroke, are the remains of a former palace of the bishops, alienated to Henry VIII., and by him granted to Walter Devereux, afterwards Viscount Hereford.

Cilgerran Castle, on the Teivi, was built by Marshall, earl of Strigul (Chepstow), after he had conquered Gryffydd, prince of Wales, in 1223. Near the mouth of the same river are the remains of the monastery of St. Dogmael, founded by Martin of Tours, who conquered the land of Kemmes, in the reign of William I.; it was endowed and made an abbey in the time of Henry I., and dedicated it to St. Mary. The island of Caldy belonged to St. Dogmael's.

Picton Castle, at the confluence of the two Cleddys, was built in the reign of William Rufus. A preceptory of the knights of St. John of Jerusalem was established at Slebech before 1301. Pill Priory was founded by Adam de Rupe, in 1200, of the strict order of Benedictines, called Tyron. At Nevern near Newport there is a curious British cross, formed of a single stone, two feet broad, eighteen inches thick, and thirteen feet high, richly decorated. Near Pentre-Evan, in the same parish, is a cromlech, probably one of the largest in the kingdom. There are several other Druidical remains in the neighbourhood. The church of Nevern is a very venerable pile, and one of the largest in the county. Besides the remains above enumerated are the castles of Carew, Narberth, Haverfordwest, Benton, Llahaden, Newport, Roch, Tenby, castles in Pulslater Bay near Pembroke, the priory and bridge of Haverfordwest, Llanfeth Court, &c.

STATISTICS.

Population.—According to the census of 1831, of 18,356 males twenty years of age and upwards, 1599 were labourers engaged in non-agricultural employments; 9781 males aged twenty and upwards were employed in agriculture, of whom 6075 were labourers; 1842 were occupiers of land employing labourers; and 1864 occupiers not employing labourers. The number employed in manufactures or in making manufacturing machinery was 131. There were about 130 weavers of woollen cloth and flannel in the county, but the largest number at any one place was no more than 17, at St. David's. The mines and quarries afforded employment to a considerable number of labourers, and 324 males aged twenty years and upwards were employed as shipwrights and boat-builders.

The population of Pembrokeshire, at each of the four following periods, was:—

	Males.	Females.	Total.	Increase per cent.
1801	25,406	30,874	56,280	..
1811	27,453	33,162	60,615	7
1821	34,530	39,479	74,009	22
1831	37,952	43,473	81,425	9

showing an increase between the first and last periods of 25,145, or rather more than 44½ per cent. on the whole population, being 2½ per cent. above the rate of increase for the whole of Wales.

The following table exhibits a summary of the population of every hundred, &c., as taken in 1831:—

HUNDREDS, BOROUGHS, AND TOWNS.	HOUSES.				OCCUPATIONS.			PERSONS.			
	Inhabited.	Families.	Building.	Uninhabited.	Families chiefly employed in Agriculture.	Families chiefly employed in trade, manufactures, and handicraft.	All other Families not comprised in the two preceding classes.	Males.	Females.	Total of Persons.	Males, twenty years of age.

Totals .	15,779	16,595	164	474	7,974	4,519	4,102	37,592	43,473	81,425	18,356

County Expenses, Crime, &c.—The sums expended for the relief of the poor, at the following dates, were—

	£.		s.	d.	
In 1811	20,390,	being	6	8	for each inhabitant.
In 1821	20,245	„	5	5	„
In 1831	24,552	„	6	0	„

The expenditure in each of the following years was as under:—

1834.	1835.	1836.	1837.	1838.
£.	£.	£.	£.	£.
25,593	23,119	22,580	21,833	21,576

In 1837-8 the amount for each head of the population, according to the census of 1831, was 5*s.* 4*d.*; but assuming that the population had increased 7 per cent. from 1831 to 1838, the average for each inhabitant, instead of being 5*s.* 4*d.*, will be 4*s.* 11½*d.*

The sum raised in this county for poor-rate, county-rate, and other local purposes, in 1833, was 30,616*l.*, levied upon the following descriptions of property:—

On land . .	£27,072
Dwelling-houses .	3,284
Mills, factories, &c. .	166
Manorial profits, navigation, &c.	93
Total	£30,616

Under the property tax Pembrokeshire was assessed, in 1815, at 220,291*l.*, namely, property from lands 181,057*l.*, houses 20,096*l.*, tithes 15,395*l.*, profit from manors 38*l.*, profits of quarries 603*l.*, profits of mines 3102*l.* The annual profits of trade were assessed at 43,102*l.*

The county expenditure for the year ending 25th March, 1838, amounted to 26,676*l.*, namely—

Relief and maintenance of the poor .	£21,576
Removal of paupers, law charges . .	527
Payment towards county-rate . .	3,306
Fees to clergymen and registrars under Registration Act	128
Outlay for register-offices, books, &c., under ditto	93
Payments under Parochial Assessments Act	68
For all other purposes	958
Total .	£26,676

There are three unions in Pembrokeshire, under the Poor Law Amendment Act, namely—

	No. of Parishes.	Population, 1831.	Expended for Relief of P[illegible] Before the Union.	Year end. 25th M[illegible] 18[illegible]
Haverfordwest	63	33,533	11,221*l.*	91[illegible]
Narberth .	51	21,902	5686	52[illegible]
Pembroke .	21	17,191	5842	56[illegible]

In 1835-6 the number of bastard children chargeable to the poor-rate in the county was 863, or one in 94 of the population, according to the census of 1831; the average for Wales being one in 139, and for England one in 215. At the same period 95 lunatics and idiots were chargeable to the poor-rate, or one in 857 of the population; the proportion for Wales being one in 807, and for England one in 1033.

The number of turnpike-trusts in the county in 1836 was four, having 173 miles of road under their charge. The income from tolls in 1835 was 1605*l.*, and the total income amounted to 2903*l.*, including 1008*l.*, borrowed on security of the tolls. The expenditure amounted to 32[illegible]*l.* The debts of the trustees were 19,273*l.*, consisting of 15,[illegible] bonded or mortgage debts; 3654*l.*, unpaid interest, and the remainder of the balance of small sums due to the treasurers.

The number of persons charged with criminal offences and committed, in the three septennial periods ending with 1820, 1827, and 1834, were 179, 150, and 178, making an average of 25 annually in the first period, 21 in the second, and 25 in the third. In each of the following years the numbers committed, convicted, and acquitted were respectively as follows:—

	1835.	1836.	1837.	[illegible]
Committed .	38	67	54	[illegible]
Convicted .	20	35	28	[illegible]
Acquitted .	18	32	26	[illegible]

Of the 46 persons committed in 1838 the number of ma[illegible] was 26, females 20; and 16 of the former and [illegible] of the latter were between 21 and 30 years of age; only [illegible] females, were under 16. There were 10 of the males [illegible] females who could neither read nor write; 13 males [illegible] females could read and write imperfectly; 3 males could read and write well; and the state of instruction of the remaining 3 was not ascertained. None of the alleged offences were of a heinous nature; 6 were offences against the person, 7 offences against property attended with violence, 27 offences against property unaccompanied by violence, 23 being cases of simple larceny, and the remaining 6 were other offences of a light character. Of the 20 persons convicted, 17 were imprisoned for various periods of six months and under; 2 for above six months and under one year; and 1 was transported for 15 years. Of the 26 acquitted, 17 were found not guilty on trial; in the case of 8 no bill was found; and in one case there was no prosecution.

The number of persons registered to vote for the county members, in 1834-5, was 3664; in 1835-6 there was an increase of 202, the number of persons qualified being 3866. In 1835 there were 1296 persons in the county qualified to serve on juries under 6 Geo. IV., c. 50.

There are only two savings'-banks in the county. The number of depositors and amount of deposits in each of the following years was as under:—

	1835.	1836.	1837.
Number of depositors .	1230	1362	1417
Amount of deposits .	41,827*l.*	45,107*l.*	48,047*l.*

Education.—According to the Charity Reports, the income of endowed schools in the county is 412*l.*, and the sum of 38*l.* is applicable to purposes of education in schools not endowed. The following summary is taken from the third volume of the Education Inquiry made in 1833 on the motion of the late Earl of Kerry:—

	Schools.	Scholars.	Total.
Infant schools	8		
Number of children at such schools; ages from 2 to 7 years:—			
Males . .		38	
Females . .		56	
Sex not specified .		131	
			225
Daily schools	193		
Number of children at such schools; ages from 4 to 14 years:—			
Males . .		1,874	
Females . .		1,387	
Sex not specified .		2,832	
			6,093
Schools . . .	201		
Total of children under daily instruction			6,318
Sunday-schools	145		
Number of children at such schools; ages from 4 to 15 years:—			
Males . .		2,693	
Females . .		2,584	
Sex not specified .		5,859	
			11,136

Eighteen Sunday-schools are returned from places where no other school exists, and the children who are instructed therein (1229 in number) cannot be supposed to attend any other school: at all other places Sunday-school children have opportunity of resorting to other schools also, but in what number, or in what proportion duplicate entry of the same children is thus produced, does not appear. Twelve schools, containing 719 children, which are both daily and Sunday-schools, are returned from various places, and duplicate entry is therefore known to have been thus far created. In some of the Sunday-schools, adults and aged persons as well as children attend; and two Sunday-schools are mentioned where some are said to attend at eighty years of age.

Maintenance of Schools.

Description of Schools.	By endowment.		By subscription.		By payments from scholars.		Subscrip. and payment from scholars	
	Schls.	Scholars.	Schls.	Scholars.	Schls.	Scholars.	Schls.	Scholars.
Infant Schools	—	—	—	—	7	214	1	11
Daily Schools	19	683	10	719	155	4,152	9	539
Sunday Schools	4	185	133	10,400	4	262	4	290
Total.....	23	868	143	11,119	166	4,627	14	840

The schools established by Dissenters, included in the above statement, are—

			Scholars.
Infant-schools .	2, containing		27
Daily-schools .	10	.	362
Sunday-schools .	91	.	7,736

The schools established since 1818 are—

Infant and other daily schools	104, containing		2,227
Sunday-schools .	115	.	9,241

Seven boarding-schools are included in the number of daily schools given above. All religious denominations, including the Established Church, disclaim the fact of education being confined in any of the schools in the county to children whose parents are members of their respective denominations.

Lending libraries of books are attached to 4 schools in this county.

PE'MPHIGUS is a disease of the skin, consisting of the eruption of one or more rather large blisters, containing serous fluid, and terminating either in thin scales, in superficial excoriations, or in ulceration. The common and most acute form of Pemphigus is usually preceded by shivering, and accompanied by slight feverishness; the eruption appears on some part of the body from one to four days after the beginning of the illness, with a pricking sensation and bright redness of the part affected. Within 24 hours afterwards the blisters begin to rise, and increase in size till they are most frequently as large as nuts, but often much larger, and sometimes smaller. They then, after two or three days, burst, and leave the skin raw and painful. A thin scab usually forms over the exposed skin, and after a few days more, drops off and leaves it healthy, but redder, and with a thinner cuticle than natural. The treatment should consist of gentle purgatives, and cooling medicines and diet; the local applications, if any, should be mild dressings, merely for the purpose of defending the raw surfaces from the air and injury. The disease will thus usually run its course to natural recovery.

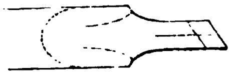
A more obstinate form is the chronic pemphigus, which occurs in old or very debilitated persons. The blisters appear one after the other, through an indefinite length of time, some breaking out while others are healing or ulcerating or even sloughing. They are so commonly the accompaniments of other more serious disorders, that the local affections of the skin in these cases are seldom the objects of peculiar treatment; if the condition of debility on which they are grafted can be relieved, they also will soon disappear.

A third form is that termed infantile or gangrenous pemphigus. It is entirely confined to children and especially affects those who are less than five years old. It occurs sometimes as an epidemic, and is very common among the children of the poor in Ireland, where it is known under the name of white blisters, burnt-holes, eating-hive, &c. The blisters in this form are usually succeeded by deep ulcers, which enlarge rapidly and discharge profusely, and have dark livid edges and a remarkable smell. The child at the same time becomes emaciated and weak, and often about the eighth day of the disease sinks into a state of debility which soon terminates fatally. All the usual modes of treatment being found useless, Dr. Stokes, by whom this form of the disease has been particularly described, sought out a remedy which had been commonly used with success by an empiric, and found it to be the juice of the great figwort (*Scrophularia nodosa*), which was made up into an ointment. He has since used it with considerable success. The swollen and ulcerating parts having been previously poulticed, the ointment should be melted, and applied over them very gently with a soft feather. This ointment is prepared by stirring the young leaves of the Scrophularia in a small quantity of unsalted butter till it acquires a full grass-green colour. It is of considerable utility in many diseases of the skin besides that for which it was first employed. In pemphigus its use should be combined with nutritious diet and tonics.

PEN. This simple but useful little instrument was formerly made of reed, but the quill has been used in this country for that purpose for about five hundred years.

Of the common method of making pens by hand it is not necessary to speak; we shall therefore only say a few words upon the manufacture of 'quill nibs.' The barrel of the quill in the first place has both ends cut off, and is divided down the centre; the halves are then laid on their convex side and the edges shaved smooth; after this they are divided into three or four lengths each, and the end of each length is made into a pen by a small machine, which at one stroke makes the slit and cuts the shoulders; they are then finished by being nibbed by hand. Small pocket machines may be bought at the cutler's for making pens on the same principle as that used in the manufacture of the nibs; but they are expensive, and require careful usage, or they soon get out of order.

The pen used for German text, old English, ingrossing, and other black hands, as they are called, is not generally known. It differs in make, but still more in application, from that employed for ordinary writing. The nib is made as broad as the thick or down stroke of the writing is intended to be, and in using it no pressure is required to open the nibs, as in making a thick stroke by the common pen. The only use of the slit is to give greater elasticity to the point, and to form a channel for the ink. For very large writing two other slits are sometimes made, one in each shoulder; a pen made in this manner works more freely, and does not tire the hand so much as if made with one slit only. The fine or up strokes are produced by throwing the pen to one of the angles of its nib, generally that to the left of the hand in writing, by a turn of the wrist, and a practised hand can produce in this manner the finest hair-stroke. These pens are made of the turkey quill, the goose quill being too weak for the purpose. In making the slit, in all quills, but more particularly in these, it is necessary that they should be well scraped, as the upper surface, being formed of fibres lying in rings around the quill, will otherwise cause the slit to be ragged. The shoulders of these engrossing pens should be well hollowed out, so that they may be nibbed several times without the necessity of mending the other parts of the pen. In nibbing them, a sloping cut, or false nib, must first be made, to reduce the substance of the quill, which would, if this were not done, be clumsy, and deliver the ink too fast. This remark applies also to the common quill, though in a smaller degree. The real nib must then be made perpendicular to the quill, and the knife held in such a manner as to take more off the right than the left side, as seen in the annexed figure, which represents the back of a pen fit for writing German-text letters an inch long. The object in sloping the nib is to render the pen more convenient for describing curves, &c., for by holding the elbow rather away from the side, as in drawing, the nib may be more easily brought to an angle of about 45 degrees with the line of writing, so as to be equally applicable to the horizontal and perpendicular position of the different parts of the letters. On account of this angular position of the nib, it is necessary to make it rather wider than the thick stroke of the writing.



Many attempts have been made to substitute steel or other pens for the turkey quill, which is short and of small diameter, but hitherto without success.

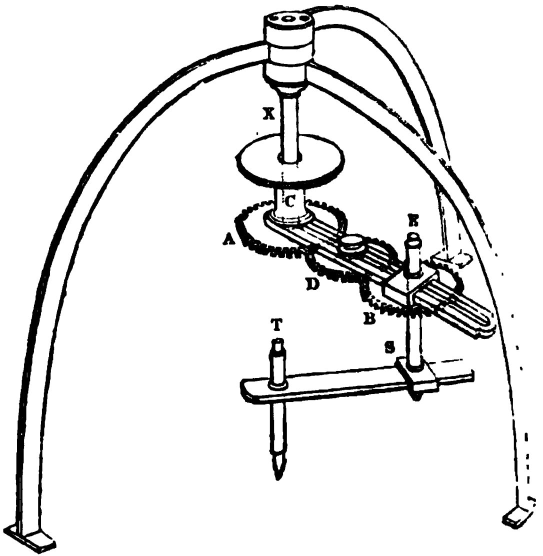
Steel Pens.—Owing to the constant necessity for mending quill pens, the loss of time consequent thereon, and the inequality of the writing, an immense amount of labour and ingenuity has been employed to produce some more durable substitute. The only substitute however which has attained to anything like general use is the steel pen. These pens are manufactured to an amount in quantity, and at a cost so small, as hardly to be credible. Different makers have different modes of operation, but the following will give a general idea of the method employed. In the first place flat pieces of steel are cut out, of the shape required, by a stamping-press; they are then placed under another press, which pierces the holes and cuts the slits; and they are struck into their convex shape by a third press. They are then polished and tempered. The polishing is managed in rather a curious manner; a quantity of pens are shut up in an iron cylinder, leaving a considerable space unoccupied; this cylinder is attached at each end to a crank, the axes of which are connected by a wheel and set in motion by a handle or by machinery. Thus by being rubbed against each other the pens come out well polished, and with all the burrs or sharp angles left by the cutting-presses rubbed smooth. Sometimes the steel of which these pens are made is alloyed with silver, platinum, rhodium, or other metals, which improves the elasticity, and in some cases prevents rust; but this alloy considerably increases the expense, and in the case of rhodium to an amount almost sufficient to prevent its use.

Ruby Pens.—Pens made of gold with a small ruby at each nib seem to be perfect, some having been used, to our knowledge, for years without needing to be repaired, but the price is so high as to prevent the possibility of their coming into general use.

Fountain Pen—is a pen made with a reservoir in its stem or holder, to supply ink for some time without replenishing. The nib is in most cases supplied by a small valve, which may be closed when not in use.

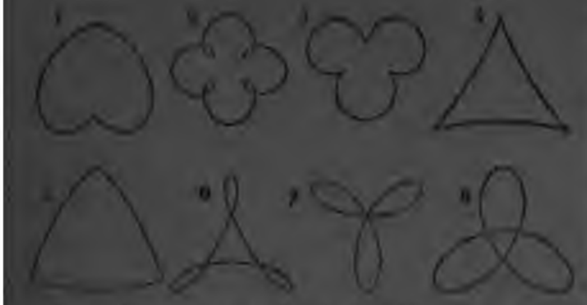
Music Pens.—There are two pens used for the purpose of writing music; the one to rule the lines, and the other to make the dots. The former is a piece of brass with five prongs or points, in each of which is a channel for the ink, which is supplied from a small cup in the solid part of the pen just above the division of the points. The latter is a mere tube with a hole in its side for supplying it with ink, and a small wire or piston fitted within it. The ink flows between the wire and its case, and the dot is made by placing the pen upon the spot, and pressing the wire down upon the paper.

Geometric Pen. This is an instrument invented by Suardi, an Italian, for drawing geometric curves. These curves may by combination be made to form an almost infinite variety of patterns. It is supported, as shown in the diagram, on three legs bowed so as to allow room for the instrument to work within them. These legs shut together by the joint at the top for the convenience of package. Attached to the joint is a stem or axis X, upon the lower end of which is fixed the toothed wheel A; this stem, with its wheel, is stationary, and all the other parts of the instrument move round it. Just above the wheel A is a small tube or cannon, to which is attached an arm carrying two boxes and spindles for supporting the wheels D B; the spindle E is continued downwards, and terminates in a socket S, through which passes an arm carrying the pencil or tracer T. The two wheel boxes D B on the one arm, and the socket S on the other, may be fixed at any part of their respective arms by means of screws for that purpose; fixed to the tube C is a small circular plate of metal with a milled edge, by which the instrument is moved around its axis by the thumb and finger.



The sort of curves produced by this instrument depends upon three circumstances: first, the relative size of the wheels A and B; second, whether the wheel D is employed or not, or in other words, whether the two arms move in directions contrary or similar to each other (this wheel has no effect otherwise, and may be of any convenient size); and third, on the relative distance of the tracer T from the spindle E, and of that spindle from the axis X, which may be expressed as the relative distance of T E and E X.

The following diagram gives an idea of a few of the most simple curves. The number of parts or leaves in each figure depends on the first of the three circumstances above mentioned: for *fig.* 1 the wheels A and B must be equal; for *fig.* 2, as 4 to 1; and for the rest, as 3 to 1. On the second circumstance depends whether the loops or parts



lie within the curve, as in *figs.* 1, 2, and 3; or on the outer side, as in the others; and lastly, upon the third circumstance depends the shape of the points or loops themselves. For the eight curves given above, T E must be less than E X, but if this is reversed, the curves assume a most curious, complicated, and sometimes beautiful arrangement.

Suardi states that 1273 curves may be produced by the changes of twelve wheels, the smallest having eight, the next sixteen, and so on to ninety-six teeth, and that by the addition of a few pieces, spirals with a circular base, and particularly the spiral of Archimedes, may be produced.

For further information the reader is referred to Suardi's work, entitled 'Nuovo Istromento per la Descrizione di diverse Curve Antichi e Moderne,' &c.; and to Adams's *Geometric Essays.*

PENÆUS. [Shrimps.]

PENALTY, in its original and proper sense, is a pecuniary punishment imposed by statute upon parties guilty of certain offences. This term is also used to denote a sum of money which a party to a contract has engaged to pay in case he violates his engagement. Penalties imposed by statute are strictly regulated by statute; but with respect to penalties created by contract, the rule is neither so strict nor so uniform. In one class of cases the courts of common law have the power of awarding damages commensurate to the injury sustained, though the parties have agreed that a fixed sum shall be paid by way of penalty. In a second class, the courts of common law possess this power of limiting the sum to be recovered by action to the amount of injury sustained, only where the plaintiff, by bringing an action of assumpsit or of covenant instead of an action of debt, abandons his claim to the penalty. In a third class, the actual amount of injury is capable of being ascertained, but the courts of common law are, from the form of the proceedings, absolutely bound by the contract of the parties. Here the courts of equity interpose to relieve the party from the rigorous exaction of the penalty. (Comyns's *Digest, Chancery* (2 Q 3—4 D 2.) In a fourth class, although the sum stipulated to be paid upon the doing or the omission of a particular act may be obviously disproportioned to the amount of injury sustained, yet if there be no means of ascertaining the amount, or if it be expressed in the contract that the sum to be paid shall be regarded not as a penalty, but as liquidated damages, that is, as the sum ascertained and agreed between the parties as the pecuniary amount of the injury, neither courts of law nor courts of equity can prevent the recovery of the stipulated sum. Where however a large sum is stipulated to be paid in the event of the non-payment of smaller sums at a particular time, no agreement between the parties can so far alter the real nature of the transaction as to convert this sum into liquidated damages. In other cases the distinction between a penalty and liquidated damages is often difficult to ascertain, and some of the decisions on this head are not easily reconciled.

The third class of cases, those in which the interference of a court of equity is necessary, is much narrowed by the statute 8 & 9 Will. III. c. 11, s. 8, under which, in actions in courts of record upon any bond or penal sum for the performance of covenants or agreements contained in any indenture, deed, or writing, the plaintiff is required to state the breaches of covenant or agreement which he has sustained, and damages are to be assessed accordingly. If the plaintiff recover in the action, judgment is entered up for the penalty, but execution issues only for the damages assessed by the jury upon the breaches stated and proved, the judgment remaining as a security against future breaches of the same covenant or agreement, or of other covenants or agreements contained in the same instrument and protected by the same penalty. [Bond; Damages.]

It was formerly usual to insert in leases a stipulation that if the rent were not paid on the day on which it became due, a small sum should be added for every day during which it remained unpaid. This graduated penalty is called a *nomine poenae*, and the landlord may distrain [Distress] for it. A *nomine poenae* is seldom found in modern leases, the interest of the landlord being considered sufficiently protected by a clause usually inserted, enabling the landlord to make the lease void in case of non-payment of rent or breach of other covenants.

PENANCE (in Latin, *Poenitentia*) is a censure or punishment, enjoined by the ecclesiastical law, for the purgation or correction of the soul of an offender, in consequence of some crime of spiritual cognizance committed by him. Thus a person convicted of adultery or incest was adjudged to do penance in the church or market, bare-legged and bare-headed, in a white sheet; and was required to make a public confession of his crime, and to express his contrition in a prescribed form of words. After a judgment of penance has been pronounced, the ecclesiastical courts may, upon application by the party, take off the penance, and exchange the spiritual censure for a sum of money to be paid and applied to pious uses. This exchange is called a commutation for penance; and the money agreed or enjoined to be paid upon such a commutation may be sued for in the ecclesiastical court.

The peine forte et dure imposed upon a person who stands mute on his trial at the common law is often inaccurately termed penance. [Peine Forte et Dure.]

PENANG, PULO (or Island of Penang), is the seat of government of the British possessions in the Strait of Malacca. These possessions consist of the Island of Penang, province Wellesley, the provinces of Tenasserim, Malacca, and Singapore. The three latter are noticed under separate heads.

The Island of Penang, also called Prince of Wales' Island, lies between 5° 15′ and 5° 30′ N. lat., and between 100° and 100° 5′ E. long., and extends from south to north about 16 miles, with an average breadth of eight miles, which gives a surface of nearly 130 square miles. This island consists of a mass of rocks, which occupy about two-thirds of the surface, and of two tracts of alluvial soil, which extend on the eastern and western side of the rocks. The western plain is mostly a swamp, and nearly uninhabited; but the eastern, which on an average is two miles wide, and opposite George Town more than four, is at present well cultivated and populous. The highest portion of the mountains occupies the middle of the island; where Mount Elvira, or Mount Macalister, rises to the elevation of 2560 feet, according to an estimate. Farther north is Flagstaff Hill, which is 2248 feet high, according to measurement. The hills which lie between this highest range and the eastern plain rise to the elevation of 600 to 800 feet. The mountains are covered with lofty trees, except their summits, which are naked for about 200 or 300 feet from the highest point downwards. Along the sea are swampy tracts covered with mangroves, and contiguous to them mud banks which frequently change their position and extent. From the belt of mangroves the country extends in gentle undulations to the foot of the hills, and has an indifferent soil, except where it is interrupted by deeper depressions containing an alluvial soil which yields good crops of rice. The narrow valleys which extend into the mountains have their slopes covered with a tolerably fertile but varying soil.

The province Wellesley lies opposite Pulo Penang on the Malay Peninsula, and is separated from the island by a strait, which at its southern extremity is nearly 10 miles wide, but grows narrower farther northward; opposite Fort Cornwallis it is hardly two miles wide. Province Wellesley extends from 5° 10′ to 5° 35′ N. lat., and lies between 100° 11′ and 100° 19′ E. long. It extends along the coast about 30 miles, and from 4 to 10 miles inland. On the east it borders on the kingdom of Keddah, or Queda, which is dependent on Siam, and the boundary on this line was regulated in 1831. The northern boundary-line is formed by the river Muda, which separates it from Keddah, and on the south it is separated by the river Krian from the state of Perak. The area is estimated at 160 square miles. The mountain-ranges, which in this part extend over the greatest part of the Malay Peninsula [Malay Peninsula], do not approach so near the sea as to enter the province, except near the river Juru (5° 20′ N. lat.), where one of their offsets terminates in the Mormajam, a hill 1569 feet high, the western slope of which lies within the English territory. The coast-line exhibits a narrow sandy belt of low land in the northern districts, and in the southern a broad mud flat covered with mangrove-trees and flooded at high-water. Behind the sandy belt and mangroves there are extensive alluvial tracts under rice cultivation, alternating with gentle swells of light soil running parallel to the coast. About four or five miles from the coast there are dry alluvial plains which stretch south and north. A few hills of moderate elevation are scattered over these plains. The soil of the alluvial plains and rice-grounds is superior in fertility to lands of the same classes on Penang, but that of the hills is much the same.

Rivers.—There are no permanent streams in the island of Penang, but several rivers traverse Wellesley province from east to west, rising in the elevated mountains in the state of Keddah. These rivers, enumerated from north to south, are Muda, Pry, Juru, and Krean. All these rivers have bars at their mouths, generally with seven to nine feet water on them: that of Pry river may be crossed at flood-tide by vessels of 300 tons burden at least. All these rivers are navigable for moderate sized vessels nearly the whole length of their course within the province. Between Muda and Pry rivers is the mouth of a creek, called Qualla Tulloh, which forms a good harbour for boats; and near it is an extensive village of the same name.

Climate.—The dry and wet seasons in these countries are not so distinctly marked as in other parts of the East Indies. What is properly called the rainy season is limited to three months, from September to November, but showers, and frequently heavy showers, occur in all the other months. Thus rain fell almost every day between October, 1789, and June, 1790; and between May, 1833, and April, 1834, both included, it rained 145 days on Penang plains, 166 days on the Flagstaff Hill, and 228 days in Province Wellesley. Droughts of considerable duration occur at intervals of four or five years, and still longer droughts at longer intervals. The quantity of rain from May, 1833, to April, 1834, both included, on Flagstaff Hill was 116·6 inches, on Penang plains 65·5 inches, and in province Wellesley 79 inches. The heat is not oppressive, and is greatest in June and July. A hot wind is not known within the straits. The highest temperature in George Town is 90° and the lowest 70½° Fahr. The mean annual temperature on Penang Hill is 71°, on the plain 79⅔°, of the mornings 75⅔°, from mid-day to 4 o'clock 83⅔°, of the evenings after sun-set 80°. The average monthly range of the thermometer is 11° and the greatest monthly range only 13°. The northern half of Wellesley province has the more healthy climate, as it enjoys the advantages of a regular change of sea and land breezes. The rainy season is considered the spring, and January, February, and March as the autumn; in the former period the rice is sown, and in the latter it is harvested.

Productions.—Penang derives its importance partly from the cultivation of spices. Pepper has for many years been the object of an extensive cultivation, but the low prices of this article have of late years checked this branch of agriculture. Previous to 1807 the average annual quantity was nearly four millions of pounds, but it decreased rapidly, and at present it does not exceed 2000 peculs, or 856,000 pounds weight. It has been replaced by the cultivation of clove and nutmeg trees. Several attempts have been made by the French and English to transplant these trees from the Moluccas to several parts of America, Africa, and India, but none of these attempts seem to have been completely successful, except those made at Bencoolen on Sumatra and on the Island of Penang, and this branch of agriculture is rapidly increasing. Captain Low in 1835 estimated the number of nutmeg-trees in 30 plantations, at 80,000, and he says that about 45,000 of them were bearing, and their annual produce was 130,000lbs.; the number of clove-trees is still greater, and increasing. The mace and cloves grown in Penang are considered the finest in the world, and preferable to those imported from Banda and Amboyna, the mace being more substantial and flaky, and the cloves more full and richer in colour. The nutmegs also are thought not to be inferior. Since palm-oil has been extensively used in the manufacture of candles in England, the plantations of cocoa-nut trees have greatly increased, and oil is made by the Chinese settlers in the country to a great extent; the nuts themselves are exported to Singapore, the Tenasserim coast, and Rangoon. The sugar-cane is partially cultivated on Penang, but extensively in Province Wellesley, especially in the central and southern districts, where the sugar plantations occupy about 900 acres of land; they are in the hands of the Chinese settlers. These people also cultivate three different plants, from which they make indigo, but the product is too crude for the European market. The leaves of a plant, called *nilam* by the Malays, are occasionally exported in considerable quantities by Arab traders, who use them as stuffing for mattresses and pillows; in Siam they are used for making perfumery. Tobacco, coffee, and cotton are only raised for consumption. A considerable quantity of betel is exported to the neighbouring state of Keddah. The areca-nut, whence the island derives its name (Areca-nut Island), is not much attended to at present, though its cultivation constituted the chief occupation of the Malays, who first occupied the island. All the areca raised on the east coast of Sumatra is brought to Penang, and hence exported to other parts of Asia.

Rice and Indian corn are the only kinds of grain cultivated. Rice-land in Penang yields on an average about 75 fold, but in Wellesley Province more than 100 fold. As Indian corn is considered by the Malays far inferior to rice as food, its cultivation is not extensive. The plantains and bananas are, next to rice, the principal objects of agriculture, and in times of scarcity supply in some measure the place of grain. Eight varieties are raised.

No country on the surface of the globe possesses a greater variety of fruit-trees than the Malay Peninsula and the Indian Archipelago. The fruit-trees which are cultivated are the mangosteen, durian, jack-tree, champadah, a species of jack, rambei, rambutan, the Siam mango, the egg mango, machang, jamboo kling and jamboo ayer mawah, num num (cynometra cauliflora), lime, custard-apple, mulberry, pine-apple, the grape, and orange. Many other fruit-trees are found in a wild state in the forests on the declivities of Mount Moratajam, and their fruits are brought to the coast. Capt. Low mentions twenty-three different kinds of fruit brought from the skirts of Mount Moratajam to Penang.

The same author gives a list of 128 different kinds of trees met with in the forests of the country, and applicable to building and other domestic uses. Boat-building is a favourite occupation with the Malays, and they build good boats. Oil is extracted from the fruits of several trees, both for burning and for culinary purposes. The bark of other trees is used for tanning leather and for fish-lines. The India-rubber tree grows along the western boundary of Province Wellesley. Dammer, or the resin of the dammer-tree, is collected and used for paying vessels. Minyak dammer, or wood-oil, is the sap of another tree, and employed in careening ships. There are also twenty-two species of ratans, one of which produces dragon's blood; and twenty different kinds of bamboos, which are used for domestic purposes. The wood or bark of some other trees is used in dyeing. A kind of cardamum is collected in the forests beyond the eastern frontier, and exported by the Chinese.

Besides the native vegetables, which are numerous, the Chinese cultivate cabbages, celery, and lettuce. Peas and carrots thrive well, but potatoes have not succeeded. There are however many varieties of sweet potato, one of which is much esteemed. Yams, both red and white, and French beans, are extensively grown.

Buffaloes and cattle are rather numerous. The cattle are reared for the dairy, the cattle for slaughter being chiefly imported from Keddah and Patani. The black buffalo is most prized, both for draft and slaughter. The annual consumption of cattle on Penang and by the shipping is about 300 head. About 400 buffaloes are slaughtered yearly. Goats and sheep do not abound, but a great number of hogs are reared by the Chinese. Poultry is plentiful, especially in Province Wellesley, whence upwards of 120,000 are annually sent to Penang. A great number of ducks are reared, and their salted eggs form an article of provision for native prahms and Chinese junks.

Wild animals of the larger size are found in Wellesley Province, as the elephant, rhinoceros, and tiger. The elephants are sometimes exported to Madras, and used in the neighbouring states to carry the tin from the mines to the coast. They are also killed by the Malays for the sake of the ivory. The rhinoceros is killed for its horn and hide. There are two species of wild ox, and abundance of wild hogs and deer, especially in the forests of the province, where also the plandok, a hornless deer about the size of a hare, occurs in great numbers. There are also several kinds of monkeys.

Birds are found in great variety, and many of them have great beauty. The catching and preserving of the skins with the feathers on, of the larger kinds of kingfishers, is a lucrative employment of the natives. These skins are exported to China, where they are used for embroidering dresses. The other birds most distinguished by the beauty of their feathers are, the pagar, which has a brownish crimson plumage, and is rather larger than a moor-fowl; the large kwang, or Argus pheasant, and the smaller sort, which has its back spangled with eyes; and the murragh, or the peacock, which has a magnificent plumage of a light golden hue.

Penang is cheaply and plentifully supplied with fish. Besides the porpoise and skate, Low has enumerated fourteen species of fish which are considered as poisonous or unwholesome, and fifty others which are eaten. A small species of whale frequents the strait between Penang and the province at intervals. Fishing-stakes afford nearly exclusive employment to numbers of Chinese and Malays. There are eighteen species of crabs, oysters, and other shell-fish. A species of sea-turtle, the hog-billed, is frequent in some places, and another smaller kind in the rivers: the eggs of both species are eagerly sought after

Gold, which is found in nearly all the states of the Malay Peninsula, does not occur within Wellesley Province. Tin was some years ago discovered to exist in some places, but in too small a quantity to be worked.

Inhabitants and Population.—When the English took possession of Penang Island (1786), they found only a few Malay families, mostly fishermen; but natives from the neighbouring countries, as well as Chinese, and Chuliahs from Hindustan, soon flocked to it, and the population, in 1835, consisted of ten different nations.

Population of the Island of Penang.

Fixed:—	
Europeans and their descendents	790
Armenians . . .	21
Malays	16,435
Achinese (Sumatra) . .	350
Battas (Sumatra) . .	561
Chinese . . .	8,751
Chuliahs . . .	7,886
Bengalese . . .	1,322
Siamese and Burmans . .	648
Arabs . . .	142
Parsees . . .	50
Native Christians . .	708
Caffres . . .	180
	37,844
Fluctuating:—	
Native military and followers, averaged at . . .	700
Convicts (from Hindustan) .	1,263
Itinerants . . .	400
	2,363
Total .	40,207

When the British acquired the coast-line called Wellesley Province, it was very thinly inhabited; and though the population gradually increased, it did not exceed 5000 inhabitants in 1821. But in this year the raja of Ligor invaded the neighbouring state of Keddah, and took possession of it for the king of Siam. Upon this a great part of the Malay population abandoned Keddah, put themselves under the protection of the British, and settled in Wellesley Province. In 1835 the population of this country consisted of—

Malays . . .	42,500
Chinese . .	2,252
Chuliahs . .	549
Bengalese . .	579
Siamese . .	500
Fluctuating . .	500
	46,880

Thus the population of this province has doubled ninefold in fifteen years. It contains 293 persons on a square mile, and the island 310 persons.

George Town is built on the eastern side of the Island of Penang, where it projects into the strait, and contains a population of 20,000, mostly Chinese. It is the seat of the governor of the British possession on the Strait of Malacca, and carries on a considerable commerce. The harbour, which lies on the south-east of the town, is well sheltered, and may be entered by any kind of vessels from the north; but vessels drawing more than 18 feet of water cannot sail through the strait southward. It is visited by most of the vessels sailing from Hindustan to China, and likewise by vessels from China, Arabia, and Siam. There are sometimes 300 vessels in the harbour. Since the foundation of Singapore, it has ceased to receive the commercial productions of the Indian Archipelago and the southern countries of the Malay Peninsula; but it is still the principal place to which the inhabitants of the eastern coast of Sumatra and the countries north of Malacca bring their goods. These goods consist of pepper, benzoin, camphor, gold-dust, areca-nuts, rice, ratans, sago, brimstone, tin, arrack, sugar, oil, tobacco, birds'-nests, trepang, and ivory. In 1825 the value of the exports of this place was estimated to amount to nearly 1,000,000*l.*, and probably it is not less at present. It exports to the eastern coast of Sumatra and the Malay countries north of Malacca, various kinds of piece-goods from England, Bengal, and Coromandel; cotton, opium, iron, steel; European coarse blue, red, and green cloth, and coarse cutlery. James Town is a small but thriving place, about a mile from the sea on the eastern plain of Penang Island, in a very fertile district. There are no towns in Wellesley Province; but in the northern more fertile and better cultivated districts, in some places, the higher parts of the low ridges are covered by continual rows of houses for several miles. The most extensive of these villages is Pinaga.

History.—Before 1786 the island and province belonged to the small kingdom of Keddah. In the war between the English and French, which terminated in 1783, the want of a good harbour in the southern part of the Gulf of Bengal was much felt by the British, and in 1786 they became desirous to acquire one on the eastern shores, as the coast of Coromandel does not offer such a place. The Island of Penang was found fit for that purpose, and it happened to be the property of an Englishman, Capt. Francis Light, of a country ship, who had received it from the king of Keddah as a marriage portion with his daughter. Capt. Light transferred his property to the East India Company, and was appointed first governor of the island. It was at the same time agreed to pay 6000 Spanish dollars annually to the king of Keddah in consideration of his ceding the sovereignty of the island. The British flag was hoisted on the 7th July, 1786. When the harbour began to be frequented by numerous vessels, great inconvenience and frequently loss were experienced, especially by the native merchants, from the piratical vessels which infested the strait and took refuge in the rivers which enter the sea opposite the island. The Company was accordingly desirous to get possession of this coast also, and as it then was nearly uninhabited, the object was attained by increasing the annual payment to the king of Keddah to 10,000 Spanish dollars. This country, which then contained only 1500 inhabitants, including a very few Chinese, was then termed Point Wellesley, which, not being a very correct designation for a line of coast, was subsequently changed to Province Wellesley.

(Crawfurd's *Journal of an Embassy to the Court of Siam and Cochin China;* Finlayson's *Account of the Mission to Siam and Hue;* Ward's *Short Sketch of the Geology of Pulo Penang,* in 'Asiatic Researches,' vol. xviii.; and Capt. Low's *Dissertation on the Soil and Agriculture of Pulo Penang and Province Wellesley,* Singapore, 1836.)

PENATES were Roman deities who were supposed to preside over families and houses. Cicero (*De Nat. Deor.*, ii. 27) derives the word either from *penus*, 'food,' or *penitus*, 'innermost;' but it appears probable that the latter etymology is the more correct. We learn from Festus (*Penus*) that the inner part of the temple of Vesta was called Penus, which seems to be connected with *penates*, *penetrare*, and *penetralia*. The hearth of the atrium was sacred to the Penates; and as this place was the innermost or most important part of the house, it was called the Penetralia. There appears sometimes to have been a kind of recess in the wall, called *sacrarium*, in which the images of the Penates were kept. (Cic. *in Verr.*, iv. 2; *Dig.*, i., tit. 8,

s. 9.) Every master of a family was the priest to the Penates of his own house.

It is a matter of some difficulty to determine who the Penates were; but there is no reason for believing that they were the same in every family. Some writers have thought the Lares and Penates to be the same, and it would appear that the Lares were included among the Penates. The Lares however were of human origin, and appear to have been regarded by the Romans as the manes of their ancestors [LARES]; while among the Penates we find mention of the superior gods, as Vesta and Jupiter. (Festus, s. v. *Herceus.*)

There were also public Penates, who were supposed to have been brought by Æneas from Troy. They were represented as two young men with spears in their hands, and the temple or chapel in which they were worshipped was not far from the temple of Vesta. (Dionys., i. 68; Cic., *De Nat. Deor.*, ii. 27; Liv., xlv. 16.)

The modern Genoese retain the custom of keeping household gods like the antient Romans. There is no house without its Lararium, and the Penates are conspicuous in every shop, indeed perhaps more so than in any other part of Italy. (*Communication from Genoa*, 1839.)

(Hartung, *Die Religion der Römer*, p. 71-81.)

PENCIL, the name given to the small brushes used by artists, whether made of hog's bristles, camel hair, fitch, or sable. The larger brushes are sometimes set in a tin tube, and the smaller in quills of different sizes. The hairs of a well-made brush should, when wetted, terminate in a fine point.

The well-known black-lead pencil is made by cutting 'Cumberland lead,' or plumbago, into thin plates with a saw, and again into strips as wide as the plate is thick. These strips are then laid in a groove in a piece of cedar, upon which is glued another and thinner piece: the whole is afterwards rounded by a plane adapted to that purpose. Pencils are commonly marked with certain letters to denote the quality of the lead, as H for hard, B for black, M for medium, and so on.

Other pencils are made of black and coloured chalks for drawing, and are much more convenient than the port-crayon.

The ever-pointed pencil is an instrument so simple and so well known as to require little description. The point, or nozzle, is made hollow to receive a small cylindrical piece of black-lead, about three-quarters of an inch long, which cannot pass through the lower end without some little force. Within the case is a screw or worm, which, if the case be turned round by one hand while the point of the pencil is held by the other, causes a wire or mandril, about the same size as the lead, to advance or retire. When a fresh lead is put into the point, the case must be turned round towards the left until the mandril is drawn up as far as possible. The point containing the lead is then to be screwed on to the case; and the case being turned gently to the right hand, the lead must be forced forward until it can just be seen at the point. These leads are made of different degrees and sizes, and the cases are marked accordingly. The leads are manufactured in the following manner:—After the plumbago is cut into square strips of the same diameter as, or a little greater than, the lead required, they are passed successively through three ruby holes, each smaller than the preceding. By this means they are rendered perfectly round and smooth, so as to offer no impediment to the working of the pencil. Most cases are made with a reservoir at the top, in which a supply of five or six leads may be carried.

PENCIL, a term of optics, and sometimes of geometry. A pencil of rays is a collection of rays which converge to or diverge from the same point; and a pencil of lines is a number of lines which meet in one point.

PENDENNIS CASTLE. [FALMOUTH.]

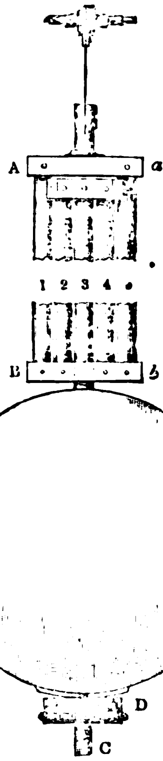
PENDENT, or PENDANT, in Gothic architecture, an ornamental mass of stone, hanging down or descending from the intersections of a groined vaulting. Pendents, no doubt, originated in bosses, of which they may be considered an enlargement, and may be described as being of a corbel or bracket shape. They are almost peculiar to the later florid English or Tudor style, in roofs of fan-work tracery, of which they are highly beautiful features, admitting of great variety of design. The roofs of King's College Chapel, Cambridge, St. George's, Windsor, and Henry VII.'s Chapel are fine examples of the effect of pendents. Carved pendents of a different kind were frequently employed for the enrichment of timber-roofs, but are not similarly applied, being suspended, not from the centre of the roof, but at the extremities of the hammer-beams, from which the ribs of wood-work forming the arches of the roof spring. Of this kind is the roof of the hall of Eltham Palace.

PENDENTIVE, though often inaccurately used as synonymous with pendent, has quite a different meaning, of which however hardly any explanation is to be met with in any English architectural works, nor is it indeed very easy to describe the thing itself intelligibly without the aid of drawings. Strictly speaking, pendentives are the spandrels or triangular spaces between the arches or arch-headed walls, as the case may be, supporting a dome, which is continued down to the springing of such arches; consequently where the dome rises from the cornice of a cylinder of the same diameter (as in the Pantheon at Rome), there are no pendentives, although there may happen to be arches in the cylindrical or polygonal circumference beneath the cornice. In such case the spandrels, or spaces between the arches are very improperly called pendentives, notwithstanding that they sometimes are so, pendentives being those portions of the inner surface of a dome where the latter is intersected by vertical planes, whether produced by voids or solids. The dome of the hall or principal office of the London and Westminster bank is a pendentive one.

PE'NDULUM, *Clock and Compensated.* The sensible equality of the oscillations of a weight suspended by a string or wire was first applied as a regulator to a clock by Huyghens about 1657. The successive improvements in the escapement, which sustains the motion of the pendulum and records its vibrations, and those in the pendulum itself, which secure a perfect equality in the duration of each oscillation, have finally produced the astronomical clock, the most accurate machine which man has hitherto constructed, and one of the most essential instruments in a modern observatory. For the construction of a clock and of its escapement, see HOROLOGY. We shall suppose that the dead-beat, or Graham's escapement, is that adopted, as it is undoubtedly the best of those yet discovered. The pendulum attached to ordinary clocks requires no description. The way in which motion is communicated to it is as follows:—The pallets PQ ['Dead-Beat Escapement,' HOROLOGY, p. 302] have motion on an arbor which passes through *p*, and has its pivots resting in holes in the clock-frame. A slender bar or wire, called the *crutch*, is attached to this arbor, and a notched piece projecting forwards and backwards from the crutch clasps the rod of the pendulum. The pendulum is hung from a cock at the back of the frame, and moves with the crutch. The clasp of the pendulum by the crutch should neither be very tight nor very loose, and the axis of motion of the pendulum should be exactly in the continuation of the arbor of the crutch. The clock-frame itself must be firmly fixed, as any shake or looseness of the support of the pendulum will alter its time of oscillation: the bob should be heavy and the arc of vibration small; and when good performance is required, the rod should be of deal, well varnished or oiled. Iron-wire makes the next best rod, and brass the worst. Whenever a brass rod is used for an ordinary clock pendulum, the maker is not master of his craft, or thinks little of his customer's knowledge. The errors arising from changes of temperature when deal, steel-wire, and brass are used are as 1, 3, and 5. It must however be remembered, that unless the deal rod pendulum be coated over, so as to be impervious to moisture, it will be liable to small errors arising from that cause. A range of 50° will not alter the rate of a clock with a white deal pendulum more than 5s a day, if Capt. Kater's value of the expansion of deal be correct.

In a well-made clock, the error arising from expansion from temperature is the most considerable, and is that which is to be guarded against. Before explaining more accurate and costly contrivances, it will be well to point out one recommended by Mr. Francis Baily. (*Mem. Astron. Soc.*, [illegible] p. 381.) Take a cylinder of lead about 14 inches long, pierced through its axis, as a bead, with a hole large enough to admit freely the rod of a wooden pendulum. This lead cylinder rests on a nut which works on a screw in the continuation of the rod below. The rod itself, from the centre of motion to the nut, will be about 46·0 inches. As it is easier to cut the cylinder shorter than to lengthen it, and as the expansion of the spring is not allowed for, and that of the wood is somewhat uncertain, it will be better to make the leaden cylinder an inch longer for a first trial; but even if the pendulum should turn out to be *under* compensated, an additional ring of lead may be added, above or below, of the thickness required. A lenticular form may be given to the weight, provided the proper length be preserved, and this will be an improvement, as it diminishes the resistance of the air, and the error which arises from the inertia of the air carried by the pendulum.

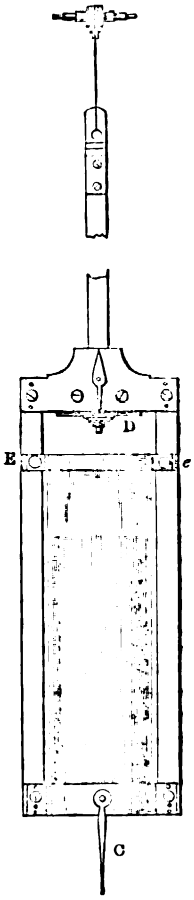
To the best clocks, either the gridiron pendulum of Harrison is applied (which was once chiefly used in England, and is still in repute abroad), or the mercurial pendulum of Graham, which is now employed by most makers in this country.



Gridiron Pendulum.

The above figure is not exactly the pendulum as composed by Harrison, but according to his principle. The *steel* rods 1 and 5 are pinned into two brass cross-pieces, A*a*, B*b*. The *zinc* rods 2 and 4 are pinned below into B*b*, and carry a cross-piece above, into which the *steel* rod 3 is pinned. Rod 3 passes *freely* through a round hole in B*b* (this is shown by dotted lines), and is tapped into a screw below; the bob rests upon the nut, which works on the screw. The steel rods 1 and 5 expand downwards, the zinc rods 2 and 4 expand upwards, and the steel rod 3 downwards; and it is possible so to adjust their lengths (the expansion of zinc being *more* than double that of steel) that the effects of the expansion downwards and upwards shall have no effect on the length of the pendulum or time of oscillation.

Harrison used brass instead of zinc for the upward expansion; and in order to produce a perfect compensation, was forced to use four more rods, a second pair of brass to expand upwards, and another pair of steel to expand downwards: nine in all. The foreign artists use zinc, which requires only five bars, less workmanship, and only one nice fitting. Zinc is objectionable as being a weak metal, and it is said by some persons to expand by jumps, which seems not very probable unless much exposed. The great objection to the gridiron pendulum is that the astronomer, if he be no workman, must rely upon the artist for perfect compensation (and this is perhaps never achieved); and again, if from rust or bad fitting the slipping parts should bind, the action will necessarily be by bounds and irregular. After the clock-maker has done his best, a year's experience will point out the error in the compensation, which can be easily remedied, if the fault be over-compensation, by cutting the zinc rods shorter. All the fixed parts should then be secured as firmly as possible by steady pins, as any attempt to reserve a power of further adjustment would be too dearly purchased by a ricketty frame. One or two flat brass horizontal bands are attached to 1 and 5 to keep the zinc rods in their places. These bands should not squeeze the zinc, and but just press against them with the spring of the metal. (Harrison is said, by Short (*Phil. Trans.*, vol. 47, p. 517), to have invented his pendulum about 1725.)



Mercurial Pendulum.

In Graham's pendulum, a glass jar, partly filled with mercury, is supported in a sort of steel stirrup. The pendulum rod passes through the top of the stirrup, and is held by a nut and adjusting screw at D. The height of the mercury in the jar is about 6·7 inches; but this will vary somewhat with the diameter of the jar, the substance of the rod and frame, and perhaps the variable expansion of the steel rod. The compensation can be altered, and finally perfected, by the astronomer. This quality, and the absence of any nice fitting or slipping parts, give Graham's construction a very decided superiority over Harrison's, especially for a clock which is not to be moved from place to place. These mercurial pendulums are generally constructed in a more expensive manner than is necessary. The vertical rods may all be made of stout steel wire, and the base and top of the stirrup of brass. Mr. Baily, in his valuable memoir above referred to, very justly recommends that the thread of the regulating screw should be deeper and coarser than it is usually made, and be tapped on a stouter cylinder. Graham's pendulum is described by himself. (*Phil. Trans.*, vol. 34, p. 40.) It was invented in 1722. There are many ways of compensating a pendulum for the effects of temperature, some of which are very ingenious, and others very simple. Those above described will suffice for an explanation of the principle; they are the most usual, the most easy of execution, and most exact in their operation.

If an escapement could be contrived which gave its impulse to the pendulum at the middle point of its vibration, and was wholly *detached* from it at all other times, such an escapement would be perfect; and escapements are almost to be considered good or bad as they approach this character. But in those which at present exist, time and dirt and thickening of the oil not only affect the amount of the impulse, which is comparatively of slight moment, but the continuing action of the teeth on the pallets is also irregular. The space through which the pendulum swings, or *arc of vibration*, is thus liable to variation, which again produces a change in the time in which each oscillation is performed, that is, if the pendulum be supposed to oscillate round a fixed axis. This inequality was more apparent in the early clocks, where the pendulum was light and the arc of vibration very large, than in those of modern construction, where the pendulum is heavy and the arc small. Huyghens proposed a most ingenious remedy, viz. that the upper part of the pendulum, which he made of two parallel strings, should wrap and unwrap on two cheeks, which, being shaped as cycloids, caused the bob itself to describe a cycloid. Now it is a property of this curve that all arcs are described in the same time, so that Huyghens's construction was a perfect remedy of the error mentioned. It is said by all later writers on the subject that the remedy is worse than the disease; and it is possible enough that something like sticking between the flexible top and the cycloidal cheek may take place at the critical point, *i.e.* just when the pendulum has arrived at the end of its swing, and is pausing for its return; and that there may be a difficulty in making and setting the cheeks so truly as to act on the pendulum in every part of its swing. A second objection alleged against Huyghens's cheeks—that, as the pendulum cannot be considered to be a heavy point suspended by a rod without weight, the centre of oscillation shifts *downwards* as the flexible portion of the top wraps on the cheek—might be easily got over by making the cheeks not truly cycloidal, but of such a form that the centre of oscillation of the compound pendulum shall oscillate in a cycloid, which would be easy enough when the form of the pendulum was given. In truth this is a matter of mere speculation in astronomical clocks, for there is a much easier way of producing sensible isochronism in them, which we will describe; but we suspect that the cycloidal cheeks might still be used advantageously in clocks which resemble Huyghens's, as the Dutch clocks which are in common use.

Instead of suspending the pendulum by a perfectly flexible string, or on a knife-edge, when the motion must be in a circle, the top of the rod ends in a flat spring. (See the foregoing figures, where the spring is seen in front, like a fine line, at the top of each pendulum.) This produces two effects upon the time of oscillation: first, by retarding the motion of the pendulum in its rise and accelerating its fall, the spring shortens the time of vibration, and the more the stronger it is; but as its action at each point is nearly proportional to the degree in which it is bent, that is, as the arc of vibration reckoned from the position of rest, this action will have no tendency to alter the isochronism of unequal arcs. The bending of the spring has however a second effect, that of causing the bob of the pendulum to describe a curve which is not circular, but which falls within a circle; and this, by proportioning the strength of the spring to the weight of the pendulum, may be made to approach to Huyghens's cycloid, or to that modification of it which we have described. It is possible to select a spring of such strength as shall completely satisfy this condition, at least within the necessary limits, that is, for such variations in the moving power as arise from dirt, thickened oil, and wear in the works.

Mr. Frodsham has lately published the *results of experiments on the vibrations of pendulums with different suspending springs*, which are deserving of attention. He found that a spring of a particular strength rendered the oscillations of a pendulum of a certain weight isochronous, and that a considerable alteration in the length of the spring did not affect this quality of isochronism. This we should explain by supposing the lower part of the spring not to have acted when it was longest, but to have always preserved its rectilinear form. In no case does Mr. Frodsham seem to have found a spring which caused the clock to *gain* in the larger arcs, which, on the information of other makers, and on theoretical grounds, we consider possible. With a spring stiffer than that which was isochronous, Mr. Frodsham found that using as effective lengths 0·97, 0·66, and 0·50 of an inch, the change of rate produced by using 4lb. 1oz. as the weight, instead of 2lb. 2oz., was to give the clock a losing rate of $3{\cdot}7^{s}$, $2{\cdot}6^{s}$, and $3{\cdot}5^{s}$ respectively. The law is not apparent, and it would seem that, even with this spring, shortening the spring had no sensible effect. Another remark of Mr. Frodsham's, which is very valuable if it is confirmed by extended trials, is, that the spring which produces isochronism is also the spring with which the pendulum, unattached to any clock, will keep up its motion for the longest time. It seems to us probable that this latter quality will belong to the weakest spring which preserves its full elasticity under the pull of the bob; for if the elasticity were perfect, the only cause of loss of motion would be the resistance of the air, which is not sensibly altered by the effect of the spring. However this may be, the subject is well worth further consideration. Notwithstanding the care bestowed by Mr. Frodsham, it is difficult to conduct inquiries of such nicety with an uncompensated pendulum. It will also be necessary, as we shall now point out, to attend to the state of the barometer when the experiments are in progress. For when the effect of the air upon the time of oscillation of a pendulum is examined, it will be found that the *resistance* of the air has no influence except the indirect one of shortening the arc of vibration, that is, of tending to make the clock gain, if the bob move in a circular arc. The *buoyancy* of the air acts more immediately, for it diminishes the *weight* of the pendulum, and leaves the *inertia* unaltered, and therefore diminishes the accelerating force. Hence a greater density in the air acts as a diminution in the force of gravity, *i.e.* makes the clock go slower. The effect is greater indeed than was at one time anticipated; for, as was remarked by Du Buat fifty years ago, and as has been recently shown by Bessel, the pendulum must be considered to include in its inertia a small wrapper of air which is involved in it or accompanies it in its course. (See a very elaborate and valuable memoir by Mr. Baily 'On the Correction of a Pendulum for the Reduction to a Vacuum,' *Phil. Trans.*, 1832, p. 399.) This latter portion of the effect of the air depends on the form of the pendulum and possibly may even be affected by the polish of its surface. Now the density of the air is proportional *directly* to the pressure of the atmosphere shown by the barometer, and *inversely* to the temperature, which is known from the thermometer. The latter portion might be practically included in the general compensation for temperature, but the former requires either a specific and peculiar compensation, or may be determined as a residual quantity, and tabulated for each clock with the mean height of the barometer for the period required. There is an investigation of the effect of atmospheric pressure on the rate of a transit clock at the Armagh observatory, in the *Mem. Ast. Soc.*, vol. v., p. 125. The author, Dr. Robinson, assumes that the variations of a clock from a constant rate are expressed by the sum of two terms, one depending on the temperature, the other on the pressure of the atmosphere shown by the barometer. The isochronism of the spring is supposed, or that the effect of any change in the arc depending on the above two causes is already expressed in the terms. When the error in the compensation for temperature is determined, this can readily be rectified by altering the quantity of mercury in the jar. The compensation for the variation of atmospheric pressure was made by attaching small barometers to the pendulum rod, but we believe this ingenious idea was not attended with any practical benefit. It would perhaps be possible so to balance some of these contending principles as to obtain a performance nearly perfect; thus an arc of vibration might be selected in which the increased density of the air, by reducing the arc, might accelerate the time of an oscillation as much as the increased buoyancy and inertia would retard it, or so nearly so, that the remaining difference might be completely annihilated by a proper selection of the pendulum spring. But even if this should be effected, and we see no obstacle to it except the time and trouble it would require, a change of the moving power, or of the action of the escapement, would alter the arc and derange the equilibrium. As the effect of time is generally to produce a falling off in the arc, a small addition to the clock weight might be made from time to time, so as to bring back the pendulum to its primitive arc, until the clock is cleaned, and its action restored that way. We shall conclude this long disquisition (which we propose for consideration until decisive experiments are made) by a piece of advice which we can warrant. Where the clock is much exposed to variations of temperature, enclose it in a second covering or closet. This will protect it from injury, and moreover will very much regularise the rude transitions of temperature to which clocks are in this climate liable. It is not improbable that the parts of a clock, and of its pendulum, if much exposed, may take their temperature at different times, and if so, the compensating principle is not brought into action, the clock must act irregularly.

It has already been said that a clock, to go steadily, should be securely fixed. The common mode is to fasten the case by strong bolts, under the rising board and again also as low as the pendulum bob, to a stone pillar or through a wall. The pendulum is generally suspended from a cock on the back of the frame, but it may be supported on a triangle standing on the rising board, or even to the back of the case, but there is then a fear that the axis of motion may not be in the axis of the pallets, or may not keep so. The clock being fixed, the first step is to put it *into beat*, *i.e.* to make the beats follow at equal intervals. The clock-maker does this in common clocks by bending the crutch, but when the discrepancy is not great, any one may produce the desired equality by tilting the frame a little; in table clocks there are generally footscrews for the purpose, or if not, the feet may be propped by pieces of wood, card, &c. In astronomical clocks, the angle which the crutch makes with the pallets admits of a small adjustment by two screws, which act on opposite sides of the crutch, and the operation is performed as follows:—Make the beats nearly correct by ear, and by touching the screws note which screw belongs to the longer leg. Then by softly deadening the pendulum as it rises, make it just not escape on one side. By very gentle pushes cause it to escape on that side, and see whether it escapes on the other; if it does not, one screw must be screwed up and the other released. After a few trials and errors it will be found that when the pendulum just escapes on either side, it will just escape on the other, and if there be a very small inequality indeed, a little tightening of one of the crutch screws will complete the adjustment. The pendulum should then be brought to rest, and the zero of the plate on which the arc of vibration is read off, be fixed just behind the pointer of the pendulum, shown at C.

To bring a clock to time, first make it nearly right by the adjusting screw D, but let it have a losing rate, which must be determined by observation after the interval of one or more days. Suppose it is losing 3s a day. Put a weight, which has been carefully ascertained, say 200 grains, upon the plate which covers the jar (E c in the mercurial pendulum, in the gridiron pendulum anywhere near D b), and find the fresh rate of the clock by observation. Let it now gain 10s a day. Then, as 200 grains cause a gain of 13s a day, 46·2 grains will alter it 3s per day, and replacing the 200 grains with a weight of 46·2 grains will bring the clock to time. In an observatory it is always desirable that a clock should have a small losing rate, and be slow rather than fast (the corrections for clock error and clock rate are then additive), so that it would be better to add a smaller weight than 46 grains; and in any case it is more safe to destroy the rate by two operations, especially if the preceding rates were not very carefully determined.

The final adjustment of the compensation can be best accomplished when the clock has gone several months, and when the gain or loss in two of the warmest months in the year is compared with the gain or loss in two of the coldest. Suppose the mean temperature in the summer months of trial to be 30° higher than in the winter months, and that the clock loses 1s more in summer than winter; it is therefore *under-compensated*, and requires more mercury. Add 1 lb. of mercury, and bring it to a close rate exactly as before; and now let it be *over-compensated*, so that an increase of 24° in the temperature causes it to gain 0s·4 per day, which by simple proportion is the same as a gain of 0s·5 by 30° of temperature. Hence it is clear that as 1 lb. of mercury causes an alteration of 1s·5 in the variation due to temperature, if a third of a pound be withdrawn the compensation will be nearly *correct*. A second trial will perfect the compensation, which should never be afterwards disturbed.

Length of Simple and Invariable Pendulum.—The equality of the oscillations of a weight suspended by a line is said to have been used by Ibn Junis, A.D. 1100, and by the Arabian astronomers, for the subdivision of portions of time. (Young, *Nat. Phil.*, vol. i., p. 595.) This property of the pendulum was remarked by Galileo when a student at Pisa, by observing the vibrations of a lamp swinging from the roof of the cathedral, and was by him proposed as a medical instrument for observations on the pulse. (Drinkwater, *Life of Galileo*, p. 5.) The simple pendulum was much used as an astronomical instrument (called *perpendiculum* in the older writers) before it was adapted by Huyghens to the clock. Mouton (*Observationes Diametrorum Solis et Lunæ*, Lugd., 1670) applied the vibrations of the simple pendulum successfully to measure the time in which the sun and moon describe their respective diameters, and in the Appendix, p. 427, proposes his *nova mensurarum geometricarum idea*, i.e. a decimal system of measures based on the value of a minute in Riccioli's length of a degree. This is his *milliare*, the thousandth part of which he calls a *virgula*; and then finds by experiment that the *virgula*, which, according to Riccioli, is 5 ft. 4·363 in. Bolognese measure, is the length of a simple pendulum which makes 3272 oscillations in half an hour.

In 1671 Picart was sent to determine the position of Tycho Brahé's observatory at Uranibourg. He took this opportunity of swinging the pendulum, and found the length of the seconds pendulum 3 ft. 0 in. 8½ l. Paris measure, exactly the same as he had previously found it to be at Paris and subsequently at Cette, on the south coast of France. Romer obtained the same result at London, and these erroneous measures of Picart, the first astronomical observer of his day, were for a long time cited as objections to the theory of gravitation.

In 1672 Richer was sent to Cayenne (about 4° 56′ N. lat.) to make a course of observations, and among the rest to observe the length of the seconds pendulum. His words are: 'L'une des plus considérables observations que j'ay faites, est celle de la longueur du pendule à secondes de temps, laquelle s'est trouvée plus courte en Caïenne qu'à Paris: car la mesme mesure qui avoit esté marquée en ce lieu-là sur une verge de fer, suivant la longueur qui s'estoit trouvée nécessaire pour faire un pendule à secondes de temps, ayant esté apportée en France, et comparée avec celle de Paris, leur différence a esté trouvée d'une ligne et un quart, dont celle de Caïenne est moindre que celle de Paris, laquelle est de 3 pieds 8⅗ lignes. Cette observation a esté réitérée pendant dix mois entiers, où il ne s'est point passé de semaine qu'elle n'ait esté faite plusieurs fois avec beaucoup de soin. Les vibrations du pendule simple dont on se servoit, estoient fort petites et duroient fort sensibles jusques à cinquante-deux minutes de temps, et ont esté comparées à celles d'une horloge tres excellente, dont les vibrations marquoient les secondes de temps.' (*Recueil des Observations faites en plusieurs Voyages par ordre de sa Majesté*,* p. 66. Paris, 1693.) We have cited this passage textually, not only on account of its importance, but because it is generally merely stated that Richer's clock, which was regulated on Paris time, lost more than two minutes at Cayenne. This misrepresents the *evidence* of the experiment, and moreover leaves room to suppose that Richer made a *chance* discovery, whereas the determination of the length of the pendulum was one of the special objects of his mission (see p. 2). Neither Picart nor Richer gives any details of his *modus operandi*.

In 1673 Huyghens published his 'Horologium Oscillatorium,' perhaps the most remarkable mathematico-mechanical work which preceded Newton's 'Principia.' He therein explains the *isochronism* of oscillations in a cycloid, and the mechanical means of making the pendulum swing in a cycloid. He gives theorems for finding the centre of oscillation of several figures, and thence the length of the simple pendulum, corresponding to a compound pendulum of certain forms; and in propositions 19 and 20 (p. 124-5) proves that when the body is the same, the distances of the axes of suspension from the centre of gravity are reciprocally as the distances of the centre of gravity from the respective centres of oscillation, and that the point of suspension and centre of oscillation are convertible. His proposition 25 (p. 151) is on the mode of fixing a universal and perpetual measure, which he proposes should be the third part of a seconds pendulum, and names a *horary foot*.

Newton, in his 'Principia,' lib. i., s. 10, investigates the oscillations of a body in a cycloid, or in any other curve; lib. ii., s. 6, he considers the effects of a resisting medium on a pendulous body; and lib. iii., prop. 19, he determines the figure of the earth, supposing it to be fluid and of uniform density, to be a spheroid of which the equatorial and polar diameters are as 230 : 229. In prop. 20 he computes the lengths of the seconds pendulum and of the degrees of the meridian, which are required on the foregoing suppositions; and he remarks, 'Quod inæqualitas diametrorum terræ facilius et certius per experimenta pendulorum deprehendi possit quam per arcus geographice mensuratos in meridiano.' In the following pages is an analysis of the lengths of the pendulum which had come to his knowledge.

We have not been able to find any account by Graham himself of two very capital improvements which he seems to have introduced into pendulum experiments. The first is a clock, in which 'he carefully contrived that its pendulum might at pleasure be reduced to the same length whenever there should be occasion to remove the clock from one place and set it up in another.' (Bradley's 'Account of the going of a Clock by Graham, in London, and at Black River, Jamaica,' *Phil. Trans.*, vol. xxxviii., p. 302.) Probably this was done by drawing the spring through a slip to a given mark; for in another description of a similar clock it is said the suspending spring was broken. We do not however see need for any adjustment in this respect, if the spring be pinned into the rod and into its upper axis. The pendulum was not compensated, but a thermometer was enclosed in the clock, and as the rate in different temperatures at the same place had been determined, the reduction to a normal temperature was easy. Clocks of this kind were supplied to the French expeditions for measuring arcs of the meridian in Lapland and Peru. For this latter expedition Graham supplied Godin with a *detached* pendulum, which Godin thus describes:—

---

* This volume contains Picart's observations, as well as Richer's.

'Ce pendule est composé en general d'un fil de cuivre, d'une boule de même matiere à un de ses bouts, et d'une piece d'acier taillée en couteau à l'autre bout, qui est celui de suspension: ce couteau porte sur deux montants d'acier en deux points qui designent l'axe du mouvement du pendule.' (*Acad. Roy. des Sciences*, 1735, p. 507.) He says its motion was sensible for eighteen hours. It seems that this pendulum, the vibrations of which were to be counted by a clock, was also intended to measure the actual length of the pendulum. Messrs. Bouguer and La Condamine both had detached pendulums made after Graham's idea. Bouguer (same volume, p. 526) describes this pendulum as an invention of his own; La Condamine (*Journal du Voyage*, p. 143) is more open, and says he took the idea from a copy which Hugo made after Graham's. This is almost exactly Kater's invariable pendulum. Mairan's measurement of the length of the seconds pendulum (*Acad. Roy. des Sciences*, 1735, p. 153) is a good specimen of the old method of measuring the length of the pendulum: and the measures of Godin, Bouguer, and La Condamine, in the same volume, are worthy of notice. For references to various pendulum experiments, see Lalande, *Astronomie*, 3rd edit., s. 2710, *et seq.*

In the first volume of the 'Transactions of the Society of Arts,' p. 238, Mr. Hatton proposed, as a mode of fixing a permanent standard of length, to suspend a weight from a fine hair to a clip in an upright bar, sliding up and down in a vertical frame. The hair passed through a fixed clip. The weight was to be swung, and the vibrations counted, in two positions of the bar, and from the difference in the times of vibration and the space through which the bar was moved, the length of the seconds pendulum was to be computed.

In 1787 Mr. John Whitehurst published 'An attempt towards obtaining invariable Measures of Length,' &c., which is remarkable for its ingenuity. He suspended a leaden ball with a flat steel wire in front of a straight upright frame, the wire being long enough to make forty-two oscillations in a minute. A clock with dead-beat escapement and a clip to hold the wire was slid up and down the frame, and secured and adjustable at two points where the clip made the free oscillations respectively forty-two and eighty-four in a minute The crutch of the clock, being continued upwards in a screw, carried a weight, by moving which the oscillations of the crutch *alone* could be regulated to forty-two and eighty-four oscillations, and *therefore would not interfere with the free oscillation of the ball and wire, but only keep up their motion.* The going weight of the clock was in each case such as sustained an oscillation of 3°. It is clear that if all were properly executed, the clock-frame with its clip must have been shifted between the two positions through a space equal to the difference between the simple pendulums which correspond to forty-two and eighty-four oscillations per minute. A line was drawn in each position along the upper edge of the clock-frame upon a brass rule fixed to the upright support, and this space was afterwards accurately measured, and the length of the simple seconds pendulum thence computed. Whitehurst's length of the seconds pendulum is 39·1196 inches of Troughton's standard, but the corrections for the buoyancy of the air and for temperature are not introduced. It is probable that he introduced greater errors than those he wished to get rid of in Hatton's method, for the real difficulty is not that of counting the vibrations, but of measuring the length between the two clips, in avoiding the errors of temperature and the uncertainty as to the effective point of suspension. The *principle* of Hatton's method, that of measuring the difference between two pendulums, has been adopted, as we shall see, by Bessel.

The foregoing account is merely a sketch of the history of this mechanical problem, which, in the hands of Borda, and more recently of Kater and Bessel, has received a more accurate solution. There are still anomalies and imperfections in some parts of the processes which require clearing up, but the errors have been reduced within comparatively moderate limits. Before describing these experiments we shall give a brief account of the formulæ which they require.

The expression which connects the time of one oscillation of a simple pendulum in an infinitesimal arc, with its length l, at a place where the force of gravity is represented by g, is $t = \pi \frac{l^{\frac{1}{2}}}{g^{\frac{1}{2}}}$, π being 3·141596, or circumference to diameter 1; the measure of gravity, g, being twice the space through which a body would fall freely in 1^s, or, what is the same thing, the space through which a body would move in 1^s, with the velocity which it acquires in falling freely for 1^s.

Hence, if l be the length of the simple seconds pendulum, $g = \pi^2 l$; therefore g is known when l can be measured. The process therefore of finding the effective force of gravity at any place is reduced to finding the length of the simple pendulum which vibrates seconds.

The French astronomers, in their great survey of the arc of the meridian, determined the *absolute* length of the pendulum at different stations between Dunkerque and Formentera, and also in the continuation to Unst in the Shetland Isles, which is included in the English Trigonometrical Survey. It is however an operation of great delicacy, and when only the *variation* of gravity between different places is required, as is the case in researches into the figure of the earth, the observation may be more easily performed by swinging the *same* pendulum in different places, and ascertaining the number of vibrations which it makes in a day. Thus if n and n' be the number of vibrations made in a day by the *same* pendulum l, at two different places at which the forces of gravity are g and g', and the duration of one vibration at each place be t and t', then since the time of one vibration = a day divided by the number of vibrations, we shall have

$$\frac{1}{n} : \frac{1}{n'} :: t : t' :: \pi\left(\frac{l}{g}\right)^{\frac{1}{2}} : \pi\left(\frac{l}{g'}\right)^{\frac{1}{2}} :: \frac{1}{g^{\frac{1}{2}}} : \frac{1}{g'^{\frac{1}{2}}},$$

$$\text{or } g : g' :: n^2 : n'^2.$$

That is, the force of gravity varies as the square of the number of vibrations of a given pendulum in the same time, which is usually taken to be a mean solar day. If therefore the number of vibrations of a pendulum in a day at a given place, London for instance, be known, and it is then transported to different places, and the number of vibrations in a day counted, a simple proportion will compare the forces of gravity at London and every place at which the observation has been made.

If the length l' of the simple pendulum at any station be required from these observations,

$$\text{since } l : l' :: g : g' :: n^2 : n'^2,$$

$l' = \frac{l n'^2}{n^2}$, which gives the length of the pendulum at any place in terms of the length at London, and the number of vibrations per diem at that place and London.

Though it scarcely belongs to our subject, we will give the expression by which the ellipticity of the earth is determined from pendulum observations. The length of the seconds pendulum at any latitude, λ, may be supposed $l = A + B . \sin.^2 \lambda$, where A and B are constant quantities. Now from all the good observations, either of the actual length or the number of vibrations per day of the same pendulum, determine the values of A and B; then by Clairaut's theorem,

$$\text{the ellipticity of the earth} =^{*} {\cdot}008668 - \frac{B}{A};$$

whence the ellipticity is found. By ellipticity is meant the excess of the equatorial over the polar radius of the earth, divided by the polar radius.

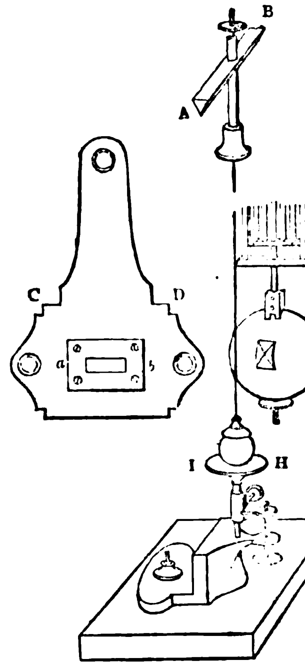
The apparatus of Borda will be generally intelligible from the following description and perspective plate.

The plumb-line is suspended from a knife-edge piece A B, and is attached below to a cup E, which is ground to fit very exactly the platina ball below. A little grease is rubbed on the inside of the cup, making the contact perfect enough to exclude the air and to suspend the ball. The knife-edge rests on agate planes, a, b, which are carefully levelled, and the frame C D, which carries the planes, is fixed immoveably in a horizontal position. The plumb-line is in front of the comparing clock, which has a small cross drawn on the bob. When both are at rest, a telescope having a vertical line in the focus is placed a few feet distant, so that the cross, the plumb-line, and the fixed wire of the telescope are all in the same right line, and all seen to

---

* This is Mr. Airy's value for $\frac{5m}{2}$ where m is the ratio of the centrifugal force at the equator to the force of gravity there. (*Encyclopædia Metropolitana*, 'Figure of the Earth,' sect. 2.) Biot, *Astronomie*, vol. 3, ad finem, [illegible] gives 0·00863; the centrifugal force m being supposed $\frac{1}{289}$ of the force of gravity at the equator.

*anctly.** Such a length is given to the plumb-line, as that its oscillations shall be a little slower than those of the clock.



Borda's Pendulum apparatus.

The clock is now set a-going, and when it is quite steady, the platina ball is drawn a little on one side, and made to swing through a very small arc, one or two degrees at the most. The observer then places himself at the telescope, and notes the exact beat of the clock when the plumb-line meets the cross and coincides with the fixed wire at the same time: this is called a *coincidence*. As this observation seems much less definite than in Kater's method, it is better to note those beats before and after the coincidence, when the eye cannot distinguish whether it is a coincidence or not, and to take the mean of the two for the true time of coincidence. Immediately after, the extent of the arc through which the plumb-line swings is to be read off on a scale placed just behind it; the thermometers which are near the pendulum must also be read off, and the height of the barometer. The observer now waits until this appearance presents itself a second time (which may be in about ten minutes, though the interval is quite *ad libitum*), and having thus established the time which elapses between the observations, he may leave the apparatus for three, four, or five hours, when on his return the same observations must be repeated of coincidence, arc, temperature, and barometer, and the series is finished. We should recommend closing as well as commencing a series with two coincidences *ad majorem cautelam*, but except as a check, no observations are required except the first and the last. The plumb-line is again set in motion exactly as before, and the second, third, and following series observed. The rate of the clock is established by astronomical observation.

After a satisfactory number of series has been taken, the next object is to measure the length of the pendulum. The plane I H is raised by a fine screw until it just touches the bottom of the platina ball. This is an operation of great delicacy, and must be effected by two or three trials, as the *exact* temperature of the wire at the *exact* moment of contact is required; and the presence of the observer, even for a short time, is sufficient to affect a slight wire very sensibly. Suppose this done, the apparatus is removed or moved on one side, and a bar, which has a knife-edge above and a sliding tongue below, is suspended in its place. The tongue is slid down until it touches the plane I H, and the distance between the knife-edge and the bottom of the tongue measures the distance between the top and bottom of the pendulum. This distance may be measured in several ways; the French astronomers use a contrivance which need not be described here.

One of the great practical difficulties in this species of pendulum experiments seems to be the extreme and sudden sensibility of the plumb-line to temperature. The whole apparatus is enclosed in a glass cage to exclude currents of air, and the observer is particularly careful, after bringing the lower plane into contact with the bottom of the ball, to absent himself until the temperature is steady, and then to make the contact complete. It is another objection that the different manipulations required are of great delicacy, and therefore not suited to every observer and every place; but when the utmost care and skill are employed, the results appear satisfactory.

The knife-edge, A B, by which the line and ball are suspended, is an ingenious contrivance, exactly similar to Whitehurst's synchronous crutch above described. By the upper screw and weight, the oscillations of the knife-edge *alone* can be made synchronous with the oscillations of the whole pendulum, so that the oscillations are just the same as if the knife-edge were immaterial, and the point of suspension exactly in the line of its edge. The platina ball can be suspended from any side, and if two positions diametrically opposite be taken, the effect of any irregularity of shape or density disappears from the mean of the two results. There are several corrections to be applied to the quantities immediately given by observation, before the length of the simple pendulum can be concluded. The oscillations are made in an arc of sensible extent. Now the time of oscillation in an arc of A° on each side the lowest point, is greater than the time in an infinitely small arc (which is the arc required), in the proportion of $1+\frac{\sin.^2 A^\circ}{16}$ to 1. An expression which depends upon the first and last arcs of each series, gives the correction which is to be added to the number of oscillations observed. This is taken from a table. Between each coincidence, the plumb-line has made two oscillations less than the clock, therefore subtracting twice the number of coincidences from the number of seconds elapsed between the first and last coincidences, you will have the number of oscillations of the pendulum during a certain time shown by the clock. Each of these numbers requires a correction: to the number of oscillations of the pendulum, must be added the correction for arc just mentioned; and to the time as shown by the clock, the proportional part of its rate during the experiment. A simple proportion will now give the number of infinitely small vibrations in 24 hours.

Further corrections are to be applied. The length of the wire and ball during the observations must be reduced to the length they would have had at the temperature when the contact with the plane and the measurement was made, and this again must be converted into the equivalent length when the thermometer is at the freezing-point, which is the French standard temperature. The theoretical pendulum is supposed to swing *in vacuo*, and as the density of the air affects the time of oscillation two ways, both by diminishing the moving force of the pendulum and by adding* to its inertia by the air carried along with it, a correction is required on this account, which depends upon the barometer and thermometer, on the specific gravity of the materials of the pendulum, and also on its form.

From the dimensions and specific gravities of the parts of the apparatus, the distance between the centre of oscillation and the bottom of the ball can be computed. Hence the length of the simple pendulum, which oscillates in an infinitely small arc a certain number of times in a day and *in vacuo*, can be assigned, from which the length of the seconds pendulum is deduced by simple proportion.

If the place of observation be above the level of the sea, it is usual to reduce the length to what it would have been at the sea-level. This is a very uncertain quantity, as it depends upon the configuration and density of the strata in and near the spot. In the earlier experiments gravity was supposed to vary inversely as the square of the distance from the centre of the earth, and thus the attraction of the matter between the observer and the sea-level was wholly neglected. Dr. Young showed that in a table-land of average density the correction thus obtained was too large, and should be multiplied by 0·66.

---

* This is not always practicable, and it would, generally speaking, be better to place a lens between the cross on the clock-bob and the plumb-line, and to throw an image of the cross upon the plumb-line. It is desirable on many accounts that the two pendulums should not be very near each other

* This part of the correction due to the air was omitted in the French experiments and in Captain Kater's: see Mr. Baily's memoir referred to above, and Air.

For a full description of Borda's method, with instances, &c., see *Base du Système Métrique Décimal*, vol. iii., p. 337 (Borda's original memoir); and again, vol. iv., p. 441 ('Observations from Formentera to Unst').

Many modifications and improvements have been introduced into Captain Kater's method of determining the length of the pendulum, and we must refer to his paper (*Phil. Trans.*, 1818, p. 33) for a minute description and for a plate of his apparatus.

The principle of his method is founded on the beautiful dynamical theorem due to Huyghens, which we have already mentioned, namely, that the axis of suspension and centre of oscillation are reciprocal in the same body. Now conceive two wedge-formed pieces of steel (knife-edges), with the sharp edges towards each other and parallel, to be fixed at right angles to a bar of any form whatsoever, and in a line passing through its centre of gravity; then if the time of oscillation on either edge be the same, the distance between the knife-edges is the length of the simple pendulum which swings in the same time. Captain Kater, in his experiments, used a pendulum of an inconvenient form, the same nearly as in his invariable pendulum (see cut of Kater's invariable pendulum), with a second knife-edge below the centre of the bob, and there are several doubtful points in the reductions which he employed and the subsequent measurement between the edges; still his memoir must always be carefully perused by any future experimenter who wishes to make himself thoroughly acquainted with the subject. The method of observing the coincidences is remarkably ingenious and accurate.

Baily's Convertible Pendulum.

We conceive that the best form of pendulum for the object of measuring the actual length according to Kater's method is that adopted by Mr. Baily. A C is a rectangular bar, with one knife-edge at the end A, and the other at B, about ⅔ of the length from the same point. A should be as near the end as sound workmanship will allow. The necessary verifications, namely, the parallelism of the knife-edges, their perpendicularity to the bar, and that the line which joins the knife-edges passes also through the centre of gravity, are all very simple, and there is little difficulty in adjusting the oscillations on each knife-edge to synchronism.[*] This bar pendulum is suspended on agate planes in front of the clock, great care being taken that the support is perfectly firm and the agate planes horizontal. A white disc of a spindle shape and exactly the width of the bar is pasted on the clock bob, and the viewing telescope fixed in a line with the disc and bar, so that, both being at rest, the white disc is just covered by the bar. Captain Kater used a diaphragm in his telescope, the sides of which were parallel to the bar and touched its edges; but it has been found more convenient to place a pair of parallel plates between the bar and the disc, the sides of which are so adjusted as just to allow the disc on the clock bob to be seen between them. There is a divided scale to mark the arc of vibration, two or three thermometers hung at different heights about the pendulum bar to register the temperature, and a barometer for the atmospheric pressure, all which are to be read at the beginning and end of each series. The observation itself is of the simplest kind. Set the clock going, and when its arc is steady, give the pendulum a small motion, 1° or 1½° at the utmost. The white disc, which is at first wholly visible, is gradually invaded by the bar, till at last it is entirely covered, first one side and then the other disappearing.[†] These times of *disappearance* are to be noted. Almost immediately after, the white edges reappear, first on one side and then on the other, and these *reappearances* are noted. The mean of the four gives the tru time of coincidence. It has been found convenient practice not to make the adjustments with the hig degree of precision, for you are then in doubt on w side the first disappearance and reappearance will ta place; whereas if there is a very little displacement, atte tion need only be fixed on every alternate beat, which less strain on the eye and on the mind. This displaceme however must be trifling, otherwise, when the arc becomes small, the disappearances and reappearan will not take place. The reductions for the rate of clock, for the arc of vibration, the temperature, the bu ancy of the air and its inertia, and the height of the p of observation above the sea-level, are all to be made as Borda's pendulum. For the details we refer to the standa memoirs which have been published on the subject. B there are two or three points which deserve more atten than they have generally met with. The clock is only be considered as a counter of the vibrations, and to av any error arising from its irregular rate, the observat should be continued without intermission between t epochs, at each of which the error of the clock is ascertained by astronomical observation. If this be done, t only reliance upon the clock is for the short time wh elapses between the last coincidence of one series and first of the next. It is true that this mode of observi requires artificial illumination, for it must be continued d and night. This is no disadvantage, but the contrary, as the other great practical difficulty is that of ascertaining the exact temperature and keeping it steady, the best pl for observation is a deep roomy vault or cellar.

The correction for the buoyancy of the air depends on th *specific gravity* of the pendulum; that arising from t dragged air, which we have called inertia, on its *form*. I is very desirable that the experiments should be made *vacuo*, and where that is difficult or impossible, as in a travelling apparatus, the law and quantity of the correction f each pendulum should have been previously experiment determined *in vacuo*. The variation for temperature shou be got from a comparison of summer and winter experiments at the same place. In addition to the height the place of observation above the sea-level, a rough survey should be taken of the form of the surrounding country, and of the kind of strata, with the specific gravity each. This is particularly necessary where the heights are considerable. (See Young's remarks, 'Phil. Trans.,' 1 p. 93.)

Still, when every known precaution has been taken, there are anomalies in the results of this experiment which a not yet clearly understood. It is very difficult to make t edge of the knife perfectly straight, and to keep it so wi it is fastened to the bar. There is considerable uncerta in measures of distance between the reciprocal kn edges; and lastly there is no authorised standard of leng at present existing in England in terms of which t distance can be expressed. The length of the sim pendulum which vibrates seconds in the latitude of L don is not at present known with the degree of certain which the importance of the problem demands, and wh is attainable.

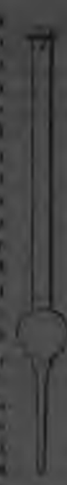
Captain Kater proposed the following form of pen lum for determining the number of oscillations which same pendulum describes in different places, which is ne the same as Graham's above described. Mr. Baily pr the bar with two knife-edges, the same as that used determining the absolute length, and he directs obser tions to be made at each place with both knife-edges. T is certainly a great advantage in having a check upon t knife-edges, as a discrepancy between the two results posing the pendulum to have been previously

---

[*] This may be done two ways. Place the knife-edges A and B at the distance which will give the proper interval for coincidences, 39·4 inches for instance, A being at one end, and make the bar rather more than one-third longer; then the oscillations on B will be slower than those on A. By filing from the end C, these may be made to agree after two or three trials, or if the pendulum should be too short, a weight may be added at this end, such as is pointed out by the black dot near C.

[†] Mr. Baily uses two slips of gold-leaf pasted on a tail to his clock pendulum for a disc, which answers very well. In the experiments at Dolcoath mine, Messrs. Airy and Whewell had a disc of enamel at the end of a small rod, which was screwed into the bob and projected from it. The disc could be inclined so as to appear of the proper breadth and to receive an oblique illumination. This part of the experiment is almost irreproachable, but perhaps in uture it would be safer to place the clock and pendulum at greater distances rom each other, and to get sharp edges by interposing a lens.

[*] Captain Kater's measure was doubtful in several respects, and though been partially corrected, it is still uncertain. He expressed the length pendulum in terms of Sir George Schuckburgh's scale (which has suffered injury since that time), and this he found to be identical with liamentary measure declared to be standard by the 5 George IV. act of parliament standard was destroyed when the houses of parliame burned. Fortunately a very beautiful scale of 5 feet had been for the Astronomical Society, and three feet in this scale had been many hundred times with the parliamentary standard. As almost all scales and comparisons which have been made in England have been with this last-mentioned scale, it must be considered to be the standard, and the best evidence of the parliamentary standard wh The definition for restoring the yard, if lost, according to the act of that is, by the length of the seconds pendulum, as it depends upon an determination, would give a new standard, differing sensibly from the one which it was meant to preserve. (Baily's 'Report on a Standard *Astron. Soc. Mem.* vol. ix., p. 35.)



Kater's Invariable Pendulum.

lated) will show that one of the knife-edges has been injured. To ascertain which of the two it is, requires a second pendulum. Upon the whole, though we prefer Mr. Baily's pendulum to Captain Kater's, yet we think a form suggested by Mr. Airy is, for ordinary purposes, still better—that is, to have the knife-edge placed in that part of the bar where the oscillations take place in the shortest time. In this case it seems probable that any ordinary injury of the knife-edge will not alter the time of vibration. The observer must be very careful in these stiff bars to see that the pendulum is truly vertical, a precaution which in Kater's flexible bar is less necessary. If an observer chooses to have a second knife-edge opposite the former in the pendulum of minimum vibration, there is no objection except the increased resistance of the air, the increased correction for inertia, and the chance of confounding the two positions. The mere observation of the coincidences, which in its present form was first introduced by Kater, is so simple that it will be successfully performed by any person the first time of attempting it; and an error of a second or two in noting the moment is a matter of little importance. There is far greater latitude for error in noting the temperature and ascertaining the clock-rate, but there is another anomaly attending the knife-edge pendulums, only partially understood at present, which is much more vexatious than temperature or clock-rate. As the pendulum swings about those points of the knife-edge which are in contact with the agate planes, it is clear that, supposing any imperfection in both, those points may be altered, when the axis of suspension, and consequently the time of oscillation, will be altered too. Hence it is advisable to place the knife-edge as exactly as possible always in the same position on the agate plane, both as to front and back, and also as to right and left. It will generally be found that turning the pendulum half round on the same knife-edge will alter its time of vibration sensibly, so that the face in front must always be registered. But even when these precautions are taken, anomalies are still found, which we can only attribute to the following cause:—In most of the pendulums hitherto made the steel knife-edge has been fixed upon a bar of different metal (brass and copper) with stout brass knees, and the two screws which fix the steel knife-edge to the brass knees are at some distance from each other. Now if, from the difference of expansion between the brass knees and the knife-edge, the latter should be curved, not upwards or downwards, but in a horizontal plane, the consequent alteration of time in the oscillation may be very considerable. The steel edge therefore should either be controlled by being ground on a narrow slip let into a brass wedge, or the attaching knees should also be of steel. The uncertainty which appears due to some such cause as that above described may amount to one, two, or even more seconds a day in the invariable pendulum, either of Kater's or Baily's construction. It is evident that in measuring the actual length of the pendulum this error may be further increased, for the problem assumes the perfect parallelism and truth of a pair of knife-edges. For an account of knife-edge bar pendulums, see 'Kater's *Convertible* Pendulum, with Young's Appendix,' *Phil. Trans.*, 1818, p. 33; 'Kater's *Invariable* Pendulum,' *Phil. Trans.*, 1819, p. 337; Sabine's 'Experiments to determine the Figure of the Earth,' London, 1825; Sabine's 'Comparison of the Length of Pendulum at London and Greenwich,' *Phil. Trans.*, 1829, p. 83; Sabine, 'On the Reduction to a Vacuum,' *Phil. Trans.*, 1829, p. 207; Baily, 'On the Reduction to a Vacuum,' *Phil. Trans.*, 1832, p. 399; Foster's 'Pendulum Experiments, edited by Mr. Baily,' *Mem. Ast. Soc.*, vol. vii. (at page 96, is given a table of the results of the most accurate modern pendulum experiments).

The last important measurement of the length of the pendulum, which is undoubtedly the most satisfactory, is due to Bessel, and is described by him in his 'Untersuchungen über die Länge des einfachen Secundenpendels,' Berlin, 1828, which forms part of the 'Transactions of the Academy of Berlin.' The principle of his measure is the same as Whitehurst's. Bessel procured from Paris a verified copy of the toise of Peru; this he placed upright, and suspended his ball and wire first from the top and then from the bottom of the toise, the ball being in both cases at the same point below; the time of oscillation in each position was compared with a clock in front. From the differences of the times of oscillation of these two pendulums, and the difference in their length, which is a toise, the length of the seconds pendulum was computed in parts of the toise. Bessel suspended his pendulum by passing a flat and very slender spring over a small cylinder, the spring being continued downwards to the ball in a fine wire. We must refer to the original memoir for a description of the different elaborate contrivances which were introduced by Bessel and Repsold for securing accuracy in every part of the process. All conceivable causes of error are considered, and the effects have been computed and allowed for. The final result is that the length of the seconds pendulum at the sea-level in the latitude of Königsberg, 54° 43′ N., is 440·8179 lines of the toise of Peru; this we consider to be a measurement of the actual length of the pendulum which is deserving of full confidence, and perhaps the only one.

We have already pointed out the manner in which experiments with the pendulum are used to determine the figure of the earth, and stated that for this purpose the simple bar with a knife-edge at the point of minimum oscillation seems the most fit. If the present imperfections can be overcome, which we see no reason to despair of, there is another research, that of the mean density of the earth, for which such an instrument is peculiarly adapted. The density which has been hitherto [illegible], depends on the attraction of Schehallien upon a plumb-line, observed by Maskelyne, and upon the attraction of leaden balls measured by a torsion balance, according to Cavendish, and more recently by Reich. Now in the Schehallien experiment the whole deflection caused by the mountain was only 11″·6, which, under the circumstances, might very easily be 2″ or even 3″ wrong either way. The Cavendish experiment is repeating in this country, but up to the present time the results give very moderate hopes of ultimate success.

If an invariable pendulum can be made which is only affected by known causes of which the effects can be calculated, the simplicity and perfection of the observation by coincidences, and the unlimited time for which it can be carried on, will supply a much broader and more secure base for the solution of this important problem, and one more readily and universally applicable. Two attempts were made by Messrs. Airy and Whewell, first by themselves, in 1826, and afterwards, in 1828, with the assistance of three Cambridge friends, to deduce the mean density of the earth from observing the oscillations of detached pendulums at the top and bottom of Dolcoath Mine, one of the deepest in Cornwall. As the first operation was less carefully planned, we shall confine our account to the second, which was altogether the best arranged pendulum experiment which has come to our knowledge, and only failed from a cause then first discovered, viz. that invariable pendulums of Kater's construction are very uncertain and inaccurate instruments. We will call the two pendulums 1 and 2. These were placed on their stands opposite each other, and put into motion at the same arc (a board being interposed to prevent their reciprocal action through pulses of the air), and the times of coincidences observed. A few series were thus made, in which the errors of observation scarcely amounted to a hundredth of a second per day.* Pendulum 1 was then sent to the bottom of the mine, and set up with its clock and proper accompaniments. Pendulum 2 was established with its clock in a hut at the surface. We will call the observers A, B, C, D, E. A set off at six in the morning, commenced a series with pendulum 2, and compared eight pocket chronometers with the clock by coincident beats through a sidereal half-seconds chronometer.† He then descended the mine and commenced a series, compared his chronometers below exactly as he had done above, and then sent them back to the upper station. By this time E had arrived at the upper station to finish the series which A had begun, and to compare the chronometers on their return. In this way the clocks were compared, without a possible error of $\frac{1}{50}$th of a second. After finishing his first series and commencing a second, A returned to day (in the miner's language, to *grass**). This series was completed by B, who set off at 2 P.M., made a third shorter series, and commenced a fourth. The night-work was taken by C or D, one of whom descended at 10 P.M., finished B's series, and commenced a fresh one; on his return to day he finished the upper series which E commenced before going to bed, and started another, which was finished by A before his next descent. In this way observations were continued from Monday morning, July 11, to Saturday afternoon (127 hours). On comparing the results of each day, it was found that the three first days agreed extremely well, showing an acceleration of about 2^s per day in the lower pendulum; but the two next days, this acceleration was about double. The only mode of accounting for this unexpected and very unwelcome result was, that the knife-edges and agate planes were imperfect, and that the time of oscillation depended on the position of the pendulum on its plane. This had never been suspected before; for confidence in the accuracy of the pendulum was at that time almost an article of faith among experimentalists. To ascertain this, a second series of comparisons was made between pendulum 1 and 2, taking care to place the knife-edges exactly in the same position on their planes, and that the faces were turned the same way. These comparisons were necessarily hurried, as a slip had taken place in the mine near the engine-shaft, which deranged the action of the pumps, and forced the experimenters to repeat their operations below without delay. Pendulum 1 was again sent below, and the experiment repeated exactly as described above, for three days (79 hours), until the underground observers were driven out by the water. Notwithstanding all the precautions which had been taken,† the observations of the last day gave a different result from the two first. 'The conclusion therefore on which the experimenters were unavoidably forced was, that even with the care and attention they had used, the pendulum could not be trusted.' The pendulums were a third time compared with each other above ground, and the intervals of coincidence were found to vary, without any assignable cause, from $20^m\ 24^s$ to $20^m\ 17^s$, and back again from $20^m\ 20^s$ to $20^m\ 29^s$; and finally, *during one series of oscillation, without being touched, or any one entering the room*, the time of coincidence changed from $20^m\ 25^s$ to $20^m\ 13^s$, and at last to $20^m\ 3^s$. It was therefore clear that while the mode of observing was perhaps sufficient to detect a difference of a hundredth of a second a day (except from the effects of temperature, which might amount to a tenth of a second), the pendulums themselves, though used with the utmost skill and precaution, and *under the same circumstances*, were liable to errors of two seconds or more per day.

---

* In a series of six hours, the first and last coincidences could be so observed as not to admit an error of more than 2ˢ for the whole interval, and the coincidences followed each other in about 10 minutes. A bright strip was [illegible] on each edge of the tail of the [illegible] and [illegible] pendulums, and this was [illegible] by a lens placed obliquely. The corrections for arc, thermometer, barometer were the same for each. The time was taken from an excellent chronometer.

† The comparison of a single chronometer was generally sure to within $\frac{1}{100}$th of a second, generally within $\frac{1}{50}$th. The ½ seconds sidereal chronometer was compared first and last with the pendulum clock, giving nearly coincidences, and in the interval [illegible] coincidences of each pocket chronometer (which [illegible]) were observed with the sidereal chronometer.

PENE'ROPLIS, De Montfort's name for a genus of microscopic *Foraminifera*.

PENEUS. [THESSALY.]

PENGUINS, *Manchots* of the French, a group of natatorial birds, in which the wing, powerless as an organ of flight, is reduced to a mere rudiment as far as feathers are concerned; but it well assists the bird as a species of fin in its rapid divings and evolutions under water, and even as a kind of anterior extremity when progressing on the land. They seem to be among the *Natatores* what the *Struthionidæ* are among the strictly terrestrial birds.

Prodigiously active in the water, but helpless on the land, their lot has been wisely cast on those desolate southern islands and shores where man rarely intrudes, and in many instances where a churlish climate or a barren soil offers no temptations to him to invade their territory. They seem to occupy in the southern hemisphere the place filled by the Auks in the northern portion of the globe.

Before we enter into the details of the organization of these birds, or an inquiry as to the views of Ornithologists relative to their proper place in the system, it will be necessary to notice the various accounts of the habits of this very curious and interesting group. Le Vaillant, in pursuing his investigations on Dassen Island, where was the tomb of the Danish sea-captain, as noticed in the article PELECANIDÆ, found that the smaller crevices of the rocks served as places of retreat for *Penguins* (*Spheniscus*, probably), which swarmed there above every other kind. 'This bird,' says Le Vaillant, 'which is about two feet in length, does not carry its body in the same manner as others: it stands perpendicularly on its two feet, which gives it an air of gravity, so much the more ridiculous, as its wings, which have no feathers, hang carelessly down on each side: it never uses them but in swimming. As we advanced towards the middle of the island, we met innumerable troops of them. Standing firm and erect on their legs, these animals never deranged themselves in the least to let us pass; they more particularly surrounded the mausoleum, and seemed as if determined to prevent us from approaching it. All the environs were entirely beset with them. Nature had done more for the plain tomb of the poor Danish captain than what proceeds from the imagination of poets or the chisels of our artists. The hideous [illegible], however well sculptured in our churches, has not half so dead and melancholy an air as the penguin. The mournful cries of this animal, mixed with those of the sea-[illegible], impressed on my mind a kind of gloom which much disposed me to tender sensations of sadness. My eyes were for some time fixed on the last abode of the unfortunate traveller, and I gave his manes the tribute of a sigh.'

Sir John Narborough says of the *Patagonian Penguins*, that their erect attitude and bluish-black backks contrasted with their white bellies might cause them to be taken at a distance for young children with white bibs. The towns, *camps*, and *rookeries*, as they have been called, of these birds, have proved an ample theme for most of the southern voyagers. Those at the Falkland Islands have attracted particular attention. Some of these assemblies are described as giving a dreary, not to say awful impression of the desolation of the place and the utter absence of the human race. In some of the towns, it is stated, there was a general stillness, and when the intruders walked among the feathered population, to provide themselves with eggs, they were regarded with side-long glances, but they seemed to carry no terror with them. In many places the shores are covered with these birds, and three hundred have been taken within an hour; for they generally make no effort to escape, but stand quietly by whilst their companions are knocked down with sticks till it comes to their turn. Cook, speaking of the islands in the high latitudes of the South, describes the cold as intense; the islands were covered with hoar-frost and snow, neither trees nor shrubs appeared, and he saw no living creature except the shags and penguins, the last being so numerous that they seemed to encrust the rock.

Some describe the *rookeries* as designed with the utmost order and regularity, though they are the resort of several different species; a regular camp, often covering three or four acres, is laid out and levelled, and the ground disposed in squares for the nests, as accurately as if a surveyor had been employed: their marchings and countermarchings are said to remind the observer of the manœuvres of soldiers on parade. In the midst of this apparent order there appears to be, according to the same account, not very good government, for the stronger species steal the eggs of the weaker, if they are left unguarded, and the *King Penguin* (*Aptenodytes Patachonica*) is the greatest thief of all. Three species are stated to be found in the Falkland Islands; two of these, the *King* and the *Macaroni* (*Aptenodytes chrysocome*) deposit their eggs in the *rookeries*. The *Jackass* (*Aptenodytes demersa*), which is the third, obtaining its English name from the horrid brayings which it sets up at night, makes its nest in burrows on downs or sandy plains, and does not seem to take invasion so quietly as the other species. This, we conceive, must have been the penguin noticed by Forster, who describes the ground as everywhere so much bored that a person in walking often sinks up to the knees; and if the penguin chance to be in her hole, she revenges herself on the passenger by fastening on his legs, which she bites very hard.

But the dimensions of the *rookeries* above noticed sink into insignificance when compared with a settlement of

---

* A miner divides the visible world into two parts, *underground* and *at grass*.

† A considerable difference was found in the temperature of the upper and lower part of the hut during the first upper ground experiment, from the heat of the lamp for illuminating the disc, which was kept continually burning. Before the second experiment, a side lobby was boarded off, in which the observer placed the illuminating lamp a minute or two before the coincidence took place. The lamp-light was thrown by a reflector on the disc through a hole in the boarding; and when the coincidence had been observed, the lamp was withdrawn and the hole stopped with flannel. The clock-face was illuminated for a short time before coincidence by a lamp with a powerful reflector through a hole in the front partition, which was also withdrawn and the hole stopped when the observer had caught the number of the beat. With these precautions, the temperature was perfectly steady, and sensibly the same at all altitudes and throughout the 24 hours.

King Penguins (Ap. Patachonica) recorded by Mr. G. Bennett, who saw at the north end of Macquarie Island, in the South Pacific Ocean, a colony of these birds which covered an extent of thirty or forty acres. He describes the number of Penguins collected together in this spot as immense; but observes that it would be almost impossible to guess at it with any near approach to truth, as, during the whole of the day and night, 30,000 or 40,000 are continually landing, and an equal number going to sea. 'They are arranged, when on shore, in as compact a manner and in as regular ranks as a regiment of soldiers; and are classed with the greatest order, the young birds being in one situation, the moulting birds in another, the sitting hens in a third, the clean birds in a fourth, &c.; and so strictly do birds in similar condition congregate, that should a bird that is moulting intrude itself among those which are clean, it is immediately ejected from them. The females hatch the eggs by keeping them close between their thighs; and if approached during the time of incubation, move away, carrying their eggs with them. At this time the male bird goes to sea and collects food for the female, which becomes very fat. After the young is hatched, both parents go to sea, and bring home food for it; it soon becomes so fat as scarcely to be able to walk, the old birds getting very thin. They sit quite upright in their roosting-places, and walk in the erect position until they arrive at the beach, when they throw themselves on their breasts, in order to encounter the very heavy sea met with at their landing-place.'

Mr. Bennett mentioned several instances of the appearance of Penguins at a considerable distance from any known land. They generally however indicate its neighbourhood. (*Zool. Proc.*, 1840.)

Captain Fitz-Roy gives the following interesting account of the mode in which penguins feed their young. The species on which he made his observations at Noir Island was probably the *Jackass Penguin*.

'Multitudes of Penguins were swarming together in some parts of the island, among the bushes and "tussac" (thick bushy grass) near the shore, having gone there for the purposes of moulting and rearing their young. They were very valiant in self-defence, and ran open-mouthed, by dozens, at any one who invaded their territory, little knowing how soon a stick would scatter them on the ground. The young were good eating, but the others proved to be black and tough when cooked. The manner in which they feed their young is curious and rather amusing. The old bird gets on a little eminence, and makes a great noise (between quacking and braying), holding its head up in the air, as if it were haranguing the penguinnery, while the young one stands close to it, but a little lower. The old bird, having continued its chatter for about a minute, puts its head down and opens its mouth widely, into which the young one thrusts its head, and then appears to suck from the throat of its mother for a minute or two, after which the clatter is repeated, and the young one is again fed; this continues for about ten minutes. I observed some which were moulting make the same noise, and then apparently swallow what they thus supplied themselves with; so in this way, I suppose, they are furnished with subsistence during the time they cannot seek it in the water.' (*Voyages of the Adventure and Beagle*, King.)

Mr. Darwin pleasantly relates his encounter with one of these birds on the Falkland Islands. 'One day,' says our voyager, 'having placed myself between a penguin (*Aptenodytes demersa*) and the water, I was much amused by watching its habits. It was a brave bird; and, till reaching the sea, it regularly fought and drove me backwards. Nothing less than heavy blows would have stopped him; every inch gained he firmly kept, standing close before me, erect and determined. When thus opposed, he continually rolled his head from side to side, in a very odd manner, as if the power of vision only lay in the anterior and basal part of each eye. This bird is commonly called the jackass penguin, from its habit, while on shore, of throwing its head backwards, and making a loud strange noise, very like the braying of that animal; but while at sea and undisturbed, its note is very deep and solemn, and is often heard in the night-time. In diving, its little plumeless wings are used as fins; but on the land, as front legs. When crawling (it may be said on four legs) through the tussocks, or on the side of a grassy cliff, it moved so very quickly that it might easily have been mistaken for a quadruped. When at sea, and fishing, it comes to the surface for the purpose of breathing, with such a spring, and dives again so instantaneously, that I defy any one at first sight to be sure that it is not a fish leaping for sport.' (*Voyages of the Adventure and Beagle*; Darwin, *Researches in Geology and Natural History*.)

Bougainville endeavoured to bring home a penguin alive; it became so far tame that it followed the person who fed it; it ate bread, flesh, or fish; but its fare appears to have been insufficient or inappropriate, for it fell away and died. We have sometimes thought that the *Four-footed Duck* of Gesner might have owed its origin to an ill-preserved penguin, and the notion of its being four-footed might have been fortified by some voyager who had seen the bird making progress as Mr. Darwin has above described. There is a larger figure than Gesner's, headed 'Cane à quatre pieds,' in the *Portraits d'Oyseaux*. Both are evidently much indebted to the imagination of the artist.

Organization.

An elaborate dissection of an adult male Patagonian Penguin, *Aptenodytes Patachonica*, Forst., the total length of which, measured over the back, was three feet two inches six lines, is given by Mr. Reid. The whole will well repay the reader for the time occupied in perusing it; but our limits will allow us to give little more than a portion of his description of the osseous parts. The specimen was captured at East Falkland Isle, lat. 51° 32′ south.

Mr. Reid describes the bones as very hard, compact, and heavy, having no apertures for the admission of air; but they contain, especially the bones of the extremities, a thin oily marrow. The *foramina* for the transmission of the blood-vessels of the bones are small. The *periosteum* is thick and fibrous. The *cranium* is short and broad, and is united into a single bone, with very little appearance of suture or harmony: superiorly, it is flattened; posteriorly, towards the *occiput*, it is rounded; it declines obliquely forwards, and when it attains the front of the orbits it is suddenly truncated to meet the superior mandible. The orbits are large, and separated only by membrane. Above each orbit there is a *fossa*, which is deeper and broader behind than in front, and which ends suddenly at its union with the orbitar process of the temporal bone. External and inferior to the termination of the transverse ridge of the occipital bone there is a process. The temporal bone has two processes; the tympanic, situated immediately anterior to the last-named process; and the orbitar, situated immediately behind the posterior part of the orbit. The basilar process of the occipital bone is short, ending posteriorly in a single round prominent condyle, which articulates with the *atlas*. The body of the sphenoid is lengthened, and its pterygoid processes form separate bones. The tympanic bones have the internal process much produced. The *jugum* is very long and thin, attached, as usual, to the tympanic and superior maxillary bones. The palatine bones are long and thin, meeting posteriorly the pterygoid, and anteriorly the superior maxillary bones.

The upper jaw is immoveable; the superior mandible long, slender, and a little arched at the point. The apertures for the nostrils are long and narrow. The bones of the superior mandible are of the usual form. The superciliary bones are wanting. The lachrymal bones are small, and fixed to the *os frontis*. The turbinated *laminæ* are small, soft, and cartilaginous.

The lower jaw is long and slender, and composed of three pieces, viz. the body of the bone and its two articulating portions. The coronoid processes are very small. The condyloid process is not elevated above the body of the bone. There is a process produced posteriorly for the attachment of the pterygoid muscles.

The *os hyoides* has the lateral *cornua* much lengthened, passing upwards posteriorly to the occipital bone, then curved forwards for a short distance upon the temporal bone.

The vertebral column consists of—

Cervical *vertebræ*	13
Dorsal	9
Sacral	12
Caudal	8
In all	43

The ribs are nine in number, and of the usual form; the two upper ones are not connected with the *sternum*. The oblique processes are situated halfway between their vertebral and sternal extremities. They commence cartilaginous at the inferior margin of each rib, and are about five lines broad at their origin; towards their termination they spread laterally to the width of one inch. As they approach the lower rib they get gradually thinner. In the first and last rib they are totally wanting. The last rib, at its centre, has a surface concave externally, produced by the action of the thigh. The sterno-costal bones are seven in number; the last one curved suddenly at its costal end. The body of the *sternum* is long. The keel is much developed at its top, and forms a very acute angle posteriorly, terminated by a small line. The space for the attachment of the middle pectoral muscle is considerably larger than that for the attachment of the great pectoral. On each side of the keel there is a large space, terminating inferiorly in one, owing to the shortness of the middle layer compared with the lateral ones. The keel terminates abruptly inferiorly. The ensiform process has a ridge in the middle, along which and the inferior edge of the keel a membrane was attached (which separated in maceration). The external layers of the bone are, as has been already incidentally noticed, much longer than the middle one; they curve inwards toward each other, and are tipped with cartilage. The sternal *fossa* is large and very distinct The sternal *apophyses* are very large. The coracoid bones are long, strongly formed, and smooth anteriorly; the margin much produced at the superior internal edge, and the ends furnished with long hamuliform processes, extending upwards and downwards. The superior one is attached to the clavicle by the intervention of ligament The upper part of the *os coracoides* is bent upon itself at an angle greater than a right angle. They are larger at their inferior ends, the inner ends being produced and curved forwards. The glenoid cavity of the bone is situated on the exterior posterior part, and is formed by this bone and the *scapula*, about three-fifths of the cavity being formed by the *os coracoides*. Each clavicle is turned downwards, and is broader near the coracoid bone, and tapering to the front, where there is a protuberance formed by the junction of the clavicles: this protuberance does not touch the *sternum*. Posteriorly they give off a flat conical process, which goes down internally to the coracoid bone, and is united to the process situated on the posterior part of the *scapula*, immediately inferior to its head. The *scapula* is remarkably broad and thin; its neck and head rounded. There are three articulating processes in this bone: one with the *furculum*; another with the coracoid bone: and the third with the *humerus*. On comparing the *sternum* and adjacent bones with the *sterna* of some nearly-allied *Birds*, less development of the keel is found in the *Loon*, and less development of the lateral wings in the *Auk*, and more in the *Spheniscus*. The differences are shown by tables given in Mr. Reid's paper.

The *humerus* is much flattened. On its posterior aspect there is a large *foramen*, situated under and occupying the whole of the internal part of its head, which is in form crescentic from before backwards: over the internal and posterior part of it a groove passes. The distal end of the bone has two tubercles for articulation. There are two prominent *trochleæ* on its posterior surface, on which work the two sesamoid bones of the elbow-joint. The form of the larger of these is flattened, and of the smaller trapezoid, with truncated edges.

The *ulna* is very thin and flat, not quite so long as the *humerus*, rounded slightly at its upper extremity, and still less at its lower one. Its head has a cavity, which receives the posterior tubercle of the *humerus*. Immediately inferior to this is a prominence on the posterior margin, to which is attached the ligament of the two sesamoid bones. The superior ulno-radial joint admits of little motion, being composed of a convex and plane surface. Near the distal extremity of the bone there are several rough lines for the attachment of muscles. The distal articulating surfaces are three: one with the *radius* anteriorly, another with the first carpal bone inferiorly, and the third with the second carpal bone posteriorly and obliquely downwards.

The *radius* much resembles the *ulna* in shape. At its head it has two articulations: one superiorly, with the anterior tubercle of the *humerus*; and the other posteriorly, for articulation with the *ulna*. There are likewise two articulations at its distal extremity: posteriorly one for the *ulna*; and inferiorly there is another with the first carpal bone Near its neck is situated a process for the attachment of muscles. On its superior anterior part a groove runs obliquely, from before backwards, and from above downwards. At the distal extremity there is a similar one but running in a contrary direction, that is, from behind forwards.

The first carpal bone has the form of a trapezium, with three articulating surfaces: a superior one for the *radius*; a posterior one for the *ulna*; and an inferior one for the *metacarpus*. The shape of the second carpal bone is triangular, with articulating processes, and a notch on its inferior edge; one anteriorly for the *ulna*, the other inferiorly for the *metacarpus*.

The *metacarpus* is composed of a single bone, formed by the union of two. The anterior of the two metacarpal bones supports two *phalanges* of the first finger, and is twice the size of the posterior one, which supports the single *phalanx* of the second finger. The upper end is crescentic, articulated with the first carpal bone anteriorly, and with the second inferiorly. There is a *sulcus* between the ends of the two bones, at their inferior extremity.

The first *phalanx* of the first finger is a long, broad, and flat bone, tapering gradually from above downwards, united to the *metacarpus* by a flat surface, and connected with the second *phalanx* by a similar articulation. The other *phalanx* is broad and flat, tapering from above downwards. By a similar articulation is attached to the posterior metacarpal bone a *phalanx*, which is flat, long, and tapering from above downwards, superiorly giving off a process which passes upwards for a short distance on the posterior part of the metacarpal bone.

The bones of the *pelvis* are so much shortened behind that they throw the centre of gravity in a perpendicular line with the *vertebræ*. The length of the *ilia* behind the cotyloid cavity is one-third of the length of the body in a *Gull* (*Larus*), one half in the *Loon*, and not quite one-fourth of the length of the trunk in the *Patagonian Penguin*. The sacro-sciatic notch is a complete *foramen*. The pubic bones are long and feeble; they are turned forwards and tipped with cartilage. The cotyloid cavity is a perfect *foramen*, with a large process at its postero-inferior part tipped with cartilage, and articulated with the *trochanter major*. The thyroid *foramen* is not complete, except by the intervention of a ligament which separates it from the *obturator foramen*. As there is no *iliacus internus*, the superior part of the *ilium* extends upwards, and lies close to the ribs.

The *os femoris* is formed as usual, the head being flattened anteriorly, the neck short and thick, the *trochanter major* smooth on its superior posterior surface, and articulated with the process on the *ilium*. Besides the posterior there is also an anterior *linea aspera*. There is a process external to the external condyle, having its inferior surface tipped with cartilage, which acts as a pulley. On its [illegible] external surface there is a sharp edge. The condyles are not much everted.

The shape of the *patella* is peculiar. There are two articulating surfaces posteriorly: one which would form part a large crescent, and which has a prominence for the condyles of the *femur* in its centre; the other, inferior, is likewise crescentic; it is very narrow, and articulated by ligaments to the tubercle of the *tibia*.

The superior surface of the *femur* has a *crista* in its centre, of an ovoid form; the posterior edge truncated. The internal surface is perfectly flat; the oblique slightly marked with a ridge, and looks downwards. There is a groove on the centre of the anterior edge, which also passes obliquely downwards on the external side: these two sides are truncated at their junction.

The *tibia* is nearly twice the length of the *femur*; [illegible] tubercle is elevated above its head, and forms a [illegible] short conical truncated process. On the anterior part the head there is a large groove, deepest at the top, and passing obliquely downwards and inwards; the outer side is here smooth, for articulation with the *fibula*. It has inferiorly two condyles, articulated with the *metatarsus*, having a *foramen* above and between them for the transmission [illegible] tendon, &c.

The *fibula* is in the form of a lengthened cone, and attached to the outer surface of the *tibia*; for about two-thirds of its length it is anchylosed to that bone in[illegible]. It has the usual quantity of surfaces for the attach[illegible] muscles.

There is no *tarsus*.

The *metatarsus* has two articular depressions on it[illegible] terior surface, for the reception of the condyles of the *tibia*. It represents three pulleys for articulation with the *phalanges*. On the inner part of the superior face is situated the metatarsal bone of the first toe, connected by ligaments to the large bone. There is a *fossa* on the superior surface, between the first and second and second and third bones of the *metatarsus*; this gradually decreases in size and increases in depth, till it perforates the bone, and joins the *fossa* on its inferior surface, where, immediately anterior, internal, and inferiorly to the outer depression on its head, there is a large protuberance, forming the inner boundary to a groove. The phalangeal end is formed as in most *Birds*. The first toe, which is the smallest in the foot, has three bones, all of which are flattened, and have simple articulations, the last one having a nail. The metatarsal bone is only connected to the others by muscle; the whole length of the toe is one inch; the second toe has three *phalanges*, the third has four, and there are five belonging to the fourth toe. All are formed as is usual in this class.

The ligaments of the head and trunk are of the usual form.

In addition to these, a ligament arises from the sesamoid bones of the elbow joint, which passes to the external or dorsal side of the *carpus*, where it is tied down; it again passes forwards, and is attached by separate slips to the joint and head of the first part of the *metacarpus* and to the first *phalanx* of the first finger, and is inserted into the second about three lines from its head. The ligaments of the hip-joint are as usual. Besides the usual ligaments of the knee-joint, there is one which arises together with the crucial, and is attached to the *patella*, half way down the central line. The form of the semilunar cartilages is crescentic, with prolonged horns. The ankle-joint has semilunar cartilages of the usual form. There are superior and inferior annular ligaments belonging to the *metatarsus*. In no other instance is there any deviation from the usual form.

There is a very large *bursa* situated within the knee-joint.

The muscles were of a dark red colour, very tough, and having a great deal of cellular membrane amongst them. The *fasciæ* were very thick and strong. In no instance did Mr. Reid observe any tendency to ossification in the tendons. In the tendons of the *perforatus* of the first and second toes there was a sesamoid bone, scarcely equalling in size a mustard seed. (*Zool. Proc.*, 1835.)

The sensations of these curious birds do not seem to be very acute. Sparrman relates that he stumbled over a sleeping one and kicked it some yards without disturbing its rest; and Forster states that he left a number of them apparently lifeless, while he went in pursuit of others; but they afterwards got up and marched off with their usual gravity.

ARRANGEMENT, &c.

Mr. Vigors enters the family of *Alcadæ* by means of the genus *Uria* (GUILLEMOTS), which it contains, as well as *Alca* and *Aptenodytes* of Gmelin. "The latter genus," says Mr. Vigors, 'apparently carries to the extreme the typical character of those groups in which the wings, becoming gradually shorter, and less furnished with feathers, lose at length all their powers of flight, and assume the functions of fins instead of wings, to assist the bird in its progress through the water. The whole of the family before us, united by the form of the foot, is separated into generic groups by the different shape of the bill. And here a beautifully progressive series of affinities is apparent, throughout the whole group. Beginning from the true *Aptenodytes*, we may observe that the bill of that genus is long, rather slender, and somewhat curved; while that of *Catarractes*, Briss., which succeeds, is shorter and more elevated at the ridge; thus leading the way to *Spheniscus*, Briss., where the sides are compressed, and the culmen elevated into a sharp ridge. This structure approaches the form of the same member in the true *Alca* [AUK], in which the sides are still more strongly compressed, and the culmen more elevated. The *Fratercula*, Briss., the well known Puffin of our rocky coasts, following *Alca*, exhibits the extreme of this singular construction; and there cannot be a more interesting subject of contemplation to him who may wish to witness the mode in which nature harmonises her groups, than the gradual change of form that unites the short and elevated bill of this last genus with the long and slender bill of *Aptenodytes*. A similar gradation of affinities between conterminous groups leads us back again to the point from whence we started. Some species of the Linnean *Alca*, which M. Temminck has united under the generic title of *Phaleris*, with bills less elevated at the culmen and more tapering than that of *Fratercula*, lead us gradually to the *Mergulus* of Ray, the *Little Auk* of our volumes. This genus strongly and distinctively separated from both *Alca* and *Uria*, in the former of which groups it has been placed by Linnæus, and in the latter by M. Temminck, may be considered as intermediate between them. It thus brings us to *Uria*, where the pointed and tapering bill, again discernible, reconducts us to *Aptenodytes*." Mr. Vigors, having thus observed that the groups composing the *Alcadæ* are characterised by having no hind toe, passes from them to the *Pelecanidæ* by means of *Aptenodytes*. [PELECANIDÆ.]

Head of Aptenodytes.

Mr. Swainson observes that the hind toe in the penguins and cormorants is placed almost as forward as in the swifts. In the penguin, the tarsus is so short as almost to be confounded with the sole of the foot; and it is probably rested upon the ground for its whole length when the bird walks, just as in the bear and other plantigrade quadrupeds; it is also, he adds, remarkably broad; the hind toe is placed in front, and on the inner margin; but it is so unusually small, that, but for its short but well defined claw, it would not be perceived. This claw is without any vestige of a web, or of a lobe, and is quite disconnected from the others; of the three anterior toes, the middle is the longest, the outer rather less, and the inner the shortest. The whole foot is remarkably flattened, as if to enable the bird to cover a greater breadth of ground. (*Classification of Birds*, vol. i.)

Foot of Aptenodytes.

In the second volume of the same work, the author, after a summary discussion of the family *Alcadæ*, considers the penguins, on the whole, as the most singular of all aquatic birds, and he states that they clearly point out that nature is about to pass from the birds to the fishes.

We own that this is not quite so clear to us. Among the terrestrial birds we regard the *Struthionidæ* as presenting the most erpetoid form; and an examination of the organization of the penguins leads us to the conclusion that they more satisfactorily represent some of the aquatic reptiles, especially the marine *Testudinata*. M. Lesson thinks that *Apt. Pachyrhynchus* leads to the mammifers by *Ornithorhynchus*. The *Alcadæ* of Mr. Swainson consist of the genera *Uria*, *Alca*, *Mormon*, *Chimerina* (Eschl.), *Phaleris*, and *Aptenodytes*. The family is placed between the *Colymbidæ* and the *Pelecanidæ*.

According to Mr. G. R. Gray, the genera of the *Alcadæ* are subdivided into the subfamilies *Alcanæ*, *Phalerinæ*, *Spheniscinæ*, and *Urianæ*.

The *Spheniscinæ* comprehend the genera *Spheniscus*, Briss.; *Eudyptes*, Vieill.; *Pygoscelis*, Wagler; and *Aptenodytes*, Forst. (*List of the Genera of Birds*, 1840.) Specimens of each of these genera are to be seen in the British Museum.

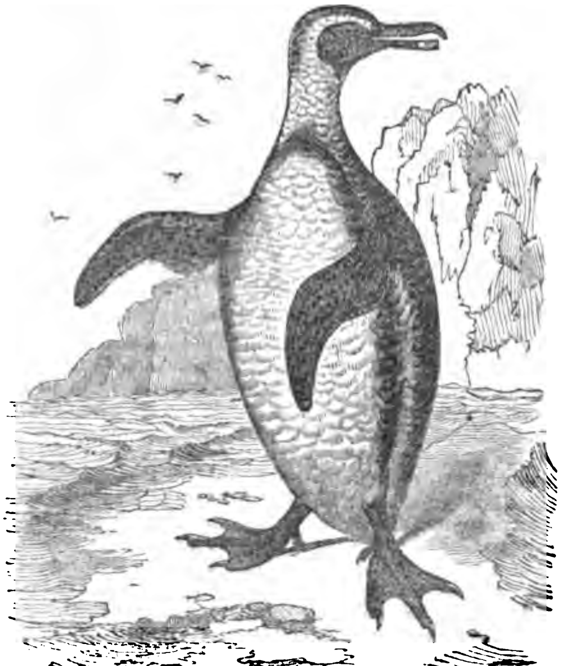
Spheniscus. (Briss.)

Generic Character.—Bill compressed, straight, irregularly furrowed at the base; end of the upper mandible hooked, that of the lower mandible truncated; *nostrils* median and exposed. Wings improper for flight.

Example, *Spheniscus demersus—Aptenodytes demersa*, Gm.

Description.—Bill and *feet* black; the former with a yellowish transverse band near the apex; eye brows and pectoral band white; body above black or black-speckled; white beneath.

Geographical Distribution.—The South Seas, Atlantic and Antarctic. In great abundance at the Falkland Islands and Cape of Good Hope.



Spheniscus demersus.

Eudyptes, Vieill. (Catarrhactes, Briss.)

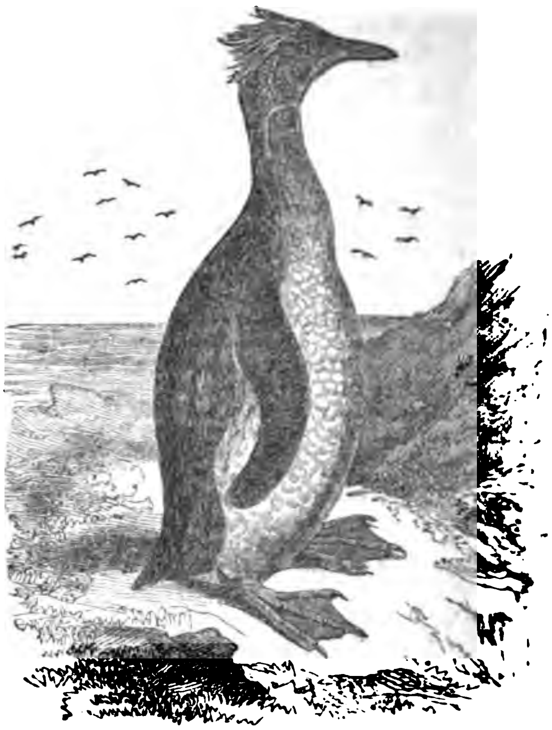
Generic Character.—Bill straight at the base, compressed, furrowed obliquely, pointed, rounded above, upper mandible hooked, lower mandible rounded or truncated at the point; a furrow originates from the nostril and terminates at the lower third of the border. *Wings* reduced to rudiments, improper for flight.

Example, *Eudyptes Chrysocome—Aptenodytes Chrysocome*, Gm.

Description.—Bill reddish-brown; frontal crest, consisting of very narrow loose feathers, black and erectile; auricular band deflected, sulphureous. *Body*, above bluish-black, below velvety-white; *wings* black above, white below; *feet* yellowish.

This is the *Crested Penguin* of Latham; *Manchot Sauteur* of Bougainville and Buffon.

M. Lesson has given a good account of its habits, as well as of those of others of the species, in the *Zoologie de la Coquille*. He states that it lives in all the seas of the southern hemisphere, far from the land; for he killed individuals in 43° 8′ 38″ S. lat. and 56° 56′ 49″ W. long., voyaging in couples, doubtless male and female.



Eudyptes Chrysocome.

Aptenodytes. (Forster.)

Generic Character.—Bill longer than the head, slender, straight, bent at the point: both mandibles equally pointed, rather obtuse; the upper mandible furrowed throughout its length; the lower mandible largest at the base, and covered with a naked smooth skin. *nostrils* linear, hidden by the frontal feathers. *Feet* short and stout; toes directed forwards, great toe very short. *Wings* featherless, reduced to rudiments or winglets covered with hairy feathers.

Example, *Aptenodytes Patachonica*.

Aptenodytes Patachonica.

Description.—Lower half of the demi-bill red; head and throat covered with very black feathers; a yellow orange band, widest towards the occiput, occupies each side, unite upon the breast, and separate the black of the throat from the grey-ash which covers the back; the feathers of the belly have the whiteness and lustre of satin, and a yellow tint more and more deepened mingles in it towards the upper part of the breast; two bands of deep black occupy the sides; toes strong and robust; wings more elongated than in the other penguins. Height, when erect, upwards of three feet.

Geographical Distribution.—Southern hemisphere in high latitudes. Straits of Magalhaens; Falkland Islands, Antarctic Islands, &c. Weddell (*Voyage to the South Pole*) gives a highly interesting account of the habits of this species.

The forms above given will, it is hoped, sufficiently explain to the student the group before us. The type of the genus *Pygoscelis* of Wagler is *Aptenodytes Papua* of Gmelin, an inhabitant of Papua, or New Guinea, among other localities.

PENICILLUS, a subdivision of the Linnæan genus *Corallina*. [illegible]

PENICILLUS, Bruguière's name for the Aspergillum of Lam. [ASPERGILLUM; TUBICOLIDÆ.]

PENITENTIARIES. [PRISONS.]

PENITENTS. [PENANCE.]

PENJAB, or **PANJAB**. [HINDUSTAN.]

PENKRIDGE. [STAFFORDSHIRE.]

PENMAEN MAWR. [CAERNARVONSHIRE.]

PENN, SIR WILLIAM, was born in 1621, at Bristol. Having entered into the sea-service, he was made a captain in 1642, and an admiral in 1653 for his services against the Dutch. He was one of those who commanded when Jamaica was taken from the Spaniards in 1655, in which year he returned to England, and was elected member of parliament for Weymouth, but was committed to the Tower by the republican government on the charge of having left his command without leave. After the Restoration he was created a knight, and was made a commissioner of the navy, governor of Kinsale, and a vice-admiral. He again went to sea in 1664, and was commander-in-chief under the duke of York, in the naval victory over the Dutch in 1665. In 1666 he retired from service at sea, but continued to perform his other duties till 1669, when he went into retirement at Wanstead in Essex, where he died in 1670.

PENN, WILLIAM, the only son of Admiral Penn, was born in London, October 14, 1644. He was educated with much care at Chigwell in Essex, and then at a private academy in London. In 1660, he was entered a gentleman commoner of Christ Church, Oxford. His first bias towards the doctrines of the Society of Friends, or Quakers, as they are commonly called, appears to have been produced by the preaching of Thomas Loe; the effect of which was, that, while at Oxford, Penn, together with some of his fellow-students, began to withdraw from attendance on the public worship of the established church, and to hold private prayer-meetings. They were fined by the college for nonconformity, but this did not deter them; for, an order from the king having required that the antient custom of wearing surplices should be revived, Penn and his associates attempted to tear them from the backs of those students who wore them. For this display of intemperate zeal they were expelled from the college.

Admiral Penn, who was in high favour with Charles II. and the duke of York, and ambitious for his son's advancement at court, was much displeased with this event, and still more with the change which had taken place in his son's manners. He tried to turn him from his religious observances and company, but in vain, and at length was so highly incensed as to have recourse to blows, and finally turned him out of doors. The admiral soon relented so far as to try another expedient. He sent him, in 1662, on a tour to France. After remaining a considerable time in Paris, Penn went to Saumur, and studied under the popular preacher Moses Amyrault. He afterwards proceeded to Turin, whence he was recalled by his father to England, in 1664, who, on his return, was greatly pleased with the polish and courtliness of manners which he had acquired. He was now admitted a student of Lincoln's Inn, where he continued till 1666, when his father sent him to Ireland, for the purpose of managing his estates in that country. This duty he performed to the entire satisfaction of his father; but, happening to attend a religious meeting at Cork, where Thomas Loe delivered a discourse, beginning 'There is a faith that overcomes the world, and there is a faith that is overcome by the world,' he was so deeply impressed, that from this time he constantly attended the Quakers' meetings. At one of these, held at Cork, in 1667, he and others were apprehended by order of the mayor, who would have set Penn at liberty on his giving bail for his good behaviour, but he refused, and was sent to prison with the rest. He wrote however to the earl of Orrery, then lord president of Munster, requiring the release of all, but the earl contented himself with ordering Penn alone to be set at liberty.

Admiral Penn, on being informed that William had decidedly joined the Quakers, summoned him home, and remonstrated with him and threatened him, but in vain: the son was firm, but respectful. The admiral at last restricted himself to the demand, that he should take off his hat in the presence of the king, the duke of York, and himself. But Penn refused to pay even this limited degree of 'hat worship,' at which the admiral was so much incensed that he again turned his son out of doors; but in a short time he allowed him to return home.

In 1668 Penn began to preach, and also published his first work, 'Truth exalted.' In this year a preacher named Vincent accused the Quakers of being opposed to the doctrine of the Trinity. A public disputation took place, from which both parties retired without being convinced. In prosecution of this controversy Penn wrote 'The Sandy Foundation shaken,' in which he professed his belief in the doctrine of the Trinity, but objected to the language in which it was expounded by the church of England; and for this he was committed to the Tower. During his imprisonment, which lasted nearly seven months, he wrote his 'No Cross, no Crown,' one of his most popular works. In 1669, after his liberation, an entire reconciliation took place between him and his father, and he again went to Ireland to look after his father's estates, in which country he remained about twelve months.

In 1670 the Conventicle Act was passed, and Penn was one of the first sufferers under it. He was committed to Newgate for preaching to what was called 'a riotous and seditious assembly,' which consisted of the Quakers, who had been excluded from their chapel, and who now met in the open street, as near to it as they could. The trial took place at the Old Bailey Sessions, and is remarkable not only for the firmness and ability of Penn's defence, but for the admirable courage and constancy with which the jury, in opposition to the direction of the Bench, and in defiance of its threats, pronounced a verdict of acquittal. The jury were fined, and ordered to be imprisoned till the fines were paid; but this proceeding was declared illegal by the Court of Common Pleas, on which occasion, chief-justice Vaughan delivered an able speech in defence of the rights of juries. Soon after this Admiral Penn died, perfectly reconciled to his son, to whom he left estates worth 1500*l*. a year. In February, 1670-1, Penn was again committed to Newgate on a charge of preaching publicly, and he remained in prison six months.

In 1672 Penn married Gulielma Maria, daughter of Sir William Springett, who was killed in the civil wars at the siege of Bamber. He now took up his abode at Rickmansworth in Hertfordshire, but afterwards settled at Worminghurst in Sussex.

In 1677, in company with George Fox and Robert Barclay, he made a sort of religious tour in Holland and Germany, and was received with marked distinction by the princess Elizabeth of the Rhine, daughter of the king of Bohemia, and granddaughter of James I. of England. After his return, he was heard before a committee of the House of Commons in behalf of the Quakers, who were oppressed by Exchequer prosecutions under statutes which had been enacted against the Roman Catholics; he was also admitted to plead before a committee of the house, that the solemn affirmation of the Quakers should be admitted in the place of an oath, and to this effect an enactment passed the Commons in 1678, but was lost, in consequence of a prorogation, before it had passed the Lords.

We now come to an important event in Penn's life, the establishment of the colony of Pennsylvania. A tract of country on the west side of the Delaware was granted on petition by Charles II. to Penn and his heirs, in consideration of a debt of 16,000*l*. due from the crown to Admiral Penn, for money advanced for the service of the navy. To this the duke of York added by cession a contiguous portion of territory lower down on the Delaware. The king's patent was dated March 4, 1680-1, and in this document he named the province, in honour of the founder and his father, Pennsylvania. Penn was constituted absolute proprietor and governor of the province. He published 'Some Account of Pennsylvania,' &c., and also 'Certain Conditions or Concessions, &c., in which he offered easy terms of settlement to those who might be disposed to emigrate. Three ships soon set sail with settlers from England and Wales, chiefly Quakers. In the beginning of 1682 he published 'The Frame of the Government of the Province of Pennsylvania in America, together with certain Laws agreed upon in England by the Governor and divers Freemen of the aforesaid Province, to be further explained and confirmed there by the first Provincial Council that shall be held.' Having previously opened a friendly intercourse with the native Americans by presents and conciliatory letters, in the autumn of 1682 he sailed for Pennsylvania, leaving his wife and children in England, and soon after his arrival summoned an assembly of the freemen of the province, by whom the frame of government, as formed in England, was accepted. He had sent out instructions, before he left England, to negotiate a treaty of sale with the Indian nations, and tradition records that a great meeting of the Indian nations and European settlers took place under an enormous elm-tree, near the site of Philadelphia, when the treaty was ratified, and a league of friendship established, 'a friendship,' says Proud, the historian of Pennsylvania, 'which, for the space of more than seventy years was never interrupted, or so long as the Quakers retained power in the government.' The exact date of this memorable assembly has not been specified.

Having founded the city of Philadelphia on the banks of the Delaware [PHILADELPHIA], and spent about two years in the province adjusting its political constitution, and bringing the colony into a state of prosperity and order, he returned to England about Midsummer, 1684. Within this short period no less than fifty sail arrived in the province with settlers from England, Ireland, Wales, Holland, and Germany.

In February, 1685, soon after Penn's return to England, Charles II. died, and the favour with which James II., when duke of York, had regarded Admiral Penn, was transferred to his son. After the Revolution in 1688, his intimacy with James II. exposed him to suspicions, and he was four times arrested on accusations of being a concealed Papist and a Jesuit; but he always cleared himself before the king and council, till one Fuller, who was afterwards declared by parliament to be an impostor, in 1690 accused him on oath of being concerned in a plot to restore the late king. Unwilling to expose himself to the risk of being convicted upon the oath of such a man, and the perjured evidence which he might get up, he lived in great seclusion in London till 1693, in which year, through the mediation of his friends at court, he was admitted to plead his cause before the king and council, and was honourably acquitted. Soon after this his wife died. In 1696 he married Hannah, the daughter of Thomas Callowhill, a merchant of Bristol.

In 1699 he again sailed for Pennsylvania, with his wife and family, with the intention of making it the place of his future residence. He had been deprived of the government of Pennsylvania in 1692, and it had been annexed to that of New York; but it was restored to him in 1694 by an instrument of William and Mary. An attempt was afterwards made to take possession of the proprietory governments in North America, and to convert them into regal ones. A bill for this purpose was already before the lords, when it was delayed by petition of the friends of Penn, who immediately embarked for England, where he arrived in December, 1701. The bill was dropped after his return, and the accession of Queen Anne once more restored him to favour at court. In the meantime Penn had become encumbered with debt. He had mortgaged Pennsylvania in 1708 for 6600*l*. In 1712 he agreed to sell his rights to the English government for 12,000*l*., but was unable to complete the transaction by three apoplectic fits which followed each other in rapid succession, and considerably impaired both his memory and understanding. He survived however in a tranquil state, though with his bodily and mental vigour gradually decaying, till the 30th of July, 1718, when he died, at his seat at Ruscombe in Berkshire.

Penn left children by both of his wives, and to them he bequeathed his property in Great Britain and America. The government and quit-rents of Pennsylvania devolved to the surviving sons of the second family, with the title of Proprietaries, and by them were sold to the state of Pennsylvania, after the American Revolution, for 130,000*l*.

Penn's writings, which are numerous, were collected, and published, with a Life prefixed to them, in 1728, 2 vols. folio.

(Clarkson's *Life of Penn*; Sewell's *History of the Quakers*; Proud's *History of Pennsylvania*.)

PENN-AIR. [HINDUSTAN, vol. xii., p. 208.]

PENNANT, THOMAS, was born of an antient Welsh family, at Downing in Flintshire, on the 14th of Jan., 1726. He was educated at Wrexham school and subsequently at Oxford, but took no degree in that university, though the honorary distinction of LL.D. was afterwards conferred on him. When about twelve years old he received a present of Willughby's 'Ornithology,' and he dated the commencement of that fondness for natural history which distinguished his future life from the perusal of this book. Immediately after leaving Oxford he made an excursion into Cornwall for the purpose of examining the mines and investigating the objects of natural history which that county possesses. His first literary production was an account of the shock of an earthquake felt at Downing in 1750, which was published in the 'Philosophical Transactions.' In 1756 a memoir appeared by Pennant in the same work, on certain coralloid bodies found in Shropshire; this attracted the attention of Linnæus, upon whose recommendation the author was elected a member of the Royal Society of Upsal, a distinction of which Pennant was always particularly proud.

In 1761 he commenced the publication of his first great work, the 'British Zoology,' which was printed in large folio, and when complete contained 132 plates. It afterwards went through many smaller editions, and received numerous additions. Latin and German translations with the plates were published abroad. The best copies of the work are those which came out in 4to. in 1776 and 1777, in 4 volumes. The 'British Zoology' included nearly the whole of the species of the animal kingdom (at that time known) inhabiting this island, with the exception of the class of insects, which was entirely omitted. In 1765, during the progress of this work, Pennant made a tour on the Continent, where he was introduced to some of the celebrated foreign naturalists. He visited Buffon at Montbard, and he afterwards maintained a correspondence with this great man. From France he proceeded to Switzerland, and at Berne became acquainted with Baron Haller. He then travelled through Germany and Holland, and formed an intimacy at the Hague with Pallas. Speaking of this naturalist, Pennant says, 'Our conversation rolled chiefly on natural history, and as we were both enthusiastic admirers of the great Ray, I proposed his undertaking a history of quadrupeds on the system of our illustrious countryman, a little reformed. He assented to my plan, and wrote me a long letter in which he sent an outline of his design, and his resolution to pursue it with all the expedition consistent with his other engagments.' Pallas went to Russia, and never accomplished this project, but Pennant followed up the idea himself, and in 1771 published a work with the title of a 'Synopsis of Quadrupeds,' illustrated with about thirty plates. This was intended as a sort of index to the species of animals described by Buffon in his great work on natural history; he gradually however extended its limits, and included in it the description of many animals which he had observed in different collections, or which had been discovered by different travellers, and were unknown to Buffon. He followed the arrangement which had been conceived by Ray, introducing however the genera established by Linnæus. The 'Synopsis,' when enlarged, was republished with the name of a 'History of Quadrupeds.' The descriptions in this work were short and meagre, and the synonymes few in number and not always correct; nevertheless it was very well received, for it was the first [illegible] work on quadrupeds in which they were methodically arranged, and it contained a number of new species and many original figures, which were correctly though not very elegantly drawn. It went through several editions, and Buffon availed himself of the matter contained in it for his supplements. Cuvier says of this work, 'that it is still indispensable to those who wish to study the history of quadrupeds.' After his return to England, Pennant commenced a work on 'Indian Zoology,' of which 15 folio plates were published, the expense of which was partly defrayed by Sir Joseph Banks: it was soon discontinued.

In 1769 he set out on a tour through Scotland, the northern part of which had at that time been little explored by the traveller or the naturalist. He kept a journal which he noted down all the objects of interest that he met with, and published it after his return, with plates illustrating the scenery, &c.; this work went through many editions. He made a second excursion into Scotland in 1772, of which he also published an account. He was accompanied in this tour by Dr. Lightfoot, who then collected a great part of the materials for his 'Flora Scotica,' in the preparation of which Mr. Pennant was of great assistance to him.

The next work which Pennant commenced was a systematic catalogue called the 'Genera of Birds;' this was intended to be similar in plan to the 'Synopsis of Quadrupeds,' but it was never completed. His last great work was his 'Arctic Zoology,' which appeared in three quarto volumes in 1784-85-87, and contained twenty-six plates. This (which was necessarily a compilation, as the author never visited the native haunts of the animals which he described) included an account of the northern coasts of Europe, Asia, and America, with their productions, taken from the writings of different travellers, and from the examination of specimens of different animals sent to the author or preserved in museums. Pennant received considerable assistance during the progress of this work from many foreign naturalists, among whom Pallas, Thunberg, Sparman, Müller, and Fabricius may be mentioned. The 'Arctic Zoology' acquired considerable reputation among naturalists, and was valuable from containing descriptions and figures of many animals and birds previously unknown. It is universally consulted and referred to by authors at the present day.

When in his sixty-seventh year, he planned an extensive work on the model of the preceding, which was to embrace an account of every country in the world, with their productions; he published two volumes of this, in 4to., entitled a 'View of Hindostan.' Two more were brought out by his son, after his decease, with the name of 'Outlines of the Globe,' which also include the description of India and the adjoining countries.

Pennant wrote, among several other works, a 'Journey from Chester to London,' a 'History of London,' and a 'Tour in Wales,' which contain much interesting matter on antiquities and natural history. He never followed any profession, but spent almost the whole of his life as a retired country gentleman at his seat of Downing, in the midst of his favourite pursuits. He enjoyed nearly uninterrupted health till within a few years of his death, which took place in 1798.

PENNATULA. [PENNATULARIA.]

PENNATULA'RIA, a family of Zoophyta. The Linnæan genus Pennatula included several species of compound Zoophyta, having an internal elongate axis. Lamarck divided them into seven genera, and constituted for them a grand section of the Polypiaria, under the title of *Polypi natantes*, or *Floating Corallines*. One of these genera is Encrinus, which belongs to a very different group of animals. (*Animaux sans Vertèbres*, tom. ii.) Cuvier, avoiding this great error, employs eight generic distinctions. (*Règne Animal*, 2nd ed., tom. iii., p. 317.)

Blainville (*Actinologie*, p. 512) places the family of Pennatularia in his class Zoophytaria, and employs six genera, of which five were instituted by Lamarck and one by Cuvier.

The following are the characters of the group, according to Blainville:—

Animals polypiform, provided with eight pinnated tentacula, more or less prominent, and regularly scattered on the surface of one part of the general substance. The form of the whole is determinate; the mass is composed of a central solid axis, surrounded by a fleshy substance (analogous to the bark of a tree), often very thick, and supported by calcareous aciculæ more or less numerous.

All or nearly all of these animals are unattached, and float in the waters of the sea. Some writers have conjectured that in their movements the numerous polypi of the mass obey a common will. Phosphorescence belongs to several in a living state.

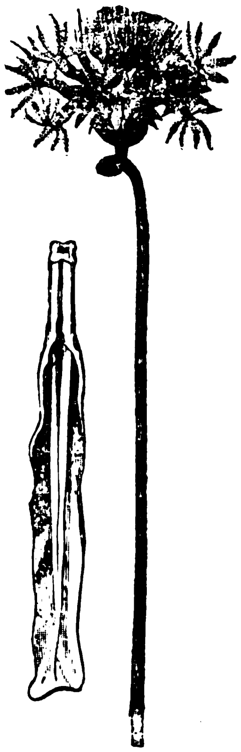
Whatever be the general form of the species of Pennatularia, one of the extremities is always devoid of polypi: in Pennatula this part may be compared to the tubular part of a feather, while the polypiferous portion resembles expanded barbs. There is therefore in these Polypiaria a bilateral symmetry which is not distinctly observed in other groups.

GENERA.

Umbellularia.

Animals polypiform, elongated, subcylindrical, provided with eight tentacula strongly pinnated, united into an umbel, in small number, at the end of a regular tetragonal cortical mass, which contains a long internal, tetragonal, calcareous axis.

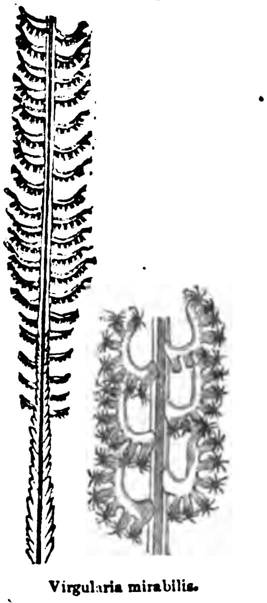
One species, the Vorticella encrinus of Ellis, figured in his work on the Corallines, p. 86, tab. 37, was found in the Greenland Seas; another (Umbellaria stellifera, Gmelin) is mentioned in Müller's 'Zoologia Danica,' p. 133, tab. 35. Example, *Umbellularia encrinus.*



Umbellularia encrinus.

Virgularia.

Animals polypiform, with eight ciliated tentacula, disposed in rows, on one edge of small oblique pinnules, which occupy the posterior extremity of a common cylindric almost linear mass, and are not spinous.



Virgularia mirabilis.

By this latter character, the arrangement of its pinnules, and the linearity of its rachis, Virgularia differs from Pennatula. It is not easy to say how many species are really known. Lamarck gives three, which Blainville adopts, but Cuvier reduces them to two. They are from European and Indian seas.

Example, *Virgularia mirabilis* (Pennatula mirabilis of Müller). Blainville, tab. 90, f. 5, 5 a.

Pavonaria.

Animals polypiform, sessile, not retractile, provided with eight pinnated tentacula, disposed in quincunx on one face of the retral half of a free, regular, elongated, quadrangular rachis.

A genus of Cuvier, adopted by Blainville. Both authors agree in referring to it two species described by Bohadsch and Pallas.

(There is extreme confusion of synonymy in the references to figures of Pennatularia, and particularly to Pennatula mirabilis, a term apparently given to different objects by Linnæus, Pallas, and Müller.)

Pennatula mirabilis of Linnæus is referred by Cuvier to his genus Scirpearia.

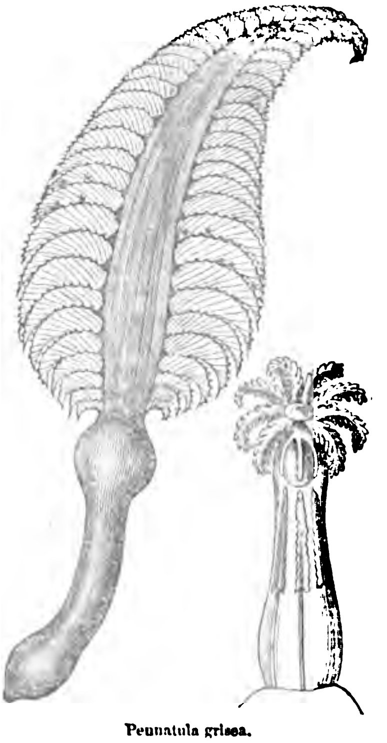
Pennatula.

Animals polypiform, provided with eight pectinated tentacula entirely retractile, and irregularly disposed on the retral edge of a sort of spears or lateral pinnules; these pinnules are symmetrically placed along the whole extent of a regular, symmetrical, spiculiferous rachis, and they are prolonged into a bulbiform expansion pierced by four terminal openings.

The general form is sufficiently that of an expanded feather to justify the name.

Blainville admits four species, all but one from European seas. M. Ehrenberg thinks there are five.

Example, *Pennatula grisea*, Gmelin. (Blainville's *Actinologie*, tab. 89, figs. 1, 16.)



Pennatula grisea.

Veretillum.

Animals polypiform, cylindrical, furnished with eight pinnated tentacula, and retractile into orifices scattered in the substance of a regular, cylindrical, obtuse, unbranched, mostly fleshy rachis, which is prolonged into a bulbiform expansion pierced with four terminal openings. The internal solid axis is very small.

Cuvier established the genus, and remarks that in the large polypi of Veretillum the prolongation of the intestine into the common stem is more easily followed than in other compound Zoophyta.

Cuvier gives three species; Lamarck and Blainville two. Veretillum cynomorium, a foot long and an inch in diameter, occurs in the Mediterranean, and is remarkable for the vividness of the light which it diffuses around.

Renilla.

Animals polypiform, provided with eight pinnated tentacula; rachis dilated from a cylindrical free pedicle into a broad reniform expansion, on one face of which the polypi are scattered.

Pallas states that Pennatula reniformis (Renilla Americana), the type of the genus, has only six tentacula; but Schweigger describes eight. There is another species (Renilla violacea), noticed by Quoy and Gaimard, from Australasia.

Some of the singular fossil bodies known to geologists since the days of Linnæus by the title of Graptolithus are supposed by Nillson, Dr. Beck, and others to belong to the family of Pennatularia.

PENNI, GIOVANNI FRANCESCO, called Il Fattore, was born at Florence, in 1488, and received the name Il Fattore, or the Steward, from his having been entrusted with the management of the domestic affairs of Raphael. He however soon became one of his principal assistants. Dr. Waagen is of opinion that Penni executed many parts of the cartoons at Hampton Court, especially those of the Death of Ananias, St. Paul and Barnabas at Lystra, and St. Paul preaching at Athens. Of Penni's own works, frescoes and very few oil paintings remain. His characteristics are said to have been facility of invention, graceful execution, and singular felicity in landscape. After the death of Raphael, Penni went to Naples, where his works would doubtless have contributed to improve the prevailing style, had he not been cut off in 1528, at the age of 4

PENNSYLVA'NIA, one of the United States of North America, and one of the most important in magnitude, population, and industry. It extends from 39° 43′ to 42° N. lat., and from 74° 50′ to 80° 30′ W. long. It is separated on the east from New York and New Jersey by the winding course of the Delaware river, which constitutes the boundary for 230 miles. On the north it borders on New York, which is separated from it by the parallel of 42°, with the exception of the most western part, where Pennsylvania passes north of that line and reaches to the shores of Lake Erie. This lake washes the boundary for about 39 miles. The western boundary runs along the meridian of 80° which separates it from Ohio and Virginia for 155 miles. The parallel of 39° 43′ constitutes its southern border for 260 miles, dividing it from Virginia and Maryland. Pennsylvania is divided from the state of Delaware by a curved line about 24 miles long. Its mean length from east to west is nearly 300 miles, and its mean width 158 miles. The surface is estimated to be 47,000 square miles, or about 3000 miles less than that of England.

Surface and Soil; Climate and Agricultural Productions.—The Appalachian Mountains cover more than one half of the surface of this state. Along the southern boundary-line, between Mercersburg on the east and Union the west, the width of these mountains hardly falls short of 100 miles. The ridges of which the mountain-system consists run in the general direction of the whole system, south-south-west and north-north-east. North of 41° N. lat. the eastern ridges turn to the east-north-east, and continue in that direction to the banks of the Delaware, and the western ranges continue in a north-north-east course to the northern boundary of the state. Thus it happens that between 41° and 42° N. lat. the two outer ridges of the mountains are 200 miles apart. This mountain region occupies the middle of the state, and to the south-east and north-west of it extend two hilly regions exhibiting different natural features. The south-eastern region is estimated to occupy a surface of 7869 square miles; whilst the mountain region covers 25,189, and the north-western 13, square miles.

I. *The South-Eastern Region* extends along the Delaware river as far north as Williamsburg (near 41° N. lat.), and along the boundary of Maryland as far west as Mercersburg in Franklin county. Its north-western border is formed by the eastern ridge of the mountains called the North Mountains or Blue Mountains. The surface rises gradually from the south-east to the north-west, and near the foot of the Blue Mountains attains an elevation of between 200 and feet above the sea. It is not level and flat, but a continual ascent and descent. About 15 miles from the Blue Mountains, the hills form a continuous ridge, which rises to a considerable height near the southern boundary, but farther east exhibits frequent depressions and appears only in broken ridges. This ridge, which is called the South Mountain, terminates on the banks of the Delaware at the mouth of the Lehigh river. The country along the Delaware has an undulating surface, rising in low and gentle swells. The soil of this tract is a sandy loam, not distinguished by fertility, but well cultivated on account of the ready market afforded by the navigable river and the city of Philadelphia. About 30 or 40 miles from the river, the hills rise higher and their sides are rather steep, but the soil improves considerably in fertility, especially in the vicinity of the South Mountain, which is perhaps the most fertile district in the state. The country between the South Mountain and the Blue Mountains is very little inferior in fertility, especially the district which extends between the Schuylkill and Susquehanna rivers and Cumberland Valley. Its surface is rather hilly than undulating.

The climate of this region resembles that of England, except that the changes are more sudden and greater, and the summers hotter and the winters colder, than in England. The mean annual temperature seems to vary between 51° and 53° according to the elevation of the country. According to meteorological observations continued for nine years, the mean annual temperature of Germantown, near Philadelphia, is 53° 37′ Fahr.; that of London is 50° 5′. The mean temperature of the winter in Germantown is 32° 23′, and in London 39° 8′; that of the spring in Germantown 50° 2′, and in London 51° 1′. In summer it rises in the first place to 71°, and in London to 61° 2′; in autumn it is 52° 8′ in Germantown, and 51° in London. During the greatest cold experienced in this period, the thermometer descended in Germantown to 10° Fahr., and during the greatest heat it rose to 95°. During the winter months there is a good deal of frost and snow. When the wind has blown for a time from the south-east, and suddenly turns to the north-east and north-west, a difference of temperature amounting to twenty degrees is not uncommon. Such changes occur also in summer, when a difference of from 20 to 30 degrees is frequently observed between the afternoon and the following morning, especially after storms of rain and thunder. The most agreeable months are April, May, the first half of June, September, and a part of October. Westerly, north-westerly, and south-westerly winds are by far the most frequent, and heavy gales are far from being rare. Rain is abundant all the year round. The mean annual fall is 36 inches. The greatest quantity falls in the summer months, from June to September, both included; in July it sometimes amounts to 8 or 9 inches.

In this region are cultivated the grains of England, with Indian corn and much buckwheat. Hemp, flax, tobacco, and esculent plants thrive very well. The orchards chiefly produce apples, peaches, and cherries; the other fruits are less cultivated. In some sheltered places there are extensive vineyards.

II. *The Mountain Region* presents a different aspect in the southern and in the northern districts. South of 41° N. lat. it consists of a succession of steep ridges and narrow valleys, but north of that line it extends in an elevated table-land, the greater portion of the surface being occupied by large tracts of level or hilly ground, while the mountain-ridges are far distant from each other and cover a comparatively small part of the surface.

Nearly in the middle of the mountain region runs the highest and widest of the ranges of which it is composed. This range is called the Allegheny mountains, a term which is often applied to the whole mountain-system of the Appalachians. In the southern districts of Pennsylvania it forms the watershed between the rivers which descend eastward to the Potomac and Susquehanna, and westward to the Ohio; but north of 41° N. lat., where it inclines to the north-east, the continuity is broken by the upper branches of the Susquehanna. The summit of this range is broad and nearly of equal elevation, being destitute of peaks. Its elevation above the sea, south of 41°, seems to vary between 2000 and 2400 or 2500 feet, and it stands on a base from 800 to 1000 feet high, and from 8 to 10 miles wide. East of the Allegheny mountains there are five or six other ridges running parallel to each other; they attain a much less elevation, hardly more than 1200 feet above the sea-level. The most eastern of these ridges, the Blue Mountains or North Mountains, seems to be the highest, and, at the Wind Gap, near Williamsburg on the Delaware, attains the elevation of 1200 feet. The valleys enclosed by these several ridges rise in elevation as they approach the Allegheny mountains, the most easterly being hardly more than 200 feet above the sea-level, whilst those immediately contiguous to the base of the Allegheny mountains are 800 feet. Both the ridges and the valleys are comparatively narrow, occupying on an average only three miles in width. The declivities of the ridges are steep and the valleys much depressed and deep. The mountain-region west of the Allegheny mountains, south of 41° N. lat., consists of two broad valleys and two mountain-ranges, the Laurel Hills and the Chestnut Ridge. The valleys are about 1000 feet above the sea-level, and the ranges attain nearly the elevation of the Allegheny mountains, probably 2000 feet above the sea-level. The soil of this region is in general poor and stony, though the valleys contain some alluvial tracts of great fertility, but of inconsiderable extent.

No meteorological observations have been made in this region. The winters are very cold and of long duration; the snow covers the ground for several months; the springs are wet, and the summers, though hot, of comparatively short duration. Indian corn does not ripen in most parts, and is only planted to be consumed before it gets ripe; wheat is only cultivated in sheltered places. The most common grains are rye and oats. Orchards are not numerous, but apples thrive very well. The vegetables generally raised are peas, parsnips, carrots, onions, shallots, potatoes, sweet potatoes, and cabbages. The uncultivated portion of this region, which comprehends perhaps nine-tenths of the whole, is chiefly covered with forests. On the higher parts of the ridges the mountains are covered with conifers, as pitch, spruce, and white pines and cedars. In many parts they attain the height of full-grown timber-trees, but in others, where the sides of the hills have been washed by heavy rains and the soil is stony and poor, they are only of scrubby growth. The most common trees in the valleys are oak and chestnut, and, where the soil is subject to inundation, sycamore. West of the Laurel Hills, the forests are mainly composed of the broad-leaved laurel, rhododendron, and magnolia acuminata, mixed with chestnut-trees and some oaks.

The table-land of Pennsylvania, or the mountain region north of 41° N. lat., consists, as already observed, of large plains and some ridges. The plains have usually a broken and sometimes a hilly surface, and are partly covered with trees. Some level plains are large swamps. The highest part of the table-land is contiguous to the boundary-line of New York, and rises to an elevation of between 1200 and 1500 feet. The few ridges with which it is over-topped are a few hundred feet higher. Along the watercourses the table-land is depressed, sometimes eleven hundred feet, and in these districts wheat, rye, oats, and some vegetables are cultivated. There are however extensive pastures on the higher parts. The climate is still more severe than it is between the ridges farther south, as the low ridges cannot shelter the plains against the prevailing north-west winds. The forests of the higher land are almost entirely composed of conifers, but they do not contain many timber-trees, the stony soil being too poor for their growth. In the depressions and along the rivers are sugar-maple, black walnut, elm, and beech.

III. *The North-Western Region* is divided from the mountain-region by Chestnut Ridge, whose northern prolongation divides the waters which run east to the Susquehanna and west to the Allegheny river. It constitutes the most eastern portion of the inclined plain which extends from the base of the Appalachian mountains westward to the banks of the Mississippi. Near the foot of the mountain it is from 900 to 1000 feet above the sea, and where it approaches the boundary-line of Ohio it is still nearly 700 feet above it, in the valley of the Ohio, but much higher farther northward, where it preserves the elevation of from 900 to 1000 feet to the very boundary-line. The surface of this region is undulating, the ascents being gentle and the upper part of the eminences broad, with a rounded outline, except along the watercourses of the larger rivers, where the ascent is rather steep. The soil varies very much. In many places there are large tracts with a poor and stony soil; in others, especially along the rivers, there are fertile tracts. The climate does not materially differ from that of the south-eastern region, except that the winters are colder, as may be inferred from the greater elevation of the country, and its exposure to the northern and north-western winds; the quantity of rain which falls is not quite so great. In the southern districts (south of 41° N. lat.) cultivation has made considerable progress, and the country presents a pleasing variety of fields and forests. All the grains of the south-east region are raised in abundance, and the orchards produce great quantities of fruit, especially apples and cherries. The forests consist chiefly of oak and sugar-maple. The northern districts are almost entirely covered with forests, consisting of hemlock, spruce, and Weymouth pine, intermixed with beech, birch, and sugar-maple. The Weymouth pine attains a great size in these districts.

Rivers.—The most important river of Pennsylvania is the Delaware, which is navigable for river boats to a distance of 200 miles from its mouth. [Delaware.] The Susquehanna rises in two branches on the table-lands of Pennsylvania and New York, of which the eastern branch originates near 74° 40′ W. long., and the western near 78° 40′, and consequently more than 200 miles from each other. The eastern branch, which is considered the principal, has its source in Lake Otsego, near the western declivity of the Tuscarora mountains in New York. [New York.] It traverses the table-land of New York in a south-western and western direction, and after a course of about 140 miles it enters Pennsylvania, and soon afterwards is joined by the Tioga river, which collects its waters on the table-land farther west, and flows about 30 miles. From the junction with the Tioga it flows about 50 miles south-east and afterwards about 70 miles south-west to its junction with the great western branch. Thus it runs about 260 miles above this confluence, which takes place a few miles north of Sunbury. The great western branch of the Susquehanna is, in all its extent, exclusively a river of Pennsylvania. It originates in a mountainous tract in which the Laurel Hills are connected with the Chestnut Range, south of 41° N. lat. Issuing from this tract by a northern and north-eastern course of about 50 miles, it flows over the table-land, with great bends mostly in an eastern direction, about 80 miles; it then turns southward and joins the eastern branch above Sunbury, after having run about 25 miles in that direction. This river runs 155 miles above its junction with the eastern branch. After the union of both branches, the Susquehanna runs southward for about 50 miles, traversing by narrow valleys five or six of the ridges, which here lie between the table-land and the south-eastern region. Before it reaches the lower country it is joined by the largest of its affluents, the Juniata, from the west. The Juniata rises on the western declivity of the Alleghany mountains, and runs first southward for about 20 miles; it then turns eastward, and after flowing in that direction about 10 miles more, it runs northward about 40 miles. By this circuitous course it collects by far the greatest part of the waters east of the Alleghany mountains in the mountain-region south of 41° N. lat. It afterwards runs eastwards with many large bends until it joins the Susquehanna about 35 miles below Sunbury, after an entire course of more than 150 miles. After having left the mountain region above Harrisburg, the Susquehanna still flows through a narrow valley formed by the South Mountain, 8 miles below Harrisburg, and before it enters this valley it is joined from the north-east by the Swatara creek, whose course hardly exceeds 50 miles. The course of the Susquehanna through the south-eastern region may be about 150 miles; so that the river flows 200 miles after the junction of its branches near Sunbury. The Susquehanna is not navigable, owing to the rapidity of its current and the numerous rocky ledges which form numerous rapids. The last of these ledges occurs about 20 miles from its mouth in Chesapeake Bay, and so far small vessels may ascend the river. The water of this river however has lately been used in the construction of canals. Some of the affluents of the Susquehanna, as the Tioga, Juniata, and Swatara, are navigable for small boats, at least a considerable part of the year, when the rivers are full.

The western part of the state is drained by the two principal branches of the Ohio, the Alleghany and Monongahela rivers. The Alleghany rises within this state on the table-land near 78° W. long. and 41° 50′ N. lat.: and after a circuitous course of about 30 miles it enters New York, where it becomes navigable for small boats at the town of Olean. About 20 miles lower down it re-enters Pennsylvania, and runs about 150 miles more, principally by a southern course and with numerous windings between high hills, to its junction with the Monongahela at Pittsburg. Though rather a rapid river, running at the rate of about two miles an hour, it is navigable for boats during several months of the year. The other branch of the Ohio, the Monongahela, rises in Virginia, near 38° 30′, about 250 miles from the source of the Alleghany. Its upper course is between the ridges of the Appalachian mountains, and impeded by rapids. The last of these occurs some miles south of the southern boundary of Pennsylvania, where the river breaks through the Chestnut Ridge. From this place it is navigable for boats to its junction with the Alleghany at Pittsburg. Its course is in general nearly north, and it runs perhaps not less than 200 miles. The Ohio, which is formed by the junction of these two branches, runs westward about 40 miles through Pennsylvania, and is joined from the north by the Big Beaver river, which is navigable for boats as far as the boundary-line between Pennsylvania and Ohio. As to the Ohio, see Mississippi, vol. xv, p. 284.

Productions.—The principal agricultural products and forest-trees have been already noticed. The waggon horses of Pennsylvania are of extraordinary size and strength. Their average height is about 5 feet 4 inches, but the larger sometimes attain a greater height. Cattle are numerous, especially in the north-west region, and generally of a good breed. Sheep are kept in most parts, but the wool is not fine. The wild animals have much diminished. The elk has entirely disappeared, and the deer begins to be scarce. In the northern and less cultivated districts are still found the brown bear, the wolf, wild cat, fox, racoon, and opossum; also squirrels, rabbits, hares, and minxes. Among the birds, the wild turkey is the largest. Several kinds of fish are plentiful in the rivers, as salmon, trout, carp, shad, &c.

Pennsylvania is rich in minerals. The most important is coal, both anthracite and bituminous. The anthracite coal is found near the eastern extremity of the ridges of the Appalachian mountains, from 50 to 80 miles from the banks of the Delaware river, where it exists in three large fields or deposits. The most southern lies on the northern side of the Blue Mountains, where, according to a rough estimate, it occupies an extent of country 65 miles in length and 5 miles wide, or an area of 325 square miles. It is worked in several places, near Port Carbon on the Schuylkill, and near Mauch Chunk on the Lehigh. The quantity of coal extracted from this field in 1833 amounted to 429,[illegible] tons. The second field lies farther north on both sides of the Lackawannock, a branch of the eastern Susquehanna, and is said to occupy a similar extent of country. It is worked at some places, and in 1833 not less than 161,[illegible] tons of coal were taken from it. The third coal-field lies farther inland on both sides of the Susquehanna, above its confluence with the Juniata. It is not yet worked. It is supposed that these three coal-fields occupy an area of [illegible] square miles. The bituminous coal-fields of Pennsylvania lie on the western declivity of the Alleghany mountains, where the coal is found in beds varying in thickness from an inch to six feet and upwards. These beds extend over an immense tract southward into Maryland and Virginia, but it is not known if they pass the boundary of New York. It is stated that they occupy an area of 2[illegible],000 square miles, which is probably an exaggeration. The abundance of coal gives to Pennsylvania a great advantage as a manufacturing country. The western coal-fields are little worked, as the surrounding country abounds in forests; but in the manufactures of Pittsburg, and in those of salt, about 250,000 tons are annually consumed.

Salt-springs are common all over the region of the bituminous coal. Wherever the earth in this region has been penetrated to any considerable depth, salt water has been found, and salt-works on a large scale exist on the Conemaugh, an affluent of the Alleghany river, and at several other places. The quantity of salt obtained in them was, in 1834, estimated at one million of bushels. Iron-ore is abundant all over the state, except the south-eastern region, and is worked in several places, but not to a great extent. Copper and lead occur in some places. Marble of beautiful variety and excellent texture is found in the hills of the south-eastern region, and is much used in building. Slate and limestone abound in some places.

Canals and Railroads.—The first canals were made for the purpose of bringing the produce of the coal-mines to the market. The oldest is the Schuylkill Canal, which was commenced in 1816. It begins at the Fair Mount water-works, near Philadelphia, and extends along the Schuylkill river to Reading, and thence to Mount Carbon, where the mines are worked. Its length is 108 miles, of which 16 lie in the bed of the river, and the rest in canals. In 1833 not less than 261,654 tons of goods descended this canal, of which 252,971 were coal, and 33,219 lime and limestone. In the same year 54,735 tons of goods ascended it. The Lehigh Canal, which was only finished in 1836, extends from Easton on the Delaware, up the Lehigh river, to the coal-mines of Mauch Chunk, a distance of 46 miles. It is of larger dimensions than the other canals, admitting boats of 150 tons. In 1833, 123,000 tons of coals were brought down, but at present probably more than twice that quantity. The Lackawaxen Canal begins at the confluence of that river with the Delaware, and extends to Honesdale 26 miles; from Honesdale a railroad runs to Carbondale, a distance of 16 miles, to the coal-mines in the county of Luzerne. More than 100,000 tons of coal were brought down this canal in 1833.

The canals, designed in general for the transport of goods, began to be made only about fifteen years ago. The chief is the Delaware and Erie Canal, which connects the Delaware river with Lake Erie. This great line of communication begins at Philadelphia with a railroad, which traverses the south-eastern region, and terminates at Columbia on the Susquehanna. At this place a canal begins, which extends along the river upwards to the mouth of the Juniata. It thence follows the course of the last-mentioned river to Huntingdon, where it leaves the main body of the Juniata, and runs along one of its affluents, called the northern branch of the Juniata, to the foot of the Alleghany mountains, where it terminates at Hollidaysburg. The Alleghany mountains, which rise more than 1400 feet above their base at Hollidaysburg, are traversed by a railroad 36 miles long, which terminates on their western side at Johnstown. Here the second line of canals begins, which first runs along the banks of the river Conemaugh to its confluence with the Alleghany, and then along the last-mentioned river to Pittsburg, where it ends: the Ohio, between Pittsburg and the mouth of the Big Beaver river, a distance of 26 miles, constituting the link which connects the second line of canal-navigation with the third line. The Big Beaver affords an easy navigation for canal boats as far up as Newcastle, 24 miles, where the third line begins. This line runs along the Big Beaver to its very source, traverses the high country dividing that river from the Cuyahoga river near Ravenna, and joins the Erie and Ohio canal near Akron. The last-mentioned canal terminates at Cleaveland on Lake Erie. [OHIO.] The whole distance from Philadelphia to Cleaveland by this route is about 530 miles, of which 118 are by railroads, 52 miles by the Ohio and Big Beaver rivers, and the remainder by canals.

Several lateral lines are connected with this great line of internal communication. From the mouth of the Juniata river a canal runs up the Susquehanna to Northumberland, where the two great branches of that river unite. At this place another canal begins, running up the eastern Susquehanna to a point two miles below Wilkesbarre. These two canals taken together are 95 miles long. From Northumberland another canal proceeds along the western Susquehanna to the centre of Lycoming county; it is 70 miles long. A canal has been made to connect the Schuylkill canal with the great line, which is called the Union Canal. It begins near Reading on the Schuylkill, and runs along the bed of two small rivers, the Tulpehoken, an affluent of the Schuylkill, and the Swatara, a tributary of the Susquehanna, terminating on the last-mentioned river at Middletown; it is 82 miles long.

As the Delaware river above Trenton presents obstructions to navigation for several months of the year, a canal has been made along its course. It begins at Bristol on the Delaware, and terminates at the mouth of the Lehigh. This canal is 60 miles long. One of the upper branches of the Alleghany river, called the French Creek, has much water, but is not navigable for boats, on account of several rapids. A canal has accordingly been made along its course, which extends from its confluence with the Alleghany in Franklin, a distance of about 22 miles.

All the canals of this state are now 900 miles in length, of which about 600 miles are at the expense of the state; and the railroads which are connected with them are 118 miles. The expenses incurred by the state in the construction of canals exceed considerably the sum of 22 millions of dollars. The canals leading to the coal-mines, and the Union Canal, have been made at the expense of incorporated companies of private persons, and have cost more than six millions of dollars.

Inhabitants.—According to the census of 1820, the population of Pennsylvania consisted of 1,049,458 individuals, which, in 1830, had increased to 1,348,233, which was an increase of more than 28 per cent. In the last-mentioned year there were nearly 30 persons to a square mile. There were then 38,333 persons of colour among the inhabitants. The population is very unequally distributed. The south-eastern region, though it forms less than one-sixth of the area, contains nearly one half of the population, and the north-western region, which is little more than half as large as the mountain region, equals the latter in population. In the mountain region the population to a square mile hardly exceeds 12 individuals, while there are nearly a hundred to a square mile of the south-eastern region.

In no part of the United States is the number of German settlers and their descendants so large as in Pennsylvania. There are districts in which the German is the prevailing language. It is supposed that the Germans form one-fourth of the population. They have their own schools and institutions of education, in which the instruction is given in the German language. A great number of German newspapers are printed. The Germans are either Calvinists or Lutherans. The native tribes, which, in the middle of the last century were still in the undisturbed possession of the mountain and north-western regions, have entirely disappeared.

Manufactures.—Pennsylvania is one of the most manufacturing of the United States. Though the manufactures of cotton, woollen, and linen stuffs are less extensive than those of New York and Massachusetts, those of iron, paper, and glass are the most extensive in the Union. The iron manufactures occupy the first place. They are chiefly in the north-west region, at Pittsburg, Brownsville on the Monongahela, and some other places. One of the principal objects is the manufacture of steam-engines for the navigation of the Ohio and Mississippi, and for the railways. In 1830 not less than one hundred steam-engines were made at Pittsburg. Next to this are sugar-mills and machinery for a great variety of purposes; and then follows a long list of utensils, as stoves, chain-cables, mill and crosscut saws, spades and shovels, wood-screws, sickles, hammers, gimlets, braziers' rods, door locks, latches, knives, razors, and various kinds of carpenters' tools. The finer kinds of edge-tools, as well as rifles and muskets, are not made to so great an extent, though of late there has also been an increase in this branch of the iron manufacture. Glass appears to be the second manufacture as to amount. There are glass-houses at Pittsburg, Brownsville, and near Philadelphia, and great quantities of flint glass, domestic glass, window-glass, and bottles are made and sent to other states. The manufactures of paper are perhaps almost equal in value to those of glass. More than fifty years ago there were numerous paper-mills, and the number has now greatly increased. They are dispersed over the more inhabited districts. Leather-making is also a considerable branch of industry. The largest tan-yards are at Pittsburg, but they are numerous in the smaller towns in the north-west region. In several places hats are made, as at Philadelphia, Pittsburg, and at Reading on the Schuylkill, and at Bedford on the Juniata. There are also manufactures of sail-cloth, ropes, stockings, potash, tobacco, earthenware, china, candles, coaches, &c.

Commerce.—The produce of the agriculture and manufacturing industry of Pennsylvania is carried to the other states of the Union or to foreign countries by three different routes. The south-eastern region sends its products by the way of Philadelphia, which is the only seaport in the state. [PHILADELPHIA.] Though at present a complete line of communication by means of canals and railroads exists between the south-east and north-west regions, the greater quantity of the produce of the last-mentioned country is too heavy to be transported about 500 miles in such a manner. It was accordingly formerly sent to the western states by boats and smaller vessels which navigated the Ohio and Mississippi to Cincinnati, St. Louis, and New Orleans, from which places it reached the place of consumption. But since the canal uniting Pittsburg and Cleaveland (the port of Ohio on Lake Erie) has been finished, a considerable portion of the goods produced and made in the north-western region finds its way into the state of New York, and those of New England through Cleaveland and the Erie

Canal. This new route cannot fail to increase in a very considerable degree the manufacturing industry of that part of Pennsylvania.

Political Divisions and Towns.—Pennsylvania is divided into fifty-one counties. The seat of government is at Harrisburg, on the Susquehanna, not far from the place where the river issues from the mountains. It is well laid out. In 1830 it contained 4307 inhabitants, but it can only rise to importance when the northern district is well inhabited and cultivated. The largest town of the state is Philadelphia. [PHILADELPHIA.] South-west of it, on the banks of the Delaware, is Chester, with 1500 inhabitants, and a good anchorage. Easton, likewise on the Delaware, at the mouth of the Lehigh river and the commencement of the Lehigh canal, is a thriving place, with more than 3000 inhabitants. Reading, on the banks of the Schuylkill, near the place where the Union canal joins the Schuylkill canal, is a very thriving place, which in 1830 had 5831 inhabitants, and hat manufactures. Lebanon, on the Union canal, has above 2000 inhabitants. Lancaster, the largest place in the south-east region next to Philadelphia, had, in 1830, 7684 inhabitants, mostly employed in the manufactures of cotton and wool, iron, leather, hats, ropes, and tobacco. North of it is Ephrata, or Dunkertown, the principal settlement of the German Anabaptists, who have established several manufactures of linen, wool, paper, parchment, and leather. Carlisle, not far from the foot of the Blue Mountains, in the fertile valley of Cumberland, has 3000 inhabitants, and a college called Dickinson College. York has 3000 inhabitants, and some manufactures on a small scale, with an academy for Germans. Gettysburg, a small place, has a college for Lutheran clergymen: in its vicinity some silver-ore was found in 1826.

None of the towns in the mountain region have risen into importance. Sunbury and Northumberland, as well as Wilksbarre, are advantageously situated on the Susquehanna canal; and Lewistown and Huntingdon on the Delaware and Erie canal. Bedford, on the Juniata, which begins to be navigable at this place, has some commerce, and manufactures hats.

The most important place in the north-west region is Pittsburg, which stands on the peninsula formed by the confluence of the Alleghany and Monongahela rivers, where the navigation of the Ohio in larger boats begins, and on the site of the old French post Fort Duquesne. It is the principal point through which the traffic between the countries west of the Appalachian Mountains and those along the Atlantic is carried on by land. Besides the line of communication established by canals and railroads, an excellent turnpike-road leads through Maryland to Baltimore and Washington. The navigation on the Ohio, Big Beaver river, and the canal to Cleaveland in Ohio, increases the great advantages possessed by this place, among which the most important are the immense beds of coal which surround the town. The population has rapidly increased. In 1820 it was 7248; in 1830, 12,568, exclusive of the suburbs, and with them, 22,433; and probably it is at present nearly 50,000. In the beginning of 1835 there were sixteen foundries and engine-factories on a large scale, besides some of less magnitude; nine rolling-mills, cutting two tons of nails and rolling eight tons of iron per day; six cotton factories, having 20,000 spindles and 116 power-looms; six extensive white-lead factories; six steam saw-mills; four steam grist-mills; five large breweries; ten extensive glass-works; and upwards of 100 steam-engines in full operation; besides numerous other manufactures in iron, wood, and leather, on a small scale. Brownsville, on the Monongahela, which becomes navigable some miles higher up, is a small but thriving place, with some iron-manufactures. Erie, a small place with 1500 inhabitants, on the shores of Lake Erie, is a port of entry, but has little commerce, the surrounding country being very thinly inhabited.

Education and Religion.—The state has nine colleges, five of which are in the eastern part of the state, and four in the western. The University of Pennsylvania, in Philadelphia, has an academic faculty of five professors, and a medical faculty of nine professors; it is the largest and best medical school in America. Dickinson College, at Carlisle, has four instructors, and a library of 7000 volumes. La Fayette College, at Easton, has a president and three professors. Pennsylvania College, at Gettysburg, has a president and four professors. Bristol College has a president and five instructors. The Western University, in the northern suburbs of Pittsburg, has four instructors. Jefferson College, at Canonsburg, has a president and six professors, w[illegible] library of 3500 volumes. The Jefferson Medical Sc[illegible] which is in Philadelphia, is a branch of this institution, [illegible] has six professors. Washington College, at Wash[illegible] has seven instructors, and a library of 1500 volumes. A[illegible] hany College, at Meadville, has four instructors, and a l[illegible] of 8000 volumes. None of these institutions, the [illegible] departments excepted, have attained a high reputa[illegible] and indeed education generally is far less an object [illegible] pular favour in Pennsylvania than in the States north [illegible] In 1831 however provision was made by the legislat[illegible] a 'common school fund,' which was to accumulate un[illegible] amounted to 100,000 dollars a year. Bethlehem, a M[illegible] vian settlement on the Lehigh, is the seat of a very su[illegible] ful seminary for females. As to the munificent dona[illegible] Stephen Girard to the city of Philadelphia, see that ar[illegible]

The principal sects in the state are Presbyterians, M[illegible] dists, Baptists, German Reformed, and Episcopal an[illegible] Quakers are also numerous in the eastern part of the [illegible] and the Roman-Catholics in every part. A large [illegible] the population of Pennsylvania, especially in the middl[illegible] western districts, are Germans; they retain the use [illegible] language, and a considerable number of newspapers [illegible] German are printed and circulated in the state.

History and Constitution.—The first settlements on [illegible] shores of Chesapeake Bay were made by the Swedes in [illegible] Though engaged in a long war with the Poles, Gu[illegible] Adolphus sent a small colony to this part of America, [illegible] settled on Chesapeake Bay. But his attention was [illegible] diverted from it by the wars in Germany. When Char[illegible] was at war with Denmark, and the Dutch had de[illegible] against him, they took possession of the Swedish [illegible] in 1658, and kept it, but were obliged to cede it to the E[illegible] lish in 1664. Several dispersed settlements had [illegible] formed along both sides of Chesapeake Bay. The c[illegible] was granted by Charles II. in 1681 to William Penn, wh[illegible] sidered it just to buy from the original possessors, the In[illegible] what had been granted by the king of England. In 1[illegible] founded the town of Philadelphia, and framed a consti[illegible] which was confirmed by an assembly of the people at C[illegible] in December, 1682. The humane principles on which [illegible] constitution and laws of Penn were based, attracted n[illegible] rous colonists to this country from most parts of E[illegible] especially from Germany. They all settled however [illegible] south-east region, whilst the Indians remained in u[illegible] turbed possession of the north-west region. The Fr[illegible] advancing from Canada, got possession of this back c[illegible] and built Fort Duquesne in 1752. This fortress was [illegible] Pittsburg after it was taken by the British. In th[illegible] the colonists who inhabited the country near the m[illegible] suffered much from the incursions of the Indians, w[illegible] taken part with the French. In 1774 the delegates [illegible] colonies assembled in Philadelphia, declared against [illegible] right of the English parliament to tax the co[illegible] which may be considered as the declaration of [illegible] and in 1776 the representatives of the thirteen sta[illegible] clared their independence. The seat of the federal g[illegible] ment was at Philadelphia till 1800, when it was rem[illegible] Washington. The constitution of Penn was amende[illegible] ral times, and remodelled in 1777, after the declarati[illegible] independence. The last alteration was in 1838. Acc[illegible] to this constitution, the legislature consists of tw[illegible] a House of Representatives and a Senate. The nu[illegible] representatives is 100. They are elected for one y[illegible] all persons who are twenty-one years of age, who [illegible] sided two years within the state, and have paid taxe[illegible] number of senators is thirty-three. They are chose[illegible] four years, in districts, by the same persons who are e[illegible] to elect the representatives: one-fourth are annually re[illegible] The executive power is vested in the governor, wh[illegible] by the citizens for three years, and may, if re-elect[illegible] his office nine years out of twelve. Pennsylvan[illegible] two members to the Senate, and twenty-six members [illegible] House of Representatives at Washington.

PENNY. [COIN.]

PENNYROYAL. [MENTHA PULEGIUM.]

PENOBSCOT. [Maine.]

PENRITH. [Cumberland.]

PENRYN, a corporate town in the parish of Gluvias, in the east division of the hundred of Kerrier, in the county of Cornwall, 271 miles from the Post-office, London, by the Falmouth and Exeter mail road, which is by the south-western railway to Basingstoke, and thence, by road, through Andover, Salisbury, Exeter, Launceston, and Bodmin.

Penryn was made a market-town A.D. 1236, and was incorporated by James I. It was garrisoned by Charles I. in the great civil war, and surrendered to Fairfax, March, 1646. The town is about two miles from Falmouth, at the end of one of the inlets of Falmouth Harbour. It is built on a low hill projecting eastward into the inlet and dividing it into two navigable branches. At the point between these branches is the public quay, from which place the main street of the town gradually rises along the ridge of the hill to its western extremity, more than half a mile in length, having other streets and lanes branching off into the valleys on each side. The two navigable branches of the inlet from Falmouth Harbour allow a commodious quay for vessels, and there is a considerable trade carried on between Penryn and the populous mining district of Redruth. There is an episcopal chapel, and several dissenting places of worship. The area of the municipal borough comprises 230 statute acres. In 1831 it contained 398 inhabited houses, and in 1835, 722 (*Municipal Corporation Boundaries Report*); the population, in 1831, was 3521, a small part agricultural. The buildings of the town extend beyond the borough limits into the parishes of Gluvias and Budock. The trade consists in the exportation of granite (which is considerable and increasing), and in the importation of corn and flour for the supply of the surrounding district. There are colour-works, corn-mills, breweries and numerous shops. There is a weekly market, and there are five cattle-fairs in the year.

The borough returned two members to parliament from the time of James I. By the Reform and Boundary Acts Falmouth was, for parliamentary purposes, united with it. The number of voters in the year 1835-6 was, for the united borough, 882. The council, by the Municipal Reform Act, consists of 4 aldermen and 12 councillors, but the borough was not to have a commission of the peace except on petition and grant. An enlargement of its municipal boundary is proposed in the Commissioners' 'Report.' Penryn is a chapelry or perpetual curacy in the vicarage of Gluvias.

There were, in 1833, in the borough, one infant-school, with 50 girls and 80 boys; one national school, with 130 boys; nine other day-schools, with 217 children of both sexes; two boarding-schools, with 77 children; and three Sunday-schools, with 365 children of both sexes. In that part of Gluvias parish which is not included in the limits of the borough there were three day-schools; one, a national school, with 137 boys, and two others with 42 children; and one Sunday-school, with 150 children.

PENSA is an extensive government of Russia in Asia, which, after having formed a province of the Khanate, or great government of Kasan, was erected into a separate government in 1780. In 1796 it was united with the government of Saratoff, from which it was again separated in 1801 by the Emperor Alexander. It is bounded on the north by Nischnei Novogorod, on the east by Simbirsk, on the south by Saratoff, and on the south-west and west by Tamboff. It lies between 52° and 54° N. lat., and between 42° 30′ and 46° 30′ E. long. The surface is slightly undulating, and the general character of the country is a plain. It is watered by numerous rivers, but most of them are small and not navigable. The most important rivers are the Soura and the Moksha. The Soura, which rises in Saratoff, passes Pensa to the south of the chief town, traverses the eastern part of the government, and enters Simbirsk. The Moksha rises in the government itself, waters the north-west part of it, and after running northwards turns to the west, and enters the government of Tamboff. The government contains six small lakes. The climate is temperate and very agreeable in summer, but the winter is rather cold; the sky is clear and the air very healthy.

The soil is extremely fertile and produces, without manure, fine crops of wheat, rye, barley, and oats, which not only supply what is required for the home consumption, but a considerable overplus for exportation. Hemp and flax flourish, and the gardens produce all kinds of vegetables. Tobacco and hops are not grown, and potatoes only here and there. The inhabitants grow apples, pears, and cherries, but pay little attention to them. Wild berries of various kinds are extremely plentiful. The forests are of vast extent, but, as we have observed in other provinces of Russia, the most extravagant waste has been committed in them. Firs are rare in the forests, which consist chiefly of the oak, the beech, the birch, and the alder. There are still wild deer and a great quantity of game, but the fur-bearing animals have disappeared. The chief occupations of the inhabitants are grazing and agriculture, and the Mordwins in particular have great quantities of bees. The fisheries are of little importance. The mineral kingdom furnishes a little iron, vitriol, sulphur, and saltpetre. The population and extent of this government have been variously stated. Dr. Schnitzler (1835) gives it an extent of 16,100 square miles, and only 470,000 inhabitants, in which he has probably, by an oversight, taken the number of males, who alone are counted in most of the governments. But M. Keppen, member of the academy of sciences, who is employed under the minister of the domains of the empire, has just published a very remarkable memoir on the population of the Russian empire in 1838, which is not only the latest but probably the most correct that has yet appeared. He states the population of Pensa at 486,021 males and 502,779 females (total 988,800); and the territorial extent at 15,167 square miles, divided into ten circles. The great majority of the inhabitants are Russians of the Greek church, with whom some Cossacks are blended, but there are also Mordwins (about 15,000 males), mostly converted to Christianity; and Kasan Tartars (9000 males), who are still Mohammedans. The very few followers of Schamanism are among the Mordwins.

There are few manufactures, properly so called, on a large scale. A few years ago there were twelve of cloth, seven of soap, three of glass, six of beet-root sugar, besides thirty-four tan-yards, &c. But the country-people manufacture coarse linen and woollen cloth, and all kinds of articles for their own use. There is a manufactory of blankets and carpets at the village of Jelá. The distilling of brandy is carried on to a very great extent. The trade is chiefly carried on by land, especially with Nischnei Novogorod. Annual fairs are held at Pensa, Nischnei Lomoff, and Saransk. The exports are corn, flour, brandy, soap, wax, honey, potashes, wool, sail-cloth, carpets, blankets, wooden ware, &c.

With respect to public instruction, Pensa is under the university of Kasan, but the schools are few in number. The only printing office belongs to the crown. There are in the government 619 churches, of which 11 are cathedrals, five monks' convents, and one nunnery. The Tartar mosques are to the number of 70, of which 33 are of the first class.

Pensa, the capital of the government, is built on an eminence at the conflux of the Pensa and the Soura, in 53° 7′ N. lat. and 44° 55′ E. long., 465 miles from Moscow. It was founded in 1666, and is a flourishing town, with manufactories of leather and soap, in which, and in corn, there is a brisk trade. Pensa is a bishop's see, and has a gymnasium, a seminary, two convents, to each of which two churches are attached; seven other churches, and a cathedral. The houses are all of wood, and the population 11,000. The capitals of the other nine districts, though not very interesting, are pretty considerable; the principal are Nischnei-Lomoff (7000 inhabitants), where a great annual fair is held from the 1st to the 15th of July; the chief articles sold are leather, furs, wax, drugs, and colonial produce; and Saransk, at the conflux of the Saranga and the Issara. It has nearly 9000 inhabitants, nine churches, two cathedrals, and a convent of monks. It is a very thriving little town.

PENSACOLA. [Florida.]

PENSION, an annual sum granted by the state to an individual. The grounds upon which pensions are granted by the state differ according to the nature of the government. In a monarchy the services rendered to the sovereign by those who surround his person will recommend them as fitting objects of reward; where a mixed form of government prevails, attempts will be made to establish some standard of reward independent of personal bias or caprice. In this country the distribution of pensions is now almost entirely subject to the control of the legislature; but the following notice will show that persevering and long-continued efforts have been necessary to place it upon this footing.

Before the reign of Queen Anne, the kings of England alienated or encumbered their hereditary possessions at pleasure, and the courts of law sustained them in the exercise of this power. In 1690-91, Chief-Justice Treby, in answer to the objection that such power might lead to the destruction of the revenue, said, 'This might be some reason to induce the making of an act of parliament to restrain the king's power of alienation; but since here the parliament has thought fit to give the king such a power, we ought to acquiesce and submit to it.' (*State Trials*, vol. xiv., p. 30.) By the 1 Anne, c. 7, the right of burthening the revenue of the crown with improvident grants, to the injury of the successors of the throne, was materially abridged. This statute, after reciting that 'the necessary expenses of supporting the crown, or the greatest part of them, were formerly defrayed by a land revenue, which hath from time to time been impaired and diminished by the grants of former kings and queens of this realm,' enacts that no grant of manors, lands, &c. shall be made by the crown from and after the 25th of March, 1702, beyond the term of thirty-one years or for three lives, reserving a reasonable rent. As this clause applied only to the land revenue, it was enacted by another clause that no portion of other branches of revenue, as the excise, post-office, &c., should be alienable by the crown beyond the life of the reigning king. On the accession of George III., in consideration of the surrender of the larger branches of the hereditary revenue, a civil list was settled on his majesty, amounting originally to 800,000*l.*, and afterwards increased to 900,000*l.*, on which the pensions were charged. There were no limits, except the Civil List itself, within which the grant of pensions was confined; and at various times, when debts on this list had accumulated, parliament voted considerable sums (Sir Henry Parnell, in his work on 'Financial Reform,' says 'some millions') for their discharge. In February, 1780, during the administration of Lord North, Mr. Burke introduced his bill for the better security of the independence of parliament and the economical reformation of the civil and other establishments. In this bill it was recited that the pension lists were excessive, and that a custom prevailed of granting pensions on a private list during his majesty's pleasure, under colour that in some cases it may not be expedient to divulge the names of persons on the said lists, by means of which much secret and dangerous corruption may be hereafter practised. Mr. Burke proposed to reduce the English pension list to a maximum of 60,000*l.*, but the bill, as passed, fixed it at 95,000*l.* This act (22 Geo. III., c.) asserted the principle that distress or desert ought to be considered as regulating the future grants of such pensions, and that parliament had a full right to be informed in respect to this exercise of the prerogative, in order to ensure and enforce the responsibility of the ministers of the crown. Mr. Burke's speech on introducing his bill will be found in the third volume of his 'Works,' ed. 1815.

Up to this time the Civil List pensions of Ireland, the pensions charged on the hereditary revenues of Scotland, and the pensions charged on the 4½ per cent. duties, had not been regulated by parliament.

In Ireland the hereditary revenue of the crown was used as a means of extensive political corruption, the English act of 1 Anne, already cited, not being applicable to Ireland. In a speech of Mr. Hutchinson, secretary of state, made in the Irish House of Commons, in June, 1793, he stated that the gross annual hereditary revenue of Ireland amounted to 764,627*l.*, reduced by various charges to 275,102*l.* only; that the disposition of this revenue was in the hands of the king; that 'his letters and seals were the only authority for using it, and the only voucher allowed by the Commissioners of Accounts and by the House of Commons;' and that there was no Board of Treasury executing their functions under the authority of parliament. The Irish parliament, in 1757, had come to a unanimous resolution, 'That the granting of so much of the public revenue in pensions is an improvident disposition of the revenue, an injury to the crown, and detrimental to the people.' The Irish pensions then amounted to 40,000*l* : in two years after the above resolution was passed, an addition of 26,000*l.* was made to them; and in 1778 they were nearly double the amount at which they stood in 1757. In 1787 leave was refused to bring in a bill to limit the amount of pensions, and to disable persons holding pensions for a term of years, or during pleasure, from sitting and voting in parliament.' Mr. Forbes, who moved this bill, stated that 'it was a practice among certain members of the House to whom pensions had been granted, to carry them into the market and expose them for sale.' In 1790 Mr. Forbes again moved resolutions, stating 'that the Pension List amounted to 101,000*l.*, exclusive of military pensions; that the increase of pensions, civil and military, since February, 1784, had been 29,000*l.*; and that many of these pensions had been granted to members of parliament during the pleasure of the crown.' These resolutions were not adopted. In 17[illegible], when the whole policy of the Irish government was changed, among other beneficial measures introduced and recommended on the authority of the lord-lieutenant was a bill to limit the amount of pensions and to increase the responsibility of the Treasury, which was passed into a law. By this act (33 Geo. III., c. 34, Irish statutes) the pensions on the Civil List in Ireland were limited to 80,000*l.*, allowing a sum of 1200*l.* only to be granted until such reduction was effected. Grants held during the pleasure of the crown, and converted into grants for life to the same parties and the same amount, were exempted from the limitations of the act. This act carried into effect a surrender of the hereditary revenues for the life of the king, and the principle of appropriating money by parliamentary authority. These restraints on the crown were not however equal in efficiency to those contained in the English statute of Anne. At the time of the act of 33 Geo. III. being passed, the Irish pensions amounted to 124,000*l.*, and the amount was to be reduced to 80,000*l.* until 1814. By the 1 Geo. IV., c. 1, the Irish Pension List was further reduced to 50,000*l.*, no grant exceeding 1200*l.* to be made in any one year until the list was so reduced.

The statute of 1 Anne, having been passed prior to the Union, did not affect Scotland; and pensions were accordingly granted by the crown for life or for lives, in possession or in reversion, without restriction in amount or in the duration of the grant, other than the amount of the revenue and the claims and burdens already upon them. By the 50 Geo. III., c. 3, the principle of parliamentary interference was established in reference to the hereditary revenues of Scotland, the amount of the pensions was reduced to 25,000*l.*, and no more than 800*l.* was to be granted in any year until such reduction was effected. At this period the Civil List pensions of Scotland amounted to 39,379*l.* By the 1 Geo. IV., c. 1, the hereditary revenues of Scotland were placed to the account of the consolidated fund.

Certain duties, called the four and a half per cent. duties, were not withdrawn from the private control of the crown until 1830, when they were surrendered by William IV. for his life, the pensions then chargeable upon them continuing payable. On the accession of the late king (Wm. IV.) there was nothing therefore to prevent the Pension Lists of England, Ireland, and Scotland being consolidated; this was effected by 1 Wm. IV., c. 25, which also made provision for their reduction, on the expiration of existing interests, from an amount of 145,750*l.* net, to a future maximum sum of 75,000*l.* The Pension List for England was at that period 74,200*l.* net; Scotland, 23,650*l.*; Ireland, 47,9[illegible]

In 1830 the ministry of the Duke of Wellington was overthrown on the question of referring the Civil List (which comprises the Pension List) to a select committee, Sir Henry Parnell's motion to that effect being carried by 233 against [illegible]

In February, 1834, in order to define with greater precision the class of persons to whom the grant of pensions ought to be confined, Lord Althorp, chancellor of the Exchequer (now Earl Spencer), moved resolutions to the following effect, which were agreed to by the House of Commons:—'That it is the bounden duty of the responsible advisers of the crown to recommend to his Majesty for grant of pensions on the Civil List such persons only as have just claims on the royal beneficence, or who, by their personal services to the crown, by the performance of duties to the public, or by their useful discoveries in science and attainments in literature and the arts, have merited the gracious consideration of their sovereign and the gratitude of their country.'

On the accession of Queen Victoria, in 1837, the subject of pensions was again considered; and a select committee of the House of Commons, appointed to inquire into the Civil List, recommended,—'That in place of granting a sum of 75,000*l.* for Civil List pensions, her Majesty should be en-empowered to grant in every year new pensions on the Civil List to the amount of 1200*l.*, these pensions to be granted in strict conformity with the resolution of the House of Commons of February, 1834.' These views were adopted by the House, and embodied in the 1 Vic., c. 2, the words of the resolution being introduced into the Act. Since the accession of Queen Victoria, still greater force has been given to the spirit of the Act, in consequence of the recommendations of a select committee of the House of Commons, appointed in December, 1837, to inquire how far the pensions charged on the Civil List, as settled on the accession of William IV., ought to be continued, 'having due regard to the just claims of the parties and to economy in the public expenditure.' This committee, after a searching and protracted inquiry into the merits of each case on the Pension List, recommended the immediate suspension of several pensions, to be regranted on the responsibility of the government, should the circumstances of the parties render it necessary; others they considered should determine at an earlier period than specified in the original grant; and for several pensions, they considered it unadvisable to make any future provision. In their Report, dated July, 1838, the committee recommended that in the case of all future Civil List pensions, the reasons and motives of the grant should be set forth in the warrant of appointment; that in pensions granted for services to others than the individual by whom the services were rendered, care should be taken, if these pensions are granted for younger lives, that is, to the sons or daughters of the individual entitled to the pension, that no undue increase of charge should be made; and that such grants should be avoided, except under very peculiar circumstances: they recommended also that pensions for the relief of distress should be granted only on the condition of their ceasing when the circumstances of the parties no longer require their continuance; that all pensions should be held liable to deduction or suspension in the event of the parties being appointed to office in the public service; that under no circumstances should the mere combination of poverty with the hereditary rank of the peerage be considered as a justification of a grant of pension. The committee also recommended that, in order to avoid any possible doubt or misconception hereafter, enactments should be made with respect to the Irish and Scotch revenue analogous to those contained in the English statute of 1 Anne.

It appears from a table in the Report of the Select Committee on Pensions (No. 421, sess. 1838) that the charge of pensions has been reduced as follows:—

	England	Ireland	Scotland	4½ per Cent.	Total
	£	£	£	£	£
1784	86,000	80,000	12,300	16,700	195,000
1829	74,200	61,300	47,100	30,300	212,900
1837	74,200	36,900	33,200	21,100	165,400
1838	The lists consolidated.				146,900

Mr. Finlayson, of the National Debt Office, calculated, in 1838, the amount of saving which will be derived from the new system, assuming the ratio of decrease to continue as in the three previous years, and that the average ages of persons to whom new grants of pensions are made will be the same as heretofore:—

	Old Pensions.	New Pensions.	Total.
	£	£	£
1839	132,632	2,384	135,016
1844	97,340	5,677	103,017
1849	59,230	13,326	72,556
1854	30,702	18,245	48,947
1859	13,161	21,716	34,877

Mr. Finlayson was furnished by the committee with the ages of 986 persons in the receipt of pensions; and in 879 of these cases the date of the grant was ascertained. The mean age at which pensions were granted to males he found to be 53, and to females 39; and out of every 1000*l.* payable, 267*l.* was paid to males and 733*l.* to females. Mr. Finlayson complains that 'the females have understated their ages very considerably, and sometimes with a contempt of all probability, more than one lady having set down her age at 10, forgetting that she has been forty-five years in receipt of the pension, and thus from an infant to over the age of 40.'

The following is an account of the total amount of pensions granted in each year, ending the 20th day of June, from 1829 to 1839 inclusive:—

1829	-	£1853	1835	-	£1788
1830	-	5156	1836	-	1310
1831	-	2401	1837	-	2300
1832	-	7416	1838	-	640
1833	-	900	1839	-	330
1834	-	2479			

Besides the pensions on the Civil List, the regulation of which at different periods has been referred to above, there are vast sums annually appropriated by parliament to the payment of pensions of another description. Thus in 1836-7 the sum of 1,240,000*l.* was voted on account of the pensioners of Chelsea Hospital, 79,629 in number; 245,000*l.* to the out-pensioners of Greenwich; 145,000*l.* to 4083 widows of officers of land-forces; and to officers in each of the civil departments of the government large sums are annually paid in pensions and superannuation allowances. The half-pay to retired officers of the navy and army may also be considered in the light of a pension. In 1832 the charge on the public for pensions, superannuations, and half-pay amounted to 6,142,163*l.* (*Financial Reform*, p. 262, 4th edit.) 'The operation of the superannuation, the grant of retired allowances, the naval and military pensions granted for good services, the pensions granted by the 57 George III., c. 65, for persons who have occupied high political offices, and the pensions for diplomatic and consular services, have to a great extent superseded one of the original purposes of the Pension List. These acts have also substituted a strictly defined and regulated system of reward, for a system which depended on the arbitrary selection of the crown or the recommendation of the existing government, exposed to the bias of party or personal considerations.' (*Report on Pensions*, No. 913, sess. 1838.) Sir Henry Parnell, in chapter xii. of his 'Financial Reform,' shows that there are many abuses to be remedied in reference especially to superannuations. 'Nothing (he says) can be more extravagant and inconsistent with a proper guardianship of the public purse than the system of salaries and superannuations now in operation. The salaries are so much higher than they ought to be, that every officer and clerk has sufficient means of making a provision for infirmity and old age. But notwithstanding this fact, as to the sufficiency of salary, in the true spirit of profusion a great superannuation allowance has been added.' In 1830 there were nearly one thousand officers in the public service, with salaries of 1000*l.* a year and upwards, enjoying amongst them 2,026,374*l.*; and of these there were 216 persons whose salaries averaged 1422*l.*; and yet from the passing of the Superannuation Act in 1810 till 1830, the charge for civil superannuation was increased from 94,340*l.* to 480,081*l.* It was stated in the Third Report of the Finance Committee (sess. 1828), that in not a few cases persons obtained superannuations, as unfit for the public service, who enjoyed health and strength long afterwards, and discharged the active duties of life in private business. In 1831 the treasury established some very important restrictions relative to superannuation allowances, which are given in a Parliamentary Paper (No. 190, 2nd session, 1831).

For an account of pensions under the French monarchy the reader may refer to the *Encyclopédie Méthodique* (section 'Finances').

PENSIONARY, GRAND, was the name generally given to the first magistrate of the state or republic of Holland, which was a member of the confederation of the Seven United Provinces of the Netherlands. The Pensionary was the president of the council of the states or legislature of Holland, and he was at the same the first minister of the republic, transacted business with foreign powers, and like the Avoyer of Bern and other Swiss cantons. He was elected for five years, but was generally confirmed indefinitely, and often for life. He was also in virtue of his office the perpetual deputy of the state of Holland to the assembly of the states-general of the United Provinces, of which he was a most influential member, in consequence of the superior importance of the province of Holland. His name was derived from the pension which was attached to his office. He was also styled advocate-general to the states of Holland. The individual chosen for this high office was a person well versed in the science of the law, and he is styled by Grotius 'Adsessor Jurisperitus.' The various towns of Holland and Zealand had also each their pensionary, or chief municipal magistrate. [Barneveldt, Johan van Olden.]

PENTACHORD, an ancient Greek musical instrument, which had, as the word implies, five strings. The term also signified a scale of five sounds.

PENTA'CRINUS. [ENCRINITES.]

PENTADESMIS BUTYRA'CEA is a tree found in Sierra Leone, from which a fatty substance is obtained, which has given rise to its name of the Butter and Tallow Tree. It has an ovate fleshy fruit, about as large as citron, and its stamens are collected into five parcels, whence its botanical name. Little more is known of it than that it belongs to the natural order Guttiferæ or Clusiaceæ.

PENTALA'SMIS. [CIRRIPEDA, vol. viii., p. 207.]

PENTA'LEPAS. [PENTALASMIS.]

PENTATEUCH (Πεντάτευχος, from πέντε, 'five,' and τεῦχος, 'a volume') is the Greek name of the first five books of the Old Testament, which are called in Hebrew תּוֹרָה, *the law*. The Hebrew copies of the Pentateuch form one volume; the division of it into five books is first mentioned by Josephus, and seems to have been made either by the Septuagint translators, or before their time, and after the return of the Jews from Babylon.

The first, second, fourth, and fifth books of the Pentateuch have been treated of under GENESIS, EXODUS, NUMBERS, and DEUTERONOMY.

The third book is called Leviticus (Λευιτικόν), from its treating chiefly of matters pertaining to the priests, the sons of Levi. In Hebrew it is called, from its initial word, וַיִּקְרָא (*and he called*), or by the Rabbins תּוֹרַת הַכֹּהֲנִים (*the law of the priests*), and תּוֹרַת הַקָּרְבָּנוֹת (*the law of the sacrifices*). From the last verse of it (chap. xxvii. 34) we learn that it was written by Moses while the Israelites were encamped before Mount Sinai (compare *Numb.*, xxxvi. 13). The space over which it extends is the first month of the second year after the Exodus, B.C. 1490 (compare *Exod.*, xl. 17, with *Numb.*, i. 1). The twenty-seven chapters of which it consists may be divided into four parts, as follows:—1. The laws concerning sacrifices, including the burnt offerings (chap. i.), the meat-offerings (chap. ii.), the peace offering (chap. iii.), the offering for sins of ignorance (chaps. iv., v.), and the trespass offering for sins done knowingly (chaps. vi., vii.). 2. The institution of the priesthood, including an account of the consecration of Aaron and his sons, and of the punishment of Nadab and Abihu (chaps. viii.-x.). 3. The laws concerning clean and unclean animals, purifications, and expiatory sacrifices, including also sundry other enactments (chaps. xi.-xxii.). 4. The laws concerning sacred festivals, vows, things devoted, and tithes (chaps. xxiii.-xxvii.). Though the ordinances of this book were manifestly intended solely for the Jews, as is evident from their own nature, yet it contains matter of the highest import to Christians, inasmuch as the New Testament teaches that the rites of the Jewish sacred law were all or nearly all typical of the truths of Christianity; this is especially shown by St. Paul in his *Epistle to the Hebrews*, an epistle which would be almost unintelligible without the light thrown upon it by the book of *Leviticus*.

With regard to the Pentateuch in general, it has never been doubted, till at a recent period, that Moses was its author. The following are the chief arguments for its genuineness:—1. It is repeatedly asserted in the book itself that Moses was the author, and that he wrote it at the command of God. This assertion is made with regard to the whole book (*Deut.*, i. 5; xxxi. 9-13, 22, 24-26), and to separate parts of it (*Exod.*, xvii. 14; xxiv. 4, 7; xxxiv. 27; *Numb.*, xxxiii. 1, 2). And in the recapitulation of the law which Moses makes in the book of *Deuteronomy*, he frequently speaks of 'the law,' 'this law,' 'the book of the (or this) law,' 'the book of religion;' by which expressions we cannot fairly understand anything except either the whole Pentateuch, or that part of it which was already composed (*Deut.*, i. 5; iv. 44-45; xvii. 18, 19; xxviii. 58-61; xxix. 19, 20, 27, 29; xxx. 10). 2. In all ages of the Jewish history, from the time of Joshua downwards, the Pentateuch was received as the divinely inspired composition of Moses. Thus we read repeatedly in the Old Testament of 'the law,' 'the law of Moses,' 'the law of Jehovah,' 'the law which God gave by Moses,' 'the book of the law.' (*Josh.*, i. 7, 8; xxiii. 6; xxiv. 26; 1 *Kings*, ii. 3; *Psalms*, i. 1; and many other passages, which are collected in Rosenmüller's *Scholia*, and Jahn's *Introduction*.) Besides these direct testimonies, the existence and authority of the Pentateuch among the Israelites are proved by the fact that the institutions which it contains were always observed as the laws of their and that the sentiments of the Psalmists, the maxims of *Book of Proverbs*, and the reproofs and exhortations prophets, are all exactly in agreement with the sp those institutions. 3. The internal evidence is stro favour of Moses being the author. The language of book of *Deuteronomy* is that of an aged man addres people whom he had governed for forty years, appe their past experience, and speaking with all the earne of a man on the verge of death. If these characteris of any weight to show that the speaker and the wri this book were the same, then we are supplied with an a ment for the genuineness of the *whole* Pentateuch, f book of *Deuteronomy* supposes the previous compo *Exodus*, *Leviticus*, and *Numbers*, as these do that of Ge The information contained in the Pentateuch on jects of history and geography (especially with refere Egypt and Arabia), on natural history, diseases, the and military science, agrees with all the notions we form of the state of things at that remote period, and with we should expect from a man who, like Moses, had liberally educated at the Egyptian court, and had be gaged for forty years in leading a whole nation thro wilderness. The language of the Pentateuch is the antient known form of Hebrew; the assertion that its ference from the later Hebrew is far less than the of so great a time would necessarily cause in any lan is untrue. The style of the songs which are conta it possesses that plain sublimity which generally ch terises the first stage of a nation's poetry. The style narrative is better than that of any other Hebrew as we might expect from a highly educated man Moses; and it is not more varied than can be acc for by the different subjects treated of, and the inter at which the different parts were written. The arr ment of the matter is not that which would be a by a person digesting into one book previously ex tales and laws, but it is such as we might expect fr exposed to frequent interruptions in his work, and w corded each event as it occurred, which answers to the sition of Moses. The selection of the materials ap to have been made on the principle of recording things which were connected with the legislation w was the chief work of Moses, while of the laws thems some are repeated more than once, and others altered course of the work; all indicating that the legislator historian were the same person.

It is true that there are passages in the Pentateuch w could not have been written by Moses. But there is ficulty in explaining these passages as interpolati serted by a copyist with a view to make the meaning clearer. The following passages have bee in this class; but some of them may be explained wise:—*Deut.*, i. 1-4; iv. 44-49; *Exod.*, vi. 13-2 xi. 1-3; *Deut.*, ii. 10-12, 20-23; iii. 9, 11, 13-14; *Numb.*, xxxii. 41; *Deut.*, iii. 14; *Numb.*, xii. 3. T may be added the 34th chapter of *Deuteronomy*, wh it contains an account of the death and burial of M was not written by himself. In some parts however narratives, Moses appears to have made use of pre existing documents, especially at the beginning of of Genesis. [GENESIS.]

An account of the institutions recorded in the teuch has been given under MOSES.

(Rosenmüller, *Scholia in Vet. Test.*, vol. i. P *Pent.*, and others quoted by him; Jahn, *Introd Sac. Vet. Foed.*; Graves's *Lectures on the Pentat* Marsh's *Authenticity of the Five Books of M cated*; Horne's *Introduction*, vol. i, pp. 46-61.)

PENTATEUCH, THE SAMARITAN. The P teuch was the only part of the Old Testament w Samaritans received, and as, from feelings of mosity, they held no intercourse with the Jews, of the Pentateuch were preserved indepe Hebrew copies. The Samaritan Pentateuch is by several antient writers, but it was unknown in times till copies were obtained from the east by Arc Usher and Pietro della Valle. It was print copy procured by the latter in the Paris Poly nus, from which it was reprinted in Walton's P was also edited by Dr. Blayney in Hebrew cha Oxford, 1790. The original is in the Samarita Hebrew character.

The Samaritan Pentateuch is quite entitled to rank with the Hebrew as an independent source for settling the sacred text. In some places it gives readings manifestly superior to those of the Hebrew. In many passages in which it differs from the latter, it agrees with the Septuagint. Its chronology differs from that of the Hebrew Pentateuch. (Hales', *Analysis of Chronology*, vol. i., p. 272.) In *Deut.*, xxvii. 4, the Samaritan differs from the Hebrew by having Ebal for Gerizim, and vice versa. This has been regarded as an intentional corruption made for the purpose of flattering national prejudices. But Dr. Kennicott has shown good reasons for preferring the Samaritan to the Hebrew in this case. (*Diss.* ii., p. [illegible].)

PENTECOST, one of the three great Jewish feasts, so called because the day on which it began was the fiftieth (ἡ πεντηκοστή) from the second day of the Passover. It was also called the Feast of Weeks, from its falling at the end of a series of seven weeks, reckoning from the Passover, and also the Feast of the Harvest. It was a feast of thanksgiving for the harvest, at the end of which it fell, and among the sacrifices appointed for it were some of the first fruits of the harvest. This festival lasted eight days. The laws relating to it are contained in *Exod.*, xxiii. 16; xxxiv. 22; *Levit.*, xxiii. 15-21; *Numb.*, xxviii. 26-31; *Deut.*, xvi. 9-12.

PENTLAND FRITH. [CAITHNESS; ORKNEY ISLANDS.]

PENTOGRAPH. [PANTOGRAPH.]

PENTREMITES. [ENCRINITES.]

PENUMBRA (incomplete shadow), that portion of space which, in the eclipse of a heavenly body, is partly, but not entirely, deprived of its light. In a solar eclipse, as long as any part of the sun is visible, the parties observing are in the penumbra, and not in the umbra, or complete shadow.

PENZANCE, a corporate town in the parish of Madron, in the hundred of Penwith, in the county of Cornwall, 282 miles from the Post-office, London, by the south-western railway to Basingstoke, and from thence, by road, through Andover, Salisbury, Dorchester, Exeter, and Launceston. It is the most westerly town in England.

Penzance received a charter for a market and a fair, A.D. 1332, and was incorporated by charter of James I., A.D. 1614. It was burnt by the Spaniards, who landed at Mousehole, a short distance south of the town, A.D. 1595, and was plundered A.D. 1646, by the parliamentary troops under Fairfax, on account of the predilection shown by the townsmen for the royalist cause.

The town is situated on the north-western shore of Mount's Bay, and consists of several streets converging to the market-place, and of some smaller streets or lanes connecting them. The town has much increased of late years, and many of the houses are of modern erection, neat, and commodious. The number of inhabited houses in 1831 was 1264, of uninhabited 90, and 46 building. At the time of the Report of the Commissioners of Municipal Corporation Boundaries, more than 1500 houses were assessed to the poor-rate. The shops are numerous and good; the best are in the market-place. There is an episcopal chapel, with a small endowment; several dissenting places of worship, and a Jews' synagogue. The population has doubled during the present century; in 1831 it was 6563, and may be now probably estimated at from 7000 to 7500. The trade consists in the export of tin, copper, earthenware, clay, potatoes, barley, pilchards and other fish; and in the import of timber, coals, hemp, tallow, &c. A large proportion of the tin produced in Cornwall is shipped at Penzance. The pilchards are brought in by the fishermen of Mousehole and other places on the shore of Mount's Bay. There are a quay and pier near the southern end of the town, the dues upon which bring in a yearly revenue of 1000*l.* to the corporation. There are two weekly markets, one of them a considerable corn market, and three yearly fairs. Some woollen yarn and coarse woollen cloth are manufactured.

The climate of Penzance is very mild, and the place is consequently visited on that account by invalids suffering from pulmonary complaints.

The council, under the Municipal Reform Act, consists of six aldermen and 18 councillors. The borough boundary forms a semicircle round the town, having the market-place for its centre, and a radius of half a mile. The Boundary Commissioners recommend an extension of the limits. The borough is divided into two wards.

The borough has a commission of the peace. A Court of Record for the hundred of Penwith is held here every fortnight for personal actions not exceeding 50*l.* Quarter-sessions are held, and petty sessions every week. There is a small gaol, having two wards, one for men and one for women, each comprehending a yard and several cells, with a small treadwheel in a separate yard; but there is neither chapel, infirmary, nor bath.

The annual value of the chapelry of Penzance is 180*l.*; it was, before the Municipal Reform Act, in the gift of the corporation.

There were in the chapelry, in 1833, an infant-school, with 25 boys and 17 girls; an endowed grammar-school, with 12 boys; a school of industry, with 74 girls; two charity-schools, with 124 boys and 97 girls; a Jews' school, with 10 children; and thirty-eight other day-schools, with 1014 children of both sexes; and five Sunday-schools, with 802 children.

The church, which was rebuilt a few years ago, and the new town hall, both constructed of hewn granite, are great ornaments to the place. The latter building is surmounted by a handsome cupola, and its eastern front, consisting of a pediment supported by four noble columns, is a striking object. The taste of the inhabitants for scientific and literary pursuits is shown by their possessing a good public library, a Society of Natural History, and an Horticultural Society. This place is also the seat of the Royal Geological Society of Cornwall, whose museum contains one of the best collections of minerals in England.

PEONY. [PAEONIA.]

PEPAGO'MENUS, or more properly DEMETRIUS PEPAGOMENUS (Δημήτριος ὁ Πεπαγωμένος), one of the latest of the Greek physicians, is the author of a short treatise on the Gout, which is still extant. Nothing is known of the events of his life, but as his work was composed at the command of the emperor Michael Palaeologus, it must have been written between the years A.D. 1259 and 1282. 'This discourse,' says Freind (*Hist. of Physic*, vol. i.), 'though containing little extraordinary, and being collected out of other writers, chiefly Alexander, of whose work the eleventh book treats of this disease at great length, yet is far from deserving the character which M. Musurus, his translator, bestows upon the author (by name unknown to him), of *ineptus et elinguis*, &c., as if he could not express what he meant.' It consists of forty-five short chapters, besides the preface and conclusion, and, in the opinion of Sprengel (*Hist. de la Méd.*), does not deserve to be classed among the numerous worthless productions of the modern Greeks. He says that the author certainly does not depart from the system of Galen, but that his theory of the disease is more reasonable, and more in accordance with the observations of the moderns than that of most of his successors. He sets out with a true and precise axiom, viz. that the gout is a disease affecting the whole organized frame, and produced by weakness of the digestive organs and excesses in the matter of diet, &c. (cap. 7). The morbid principle, which is the result, is directed by nature towards the weakened articulations (cap. 8). Hence it follows that sobriety and temperance are the only means of preventing the disease (cap. 10). With respect to the cure he seems chiefly to have trusted in emetics and cathartics, and gives several prescriptions, some of which are borrowed, and others are apparently original. He particularly recommends a drastic purgative called *hermodactylus*, which is also highly praised by Alexander Trallianus (lib. xi.), and which Mr. Adams (in Barker's ed. of Lemprière, 1838) considers to be a species of *Colchicum Autumnale*, a medicine still considered by some practitioners to be almost a specific in this disease.

The treatise, περὶ ποδάγρας, 'De Podagrâ,' was first published in Latin, by Marcus Musurus, Romae, 1517, 8vo., with the title 'De Podagrâ Libellus nuper Autore e Graeco in Latinum conversus,' &c. This translation is inserted in the 'Medicae Artis Principes,' by H. Stephanus, Paris, 1567, fol. The Greek text was first published at Paris, ap. G. Morelium, 1558, 8vo., with a Latin translation (probably) by Turnebus. The last and best edition is by J. S. Bernard, Lugd. Bat., 1743, 8vo., Gr. and Lat., which is sometimes found with a new title-page, Arnheim, 1753. There is a French translation by Fred. Jault, Paris, 1573, 8vo. The Greek and Latin text is also to be found in the tenth volume of Chartier's edition of Hippocrates and Galen.

There is extant a treatise entitled [illegible], 'Dignotio Morborum in Hominibus, eorum que Curatio,' which is commonly printed among Galen's works, but which is however manifestly spurious, as the author professes himself to be a Christian. Fabricius, in his list of Galen's works, conjectures that Demetrius Pepagomenus may have been the author, but, in the opinion of Freind and Haller, there seems to be no good reason for such a supposition. In the collection of writers 'De Re Accipitrariâ et Venaticâ,' published by Nic. Rigaltius, Paris, 1612, 4to., are two treatises, which are perhaps the works of this same Demetrius. One is entitled *'Ιερακοσόφιον, ἢ περὶ τῆς τῶν ἱεράκων ἀνατροφῆς τε καὶ ἐπιμελείας*, 'Hieracosophium, sive De Accipitrum Educatione et Curatione,' containing an account of the different species of hawks, the mode of catching and training them, the diseases to which they are subject, and the remedies proper for each. The other is called *Κυνοσόφιον, ἢ περὶ τῆς τῶν κυνῶν ἐπιμελείας*, 'Cynosophium, sive De Canum Curatione,' and is sometimes attributed to Phæmon. It has been several times reprinted, but is not of much worth. He attributes madness in dogs to a worm underneath the tongue.

PEPIN D'HERISTAL (so called from a place in the kingdom of Austrasia, or Metz, called Heristal), or Pepin le Gros, was the son of Ansegisus, and grandson of Arnoul, who was duke of Austrasia in the reign of Dagobert I., afterwards bishop of Metz, and who was finally numbered among the saints. The mother of Pepin, named Begga, was the daughter of another Pepin, called Pepin the Old, or Pepin of Lander, who was Maire of the Palace under Dagobert I. and under his son Siegbert, king of Austrasia, was much respected for his personal character, and who died A.D. 640. Pepin d'Heristal became duke of Austrasia under Dagobert II., after whose death, A.D. 679, he governed the country as sovereign under nominal allegiance to Thierri III., king of Burgundy and Neustria. Thierri however became dissatisfied with Pepin, who revolted and defeated him, A.D. 690, and obliged him to recognise him as Maire du Palais, or in other words, the governor of the whole Frankish monarchy. Here begins the series of the 'Rois fainéans,' or 'do-nothing kings,' who succeeded one another as mere crowned pageants, whilst the Maire du Palais had all the real authority. Pepin ruled as such under Thierri, Clovis III., Childebert III., and Dagobert III., and thus made his authority respected, not only by the natives, but also by foreigners. He died in 714, having appointed his grandson Theodebaud to succeed him as Maire du Palais. But Charles Martel, a natural son of Pepin, was proclaimed duke of Austrasia by the acclamations of the people, A.D. 715, and in 719 he obliged Chilperic II. to acknowledge him as Maire du Palais as his father Pepin had been. [Charles Martel.]

PEPIN, king of France, called 'le Bref,' or 'the Short,' son of Charles Martel, was Maire du Palais after his father's death, under the nominal king Childeric III., for the kingdom of Neustria and Burgundy, whilst his brother Carloman governed that of Austrasia in a similar capacity. The two brothers defeated the Saxons, Bavarians, and Slavonians; and Pepin, in 744, defeated the duke of Aquitania, who had revolted. Soon after, Carloman, in a fit of devotion, gave up the government of Austrasia, and retired to a monastery at Rome, where he ended his days. All the authority was now concentrated in Pepin. What followed has been briefly and obscurely told by the chroniclers: 'King Childeric was dethroned, A.D. 750, his head was shaved (long hair was an essential appendage of royalty with the Merovingian kings), and he was confined in the monastery of Sithin, or St. Bertin, at St. Omer, and his son Thierri was sent to the convent of Fontenelle in Normandy, where he was brought up in obscurity.' (Henault, *Histoire de France*.) Eginhardt, the historian of Charlemagne, says, that 'Burckard, bishop of Wurtzburg, and the priest Fulrad, a chaplain, were sent to Pope Zacharias at Rome, to consult him concerning the state of France, in which the kings had merely the name of kings, without any royal power, and that the pope replied that it was better that he who exercised the royal authority should bear also the royal title; in consequence of which sanction, Pepin was constituted king.' And the continuator of the chronicler, Fredegarius, writing under the direction of Count Childebrand, Pepin's uncle, says, that 'by the consent of the Frankish nation, supported by the sanction of the Apostolic see, the illustrious Pepin being consecrated by the bishops and recognised by the princes, was raised to the kingdom, together with his Queen Bertrada, according to the antient usages.' We have no circumstantial account of this important event, except that
Pepin was anointed at Soissons, in March, A.D. 752, by
Boniface, bishop of Mainz, called the Apostle of Germa
before the assembly of the nation. It seems that t
ceremony of anointing the new king was introduced o
this occasion, having been unknown under the first or Merovingian dynasty. (Sismondi, *Histoire des Françai*.)

Sismondi thinks, with some degree of plausibility, th
this accession of a new family to the throne of the Fran
was not a mere change of dynasty, nor the usurpation of o
family over another, but that it was really a national re-
lution effected by the German population of Austrasia und
their leaders Pepin d'Heristal, Charles Martel, and h
son Pepin, who conquered Neustria and the other provin
of antient Gaul, and placed their own dynasty on t
Frankish throne. During the two centuries and a h
which had elapsed since the first conquest of Gaul by t
Franks under Clovis, the conquerors had become mixed
with the Gallo-Roman population, had adopted their la-
guage, manners, and effeminacy, and the original famil
the Franks had almost entirely disappeared in Neus
Aquitania, and Provence. But Austrasia, which exten
far on the right bank of the Rhine, had remained Germ
The family of Pepin led the Austrasian bands into the
of Gaul, which thus received a fresh infusion of Ge
manners, language, and military spirit. Pepin le Bre
order to conciliate the conquered Neustrians, raised C
deric III., of the old dynasty, to the throne, but this pag
was in reality the king of the conquered, while Pepin r
tained all the authority in his hands. The Neustr
looked upon the Austrasian bands as strangers and enem
When Pepin found that he could dispense with the pup
king, he put him aside with the sanction of Rome.

Pepin was grateful to the see of Rome, and when
Stephen III., Zacharias's successor, applied to him for as
ance against the Longobards, he marched with an army
Italy, defeated Astolphus, and made him promise to gi
the Exarchate and Pentapolis to the Roman pontiff. [Pa
State.]

Pepin waged successful wars against the Saxons, the B
varians, and other German nations; he defeated the
of Aquitania, and reunited his duchy to the domains of
crown; he favoured the clergy, and fixed the annual ger
assemblies of the Frankish nation for the month of M
He died of the dropsy, at St. Denis, in September, 7
54 years of age, in the 17th year of his reign. His
Charlemagne succeeded him as king of the Franks.

PEPIN, son of Louis le Débonnaire, and grandson
Charlemagne, was made by his father king of Aqui
A.D. 817, revolted repeatedly against his father, and d
838 or 839. The emperor disinherited Pepin's childre
their father's kingdom, and gave it to his own son Ch
the Bald.

PEPIN, Lake. [Mississippi, River.]

PEPO, a Latin term used by botanists to express
kind of fruit of which the gourd is the type. It is an u
seed-vessel, filled with pulp enclosed within a hard per
and furnished with parietal placentæ. It is a berry w
hard shell.

PEPPER. [Piper; Pimento.]

PEPPERMINT. [Mentha Piperita.]

PEPUSCH, JOHN CHRISTOPHER, an emi
musical theorist and composer, was born in 1667, at B
in which city his father was minister of a Protestant
gregation. At the early age of fourteen his talents attr
the notice of the Prussian court, in which he held som
pointment till he attained his thirtieth year, when,
eye-witness of a murderous act of tyranny perpetrated
Frederick I., he resolved to quit his country. He
visited Holland, where he remained upwards of a year;
proceeded to London, and about 1700 was engaged to
the harpsichord at Drury-lane theatre, and, it is supp
assisted in preparing for the stage *Thomyris*, as w
other operas. At the same time he commenced his inq
concerning the music of the antients, for which pursu
knowledge of the learned languages and studious h
highly qualified him. In these investigations he rec
no inconsiderable aid from his friend De Moivre,
mathematician. Though he had persuaded himself
the music of the Greeks was far superior to anything
the moderns were capable of producing, yet he did not h
tate to compose much, and was successful; though
one of his many works is known to the present age—

cantata, 'See from the silent grove Alexis flies,' which has always been, and probably always will be, admired by every person of true taste.

In the year 1710 this active and indefatigable musician was one of the founders of the *Academy of Antient Music*, which was formed on so judicious a plan that it subsisted upwards of eighty years. In 1712 he, together with Handel, was engaged by the Duke of Chandos (*Pope's Timon*) to compose for the chapel at Cannons. The next year he was admitted by the university of Oxford to the degree of doctor in music. In 1724 he was persuaded by Dr. Berkeley to join in the visionary scheme for establishing a college at the Bermudas, and actually embarked for the purpose; but the ship being wrecked, the project was speedily abandoned. He now entered into the matrimonial state with the celebrated singer Signora Margarita de l'Epine, who brought him a fortune, acquired by her profession, of ten thousand pounds. This addition—great in those days—did not induce him to relax in his pursuits: he selected and adapted, with admirable skill, the music for *The Beggar's Opera*, for which he composed the overture. In 1731 appeared his *Treatise on Harmony*, which long continued a standard work, and is still read by students who are wise enough to make themselves acquainted with the best writers on the art. In the year 1737 he was chosen organist of the Charter House, an appointment he solicited more for the sake of the apartments and the learned and agreeable society it afforded than with any pecuniary view. Three years after this he lost his wife; his only son having died some time before. He now found relief in his studies, to which, and in giving instructions to a few favourite pupils, he devoted himself wholly. In 1746 was read before the Royal Society his account of the *Antient Genera*, which appears in volume 44, No. 481, of the 'Philosophical Transactions;' previous to which however he had been elected a fellow of that learned body. Dr. Pepusch died in 1752, and was buried in the chapel of the Charter House.

PEPYS, SAMUEL, secretary to the Admiralty in the reigns of King Charles II. and King James II., was born February 23, 1632, of a family which had some pretensions to gentility, though he himself confesses it had never been 'very considerable.' His father, John Pepys, was a citizen of London, where he followed the trade of a tailor.

We learn from his diary that Pepys passed his boyish days in or near London, and was educated at St. Paul's school, where he continued till 1650, early in which year his name occurs as a sizar on the boards of Trinity College, Cambridge. Previously however to his going to reside in that university, March 5, 1650-1, he had removed to Magdalen College. How long he continued at Cambridge, or what were his academical pursuits, we are not informed. In 1655 he married Elizabeth St. Michel, a girl of fifteen. The consequences which might naturally have been expected to attend such an imprudent step were averted by the kindness of a relation, Sir Edward Montagu (afterwards earl of Sandwich), who gave the young couple an asylum in his family. In 1658 he accompanied Sir Edward Montagu in his expedition to the Sound, and on his return became a clerk in the Exchequer. Through the interest of the Earl of Sandwich however, he was soon nominated clerk of the acts of the navy, and he entered on the duties of his office early in June, 1660. That was the commencement of his connection with a great national establishment to which his diligence and acuteness were afterwards of the highest service. In this employment he continued till 1673; and during those great events, the plague, the fire of London, and the Dutch war, the care of the navy in a great measure rested upon him alone. The Duke of York being lord-high-admiral, Pepys was by degrees drawn into a close personal connection with him, and as he enjoyed his good opinion, he had also the misfortune to experience some part of the animosities with which he was loaded during the time of 'The Popish Plot.' The absence not only of evidence, but even of ground of suspicion, did not prevent Pepys being committed to the Tower (May, 1679) on the charge of being an aider and abettor of the plot, and he was for a time removed from the Navy Board. He was afterwards allowed, with Sir Anthony Deane, who had been committed with him, to find security in 30,000*l.*; and in February following, upon the withdrawal of the deposition against him, was discharged. He was soon replaced in a situation where his skill and experience could not be dispensed with, by the special command of Charles II., and was afterwards made secretary of the admiralty, which office he retained till the Revolution. James II. was sitting to Sir Godfrey Kneller for a portrait designed as a present to Pepys, when the news of the landing of the Prince of Orange was brought to him. The king commanded the painter to proceed and finish the portrait, that his friend might not be disappointed.

Upon the accession of William and Mary, Pepys lost his official employments; but he retired into private life without being followed either by persecution or ill will. He died May 26, 1703, and was buried in the church of St. Olave, Hart Street.

Pepys had an extensive knowledge of naval affairs. He thoroughly understood and practised music; and he was a judge of painting, sculpture, and architecture. In 1684 he was elected president of the Royal Society, and held that honourable office two years. As a patron of learning, it may be sufficient to say that he contributed no fewer than sixty plates to Willughby's 'Historia Piscium.'

To Magdalen College, Cambridge, he left an invaluable collection of manuscript naval memoirs, of prints, and antient English poetry, which has often been consulted by critics and commentators, and is indeed unrivalled in its kind. One of its most singular curiosities is a collection of English ballads in five large folio volumes, begun by Selden, and carried down to the year 1700. Percy's 'Reliques' are for the most part taken from this collection.

Pepys published 'Memoirs relating to the State of the Royal Navy of England for ten years, determined December, 1688,' 8vo., Lond. 1690, and there is a small book in the Pepysian library entitled 'A Relation of the Troubles in the Court of Portugal in 1667 and 1668, by S. P., Esq.,' 12mo., Lond. 1677, which Watt, in his 'Bibliotheca Britannica,' ascribes to Pepys.

His 'Memoirs' comprising his Diary from 1659 to 1669, and a selection from his private correspondence were edited by the present Lord Braybrooke, in 2 vols. 4to., Lond. 1825, republished in 5 volumes 8vo., Lond., 1828, from which and from Chalmers's account of him, most of the particulars in this notice have been derived.

PEPYSIAN LIBRARY. [MAGDALEN COLLEGE, CAMBRIDGE.]

PERÆA. [PALESTINE.]

PERAMBULATOR, an instrument in general use for measuring distances on roads, for settling disputes concerning the charges of the drivers of hackney-carriages, and for other purposes. It consists principally of a wheel upon which it runs, and an index which shows the number of turns of such wheel reduced into miles, furlongs, poles, and yards.

The carriage or stock is made of wood, and is about 3 feet long. At one end is a handle for the person who uses it, and the other is furnished with sockets in which the axle of the wheel turns: this end of the stock has the centre part removed, by which are left two arms between which the wheel works. Upon the stock and just in front of the handle is the dial-plate, with its two hands by which the distance is registered. The wheel is 8 feet 3 inches, or ½ pole, in circumference. Upon one end of the axis of this wheel is a small pinion, which works into a similar pinion at the end of a rod which passes up the stock or carriage to the works beneath the dial-plate. Motion is communicated by means of this rod to a worm or micrometer screw, which turns once round for each revolution of the carriage wheel of the perambulator. This worm works into a wheel of 80 teeth, which is moved forward one tooth for every ½ pole, and carries a hand or index, which makes one revolution for 40 poles or one furlong. On the axis of this wheel is a pinion of 8 teeth, which works into a wheel of 40 teeth, and on the axis of this second wheel is a pinion of 10 teeth, which moves a wheel of 160 teeth. This last wheel carries another hand, which makes one revolution for 80 of the former. These hands are arranged in the same manner as the hour and minute hand of a watch, so that the three circles on the dial-plate are all concentric. The first of these circles is divided into 220, and the second into 40, the number of yards and poles contained in a furlong; the figures on these circles are read off by the first-mentioned index, that which is attached to the wheel of 80 teeth. The third circle is divided into 80, the number of furlongs in 10 miles, and to this circle belongs the index attached to the wheel of 160 teeth. The distance is ascertained by reading off the figures in the reverse order in which the circles are given above: divide the number on the first circle by 8, and you will have the distance required in miles, furlongs, poles, and yards.

The instrument is furnished with a stop or strap, so that after the distance is measured, the perambulator may be conveyed without the index being altered.

Unlike the pedometer, it requires no regulating, and the only risk of its giving the distance incorrectly, if well constructed, is in passing over rugged and uneven roads, which will of course cause the index to show more than the true distance. In general however, for short distances, this error is very trifling.

When about to commence a measurement, the wheel should be turned round until the first-mentioned index points to 220 on the circle of yards. Some are provided with a click and racket, by which this may done with much less trouble than by the wheel.

There are other instruments for the same or similar purposes, bearing different names, as *waywiser* and *odometer;* but the construction of all of them is very similar.

Waywiser is the name generally given to that form of the instrument which is applied to a carriage, in which, by a slight adaptation to one of the wheels of the carriage, the instrument is made to register the number of turns of such wheel, in the same manner as the perambulator.

PERAME'LES. [BANDICOOT; MARSUPIALIA, vol. xiv., p. 437; and see further Professor Owen's paper 'On the Osteology of the Marsupialia' (*Zool. Proc.*, 1838).]

PERCEPTION is that power or act of the mind by which it holds communication with the external world. It is distinguished from *conception* by the circumstance that its objects are in every instance supposed to have an actual existence. We may conceive things that have no reality, but we are never said to perceive such things. Perception differs from *consciousness* in that it takes cognisance only of objects without the mind. We *perceive* a man, a horse, a tree: when we think or feel, we are *conscious* of our thoughts and emotions. It is further supposed in perception that the objects of it are present. We can *remember* former objects of perception, but we do not perceive them again until they are once more present. Besides the sense which has been explained, the term perception is sometimes analogically employed in common speech in reference to truths the evidence of which is certain. Thus we may perceive the truth of a mathematical proposition. But Mr. Hume is perhaps the only writer of eminence who designedly applies the word in a metaphysical disquisition with a meaning different from that which has been here assigned to it. By him it is applied indiscriminately to all the operations and states of the mind; passions being designated perceptions, and the acts of memory and imagination converted into so many acts of perception. Such latitude of phraseology confounds under one general name things essentially distinct, and tends to introduce vagueness and inaccuracy into a department of philosophical investigation where definiteness and precision are peculiarly indispensable.

The distinction between things *perceived* (αἰσθητά) and things *conceived* (νοητά) was familiar to the Greek philosophers and to their Latin expositors, of whom Cicero expresses the former class of things by the phrases 'quæ sunt,' 'quæ cerni tangive possunt;' and the latter by the phrases 'quæ tangi demonstrarive non possunt, cerni tamen animo atque intelligi possunt,' and gives examples of each. (*Top.*, v.)

The perceptive faculty is exercised through the instrumentality of the senses. We see by means of the eye, and hear by means of the ear, and so in reference to the other senses. An individual in whom these organs are wanting or defective, will either not perceive at all, or perceive imperfectly. In order to perception it is requisite that an impression should be made on the organ of sense, either by the direct application of the object, or through some medium that communicates with the object and the organ. Thus an immediate application is necessary with regard to the senses of taste and touch: but only an intermediate one with regard to those of sight, hearing, and smell. The impression made on the organs of sense affects the nerves, and is by them conveyed to the brain. The necessity of this communication is ascertained by observation. If the nerve appropriated to any organ be cut or tied hard, no perception takes place; and the same result is noticed in certain disordered conditions of the brain, even though the organs of sense and the nerves perform their respective functions. When however the conditions that have been specified are complied with, perception ensues.

Various theories have been formed to explain the functions of the nerves and brain in connection with perception. It was imagined by the antients that the nervous fibres are tubular, and filled with a subtile vapour named animal spirits; that the brain is a gland by which this æthereal fluid is secreted; and that by means of it the nerves perform their office. (Reid, *Essay* ii., ch. 3.) Des Cartes, who adopted this hypothesis, has described with great minuteness how all mental operations and movements are accomplished through the agency referred to. Dr. Briggs, Newton's instructor in anatomy, was the first who proposed a new doctrine on this point. He maintained that the nerves operate by vibrations, like musical chords, and thus conduct impressions to the brain. Newton himself (*Opt.*, qu. [illegible]) appears to have been inclined to a notion of this kind, and the suggestions relating to it thrown out by him as a query were afterwards amplified and defended by Hartley. The latter supposed that 'external objects impressed on the senses occasion, first in the nerves on which they are impressed and then in the brain, vibrations of the small and, as one may say, infinitesimal medullary particles;' and that these vibrations are excited, propagated, and kept up partly by the ether, that is, by a very subtile elastic fluid, partly by the uniformity, continuity, softness, and active powers of the medullary substance of the brain, spinal marrow, and nerves.' (*Observations on Man*, part i., prop. 4.) Both Des Cartes and Hartley believed that by the action of the nerves in the manner described by them, images of external objects were formed in the brain.

It is scarcely necessary to remark concerning these hypotheses that they are totally destitute of foundation. A sound theory must assign real and not imaginary causes for the phenomena which it professes to explain; and such causes must have a manifest competency to the effects ascribed to them. But the hypotheses in question entirely want both of these essentials. Who can prove the existence of the animal spirits of Des Cartes, or the vibrations of Hartley; or, granting their existence, who can show any correspondence between them and the formation of images in the brain? All we can affirm with certainty respecting the means of perception is, that, under certain circumstances, that is, when an impression is made on the bodily organ and communicated by the nerves to the brain, perception takes place. The impressions so communicated are the occasions of the mind perceiving, but we can assign no reason why it should do so under these circumstances invariably, and not under any other, further than that such is the constitution of our nature.

If the act of perception be examined, it will be found that we obtain by it a certain amount of information respecting the object perceived. We discover that it has particular qualities, as for example, that it is extended, that it has figure, that it is hard or soft, rough or smooth, &c. The notion thus formed may vary in respect of distinctness in all possible degrees. In the light of twilight a body is discerned more obscurely than in the full light of noon day, and more obscurely still in proportion as the darkness deepens. The notion we get of an object by perception is accompanied by an irresistible and immediate conviction of its real existence. An object may indeed be perceived so indistinctly as to leave us in doubt whether it be real or not. If it be very distant, or involved in darkness, this may happen. But when it is plainly perceived, there is, along with the perception, a perfect conviction of its reality. We can no more doubt of its existence than we can of our own. And this conviction is immediate. It is not the result of a process of reasoning founded on our perceptions, but inseparably connected with them, and as instantaneous as the assent rendered to axiomatic truths. It may be also remarked that the belief in the existence of the objects of perception is not more immediate and deeply rooted than is the belief that they exist externally to us. They do not seem to have their place in the mind itself, but to exist independently of it altogether. These statements accord with the universal experience of mankind, and may be verified by all who choose to bestow the slightest attention on the intimations of consciousness.

It would be a tedious as well as a useless task to dwell minutely on the numerous theories that have been framed of perception. In certain important particulars nearly all of them coincide; while in others, equally if not more important, they are for the most part at variance.

Democritus taught that perception was the result of the impressions made on the organs of sense by images (εἴδωλα which constantly emanated from bodies, and varied according to the conformation of their organs. (Plut., *Plac. Phil.* l. iv. ch. 8, &c.)

Plato, in the seventh book of his 'Republic' (ad init.) illustrates the manner in which we perceive objects by the figure of a cave, in which men lie bound, so that they can turn their eyes only to one part of it, where rays from a distant light stream in, and shadows of bodies, supposed to pass between them and the light, are beheld, the bodies themselves being invisible. He thus conceived that we perceive only the shadows of things, and not things themselves.

This opinion of Plato was substantially the same with that of his scholar Aristotle, and of the Peripatetics generally. Aristotle (*De An.*, l. iii. c. 2, 3) taught that as the senses cannot receive material objects themselves, they receive their images. These images are the only objects of perception in the mind. As impressed upon the senses, they are termed sensible species; more spiritualised, they become objects of memory and imagination, and are termed phantasms; still further refined, so as to be objects of science, they are named intelligible species.

The theory of Epicurus was little other than a modification of that of Aristotle. He supposed that bodies are continually sending off from their surfaces slender films or spectres of such subtlety that they easily penetrate by the senses to the brain. (Lucret., l. iv. v. 34, 46, &c.)

Locke employs an illustration of the manner of perception that appears to have been borrowed from that of Plato:—'Methinks,' he says, 'the understanding is not much unlike a closet wholly shut from light, with only some little opening left to let in external visible resemblances, or ideas of things without. Would the pictures coming into such a dark room but stay there, and lie so orderly as to be found upon occasion, it would very much resemble the understanding of a man in reference to all objects of sight and the ideas of them.'

The similitude of Locke, or rather of Plato, may be applied to all the systems of perception that have ever been formed, by merely substituting ideas, and, in the case of Hume, impressions, for what were anciently denominated species and phantasms. All these theories agree in maintaining that images are the only immediate objects of perception in the mind. Hume, Berkeley, and others indeed held that these are the exclusive objects; but the common hypothesis admits the existence of things of which these are but the representatives, and which we mediately discern. It may be sufficient to remark concerning these opinions, that they are diametrically opposed to the testimony of our own consciousness. Instead of informing us that images alone are the direct objects of our perception, consciousness intimates nothing regarding images at all. Unless its representations are altogether deceptive, it is not things within the mind, but things external to it, that we perceive; not images of objects, but the very objects themselves. This is testimony to which we yield instinctive credence. It is too urgent and unquestionable to be set aside by reasoning of any kind, far less by reasoning based upon certain imagined relations subsisting between matter and spirit which we are incapable of apprehending, and the application to mind of laws which apply solely to the objects of physical investigation.

One observation, intentionally deferred, remains still to be made respecting perception, namely, that it is greatly modified by habit and by the cultivation and development of the other powers. Thus the perceptions of a man and those of a child, both contemplating a piece of complex machinery, the one being aware of its principles and arrangements, the other completely ignorant of them, must in many respects considerably differ. In like manner the perceptions of a blind man, by means of those organs of sense which are unimpaired, are distinguished in many particulars from those of the individual who has never been without the faculty of vision. Numerous instances of a similar kind might easily be specified. A full account of acquired perceptions, such as those alluded to, is still a desideratum in this department of philosophical inquiry.

PERCH or **POLE**. This measure, though now mostly used as a square measure (a perch usually meaning a square perch, or a square of a perch in length and breadth), was originally a measure of length, arising out of the custom of measuring small portions of land by a staff or pole. The word *pertica*, from which it comes, means a wooden staff, and the pole with which land was measured not only differed very much in different countries, but in different parts of the same country. Ducange and his editors find records of the use, in different parts of England and France, of perches of 7½, 10 (the oldest English), 12, 15, 16, 18, 20, 21, 22, 25, and 27 feet. Here is but another instance (as in Mile and League) of the tendency of measures to lengthen. Forty perches (*quarantena*), under the name of forty-long or furlong, became a common measure of length; and a piece of land forty perches long and one deep, was called *perticata*. (Spelman, cited by Ducange.) Thus the perch and furlong, though afterwards received into the system of measures which ends with the mile, originally formed no part of it whatever. [Mile.*]

By an early statute, entitled 'Compositio Ulnarum et Perticarum,' the perch was fixed at 16½ feet, or five yards and a half; and four perticatæ (though that word is not used) were defined as an acre.

A perch is the quarter of a chain, and a square perch contains 30¼ square yards.

PERCHE, LE, a province of France, united, before the Revolution, with Maine, into one military government. It was bounded on the north by Normandie, on the north-east by the Ile de France, on the east and south by Orléanais, and on the west by Maine. It was subdivided into Le Grand Perche, or Le Haut Perche (Great or Upper Perche), of which Mortagne was the capital; Le Perche Gouet, or Le Bas (Lower) Perche, of which Montmirail was the capital; Les Terres Françaises, of which Tour-Grise-de-Verneuil was the capital; and Les Terres Demandées, or Thimerais, of which Châteauneuf-en-Thimerais was the chief town. Perche is now comprehended in the departments of Orne, Sarthe, and Eure et Loir.

Le Perche was under the government of its own counts from the year 940; but the original county was not equal in extent to the province of later times. Having fallen to the crown, the county was given with that of Alençon to Pierre, one of the younger sons of St. Louis (A.D. 1269); but these counties having on his death reverted to the crown, they were again bestowed on Charles de Valois, brother of Philippe le Bel (A.D. 1293), in whose family they long continued. In 1301 they were separated, Perche going to a younger branch of the family; but in 1404 they were again united.

In the reign of François I. the county was, on the death of the last male heir, seized by the crown, but the justice of the claim was for a while disputed. During the dispute the widow of the late count was allowed to possess the county, but it was afterwards annexed to the crown domains.

PERCIDÆ, or *Percoïdes* of Cuvier, a family of Acanthopterygious fishes, of which the common perch may be regarded as the type, that is to say, the fishes of this great group, which ought perhaps to be regarded as an order rather than a family, all more or less approach the common perch in general form: they have the body covered with scales whose outer surface is more or less rough, and the free margins of which are denticulated; the operculum and preoperculum are variously armed with spines and denticulated at the outer margin; they not only have teeth in both jaws, but the vomer and palatine bones are also furnished with them: the number of rays in the branchiostegous membrane varies from five to seven; they never fall short of the lower nor exceed the higher number. The flesh of these fishes is generally well flavoured and wholesome. They inhabit both salt and fresh water.

The first division of the Percidæ, according to Cuvier, comprises all those species which have the ventral fins placed under the pectorals, five soft rays in the ventral fins, seven branchiostegous rays, and two dorsal fins. This section includes the following genera:—

1. *Perca* proper, in which the preoperculum is denticulated; the operculum is produced behind into a flattened spine; the infra-orbitals are obscurely denticulated, and the tongue is smooth. Example, the common perch (*Perca fluviatilis* of Linnæus). (Yarrell's *British Fishes*.) Closely allied to this is the *P. italica* of Cuvier and Valenciennes, a species found in tolerable abundance in some parts of Italy; it differs from the *Perca fluviatilis* in being of a shorter and deeper form, and is destitute of the black bands. Several true perches are found in North America; species have also been discovered in Java and New Zealand: it is highly probable therefore, from the extensive geographical range of the perches proper thus exhibited, that very many species still remain to be discovered.

---

* In that article [illegible] 'perticata' is erroneously written for 'pertica.'

2. *Labrax* (Cuv. and Val.) differs chiefly from the true perches in having the infra-orbitals destitute of denticulations as well as the suboperculum; the operculum (which, as well as the preoperculum, is entirely covered with scales) has two spines on the posterior part, and the tongue is furnished with minute teeth. [LABRAX.]

3. *Lates* (Cuv. and Val.), a genus also closely allied to Perca proper, in fact differs only in having the infra-orbitals more deeply denticulated as well as the humerals; large spines are observable on the angle of the preoperculum; the anterior dorsal is shorter and higher than in the perch; the tongue is smooth, as in the last-mentioned fish.

The fishes of this subgenus are usually of large size, good eating, and are chiefly found in the rivers in the warmer parts of the Old World.

4. *Centropomus* (Lacép.) includes those perch-like fishes whose operculum is produced behind, but the produced part is rounded at the apex; in the fins and denticulated preoperculum they resemble the perch. In the only species of this genus hitherto discovered the head is more pointed than in the preceding genera. [CENTROPOMUS.]

5. *Leucioperca* (Cuv. and Val.) differs from both the preceding genera in having larger sharply-pointed teeth intermixed with the ordinary small teeth, the form of the body is more elongated, and the first dorsal fin is large. The *L. Sandra*, C. and V., is found in the rivers and lakes of the north-eastern portions of Europe, and is known to the Germans by the names of Sander, Sandel, or Sandat; it is the Schil of the Austrians, and the Nagmaul of the Bavarians. A second species, the *L. Volgensis* of Gmelin, inhabits the rivers of Russia, and a third is found in the United States.

6. *Huro* (Cuv. and Val.): this genus is founded on a fish described by Dr. Richardson, which, with most of the essential characters of the perches, differs in having the opercula simple, a character in fact not found in either of the other genera here described. The species alluded to inhabits Lake Huron, and is called by the inhabitants the Black Bass: it is considered one of the best flavoured fishes of that lake.

7. *Etelis* (Cuv. and Val.): in this genus, as in *Leucioperca*, there are larger teeth intermixed with the ordinary minute ones, but here the larger teeth are confined to the jaws, and are not found intermixed with the palatine teeth, as in *Leucioperca;* the operculum is terminated by two spines, whilst in the genus just mentioned it is simple. Only one species of Etelis is known; its body is elongated, the muzzle is rather obtuse, the eyes very large, and the outer rays of the tail-fin are elongated; this fish (the *E. carbunculus*, Cuv. and Val.) is also remarkable for its brilliant red colour, and is adorned with longitudinal golden stripes. It is found in the region of the Seychelle Islands, north of Madagascar.

8. *Niphon* (Cuv. and Val.): this genus is founded on a single species found in the Japanese Sea, and is remarkable for the large spines with which the opercula are armed; the preoperculum is strongly dentated at its margin and furnished with a long and powerful spine at its angle, and the operculum has three of these large spines; the first dorsal is large, and its spinous rays are strong; the body is somewhat elongated, and the head is pointed. The authors last quoted apply to this species the name *N. spinosus*.

9. *Enoplosus* (Lacépède) is also founded upon a single species (from Australia) originally described in White's 'Journal of a Voyage to New South Wales,' in which work the fish is mistaken for a *Chætodon*, no doubt from its short, deep, and compressed form, and produced muzzle. Like the true perches, it has two dorsal fins, but these are much extended in the vertical direction; the third ray of the first dorsal is very large, and long, and the six anterior rays of the second dorsal are also much elongated; the infra-orbital is denticulated, and so is the preoperculum which is moreover furnished with a strong spine; the operculum is simple, *i.e.* destitute of spines: it is the *Enoplosus armatus* of Cuv. and Val., a fish of small size, being seldom more than eight or ten inches in length; the body is adorned with seven or eight black bands on a silvery ground: some of these bands however are abbreviated.

10. *Diploprion* (Kuhl and Van Hasselt), like the two preceding genera, contains but one species (*Diploprion bifasciatum* of the authors just quoted). This fish is of a short and high form, having a large head somewhat obtusely terminated in front; its colour is yellow; a broad black vertical mark runs through the eye, and a still broader band crosses the body. The infra-orbital is entire, the preoperculum is denticulated, and the operculum is armed with three strong spines. It is found off the coast of Java.

11. *Apogon* (Lacépède). In this genus the first and second dorsal fins are small in antero-posterior extent, and widely separated; the general form of the body is ovate, but somewhat suddenly less deep behind the second dorsal; the head is without scales, large, and obtuse in front; the scales are very large and easily dislodged; the preoperculum is denticulated. Many species of this genus inhabit the Indian seas, but that which is most generally known (the *A. rex-mullorum*) is found in the Mediterranean. It is a small fish, rarely more than five or six inches in length, and of a golden red colour, with a black spot on each side at the base of the tail-fin; there is also generally a spot of the same colour near each angle of this fin, another on the posterior dorsal, and a brown tint between the eye and the tip of the muzzle. Besides these larger blotches, the body is marked with minute black specks.

12. *Cheilodipterus* (Lacépède) has larger pointed teeth mixed with the ordinary ones; the preoperculum is denticulated, and the operculum is entire. [CHEILODIPTERUS.]

13. *Pomatomus* (Cuv. and Val.). In this genus the dorsal fins are small in antero-posterior extent, and widely separated; the second dorsal fin and the anal fins are thick and covered with small scales; the body is somewhat elongated and thick; the head is large, and the eyes very large; the opercula are covered with scales; those on the body are large and easily dislodged.

Only one species of this genus is known, the *Pomatomus telescopium* of Risso, and this is said to be exceedingly rare, living, it appears, in very deep water. Risso states that at Nice, where the species has been found, only two specimens were taken during thirty years. The individual to which MM. Cuvier and Valenciennes's description is taken was about twenty inches (French measure) in length. The colour of this fish is brownish-violet, with blue and red reflections. The authors just mentioned do not appear quite satisfied as to the true affinities of this genus.

14. *Ambassis* (Cuv. and Val.). This genus is founded upon a small fish found off the coast of the Isle of Bourbon; its principal characters consist in the double series of denticulations on the lower portion of the preoperculum, a denticulated infra-orbital, a protractile mouth, and a small recumbent spine in front of the first dorsal fin, the point of which is directed forwards. In the form of the body it approaches the common perch. It is the *Ambassis Commersonii* (Cuv. and Val.): a second species is found off the Malabar coast, and there are several in the Indian seas, most of which are described by Hamilton, in his 'Account of the Fishes found in the River Ganges and its Branches,' under the generic name *Chanda*.

15. *Aspro* (Cuv. and Val.). The species of this genus have the body elongated, slender, and approaching the cylindrical form; the eye is moderate, and placed in the upper part of the head; the muzzle is obtuse, and the mouth is rather small; the first and second dorsals are widely separated, and the ventral fins are large. Two species are known; one found in the Rhone, the Saône, and some other rivers of France, is about six or seven inches in length, of a reddish or yellowish brown colour, and has four black bands extending across the back. It is the *A. vulgaris* of Cuv. and Val., and *Perca aspera* of Linnæus. The second species of Aspro (the *A. Zingel*, C. and V.), found in the Danube and its tributaries, attains a much larger size.

16. *Grammistes* (Cuv. and Val.). The species composing this genus have small scales; their operculum and preoperculum are armed with spines, but not denticulated; the anal fin has no distinct spinous rays; the body is usually moderately deep, somewhat compressed, and suddenly less deep towards the tail; the head is moderately large, the eyes moderate, and the first and second dorsal fins are placed near each other.

The *Grammistes orientalis* (Cuv. and Val.) is of small size; its colour is deep brown, and the head and body are adorned with numerous longitudinal white lines; the number of these lines, it would appear, varies in different individuals. Inhabits the Indian seas. This genus terminates the first division of the *Percoides* of Cuvier and Valenciennes, a section sufficiently extensive both as to genera and species, and (if we except a few species) in all probability a natural one.

The second division comprises those species in which the first or spinous dorsal is united with the second or soft-rayed dorsal, so as to form one continuous fin, and is composed chiefly of the great genus *Serranus*. [Serranus.]

The third division embraces those Percoid fishes which differ from the preceding in having less than seven branchiostegous rays. The principal genera contained in this division are noticed under the proper heads; like the *Serrani*, they have the first and second dorsal fins united, but there is often a deep emargination between the spinous and soft-rayed portion. The fourth division is composed of such species as have more than five soft rays to the ventral fins, and more than seven branchiostegous rays. It contains the following genera:—

1. *Myripristis* (Cuv. and Val.), or fishes having the above characters, combined with a short deep and somewhat compressed form of body, which is suddenly contracted near the tail, and furnished with large and strongly serrated scales, the head large, the mouth also large, and the eye moderate; the preoperculum is denticulated, and the operculum is serrated, and produced into a strong and large spine; there is a strong spinous ray in front of the ventral fins, and three or four spines in front of the anal, one of which at least is large: the first and second dorsals are almost separated by a deep emargination. The species of this genus inhabit the tropical seas of both the old and new world, and are usually of small size, seldom exceeding seven or eight inches in length; their colouring is usually very brilliant.

2. *Holocentrum* (Cuv. and Val.). This genus, like the last, contains fishes of very brilliant colouring, the prevailing hue being shades of red. It differs chiefly from *Myripristis* in having a strong spine on the angle of the preoperculum: the operculum is strongly serrated, and armed with large spines. The species are found in the seas of tropical climates.

3. *Beryx* (Cuv. and Val.). In this genus there is no spine on the angle of the preoperculum, and it moreover has but one rather short dorsal fin, which is not emarginated. [Beryx.]

In this division MM. Cuvier and Valenciennes also place Dr. Shaw's genus *Trachichthys*, founded on a fish from the coast of New Holland (*T. Australis*, Shaw), which apparently differs chiefly in having a double keel on the abdomen, which is strongly serrated; the preoperculum is armed with a spine.

In the fifth division of Percoïd fishes the ventral fins are placed in advance of the pectorals. It contains the genera *Trachinus*, *Percis*, *Pinguipes*, *Percophis*, and *Uranoscopus*.

In the sixth and last division the ventral fins are placed behind the pectorals. It comprises the genera *Sphyræna*, *Paralepis*, and *Polynemus*.

PERCIVAL, THOMAS, M.D., well known for his writings on medical and moral subjects, was born at Warrington in Lancashire, in the year 1740. He was brought up under the care of an elder sister, having lost both his parents at an early age, and received his education at the grammar-school of his native town. Having chosen the medical profession, he was sent to the university of Edinburgh, where he studied for three years. He afterwards visited London and Leyden, and having spent some time in both of these places, he took his doctor's degree at Leyden in 1765. In 1767 he settled in practice at Manchester, and quickly met with great success, being highly respected by all classes for his professional talents as well as for his high moral and religious worth.

Amidst his professional avocations, he found time for the pursuit of many experimental inquiries on subjects connected with medicine; and possessing considerable eloquence, he was fond of scientific discussion, and was mainly instrumental in the foundation of the Manchester Philosophical Society. This institution originated in a weekly meeting of literary men, who used to assemble at Dr. Percival's house for the purpose of conversing and reading papers on medical and scientific subjects. A number of these communications, many of them by Dr. Percival himself, were collected and published in 1781, and were so well received, that a regular organized 'Literary and Philosophical Society' was established, of which Dr. Percival was elected the first president, and which has since numbered among its members many distinguished persons, and produced many volumes of valuable Transactions.

Dr. Percival endeavoured to establish public lectures on mathematics, commerce, and the fine arts in Manchester, but was not able to succeed. He devoted a considerable portion of his time during the later period of his life to the study of moral philosophy, and he published several popular works on this subject. In his religious tenets he was a strict dissenter from the church of England, but was very temperate and unobtrusive in his opinions. He died, universally respected by the inhabitants of Manchester, on the 30th August, 1804.

Dr. Percival published many works. Most of his earlier writings (which were chiefly on medical and philosophical subjects, such as the therapeutical actions of medicines, on which he made many experiments) appeared in the form of memoirs in the 'Philosophical Transactions' of London or Manchester, and were afterwards collected and published in one volume, which came out in 1767, London, 8vo., with the title of 'Essays, Medical and Experimental.' To this two other volumes were afterwards added, one in 1773, and the other in 1778. These essays went through several editions, and acquired the author considerable reputation. One of them is devoted to the consideration of the properties of the different preparations of cinchona. Dr. Percival arrived at the conclusion that an aqueous solution of the bark possessed the greatest efficacy; subsequent experience however has not supported this opinion. Another of these essays contains an excellent and complete account of the medical properties of columba root; but the most interesting of them, which was first published in the third volume of the 'Manchester Philosophical Transactions,' consists of a detail of a number of researches on the mode of action of medicines on the blood and other animal fluids. Besides the 'Essays,' we may mention some 'Observations and Experiments on Water,' Lond., 1768, 8vo.; 'Observations on the Poison of Lead,' 1774, 8vo.; 'Moral and Literary Dissertations,' Warrington, 1784, 8vo.; 'A Father's Instructions, consisting of Moral Tales, Fables, and Reflections, designed to promote the Love of Virtue,' London, 1788, 8vo.; 'Medical Ethics, or a Code of Institutes and Precepts adapted to the Professional Conduct of Physicians and Surgeons,' Manchester, 1803, 8vo. This work was republished with additions in 1827. Besides what we have mentioned, Dr. Percival wrote many other papers on different subjects. All his works were collected and published together after his death by his son, in 4 vols. 8vo., London, 1807. To this edition is prefixed a memoir of his life and writings, and a selection from his literary correspondence.

PERCNO'PTERUS. [Vulturidæ.]

PERCUSSION, CENTRE OF, the point of a system which moves about a fixed axis, at which a force may act in such a manner as to produce no pressure on the axis. Its distance from the axis is the same as that of the centre of oscillation. [Oscillation.]

PERCUSSION, in medicine, is the method of eliciting sounds by striking the surface of the body, for the purpose of determining the condition of the organs subjacent to the parts struck.

This means of diagnosis was first employed by Avenbrugger in the middle of the last century; it was afterwards extensively adopted by Corvisart in investigating the diseases of the heart, but its value, like that of all the other branches of auscultation, was not fully appreciated till Laennec made them the subject of his peculiar study. Since his time its value has been considerably enhanced by the labours of M. Piorry.

Everybody knows that when a hollow body is struck, there is a vibration produced in the air within it, which being communicated through the walls to the external air, produces a ringing sound, whose tone varies with the size of the hollow body, the material of which it is composed, and many other circumstances; but that if the same body be filled with a fluid or a nearly solid substance, no other sound is produced than that which results from the striking together of two solid bodies of the same materials, as the wall of the cavity and the substance with which it is struck. On these circumstances the practice of percussion is based. If any part of the body beneath which there is a hollow organ, or one containing air in tubes, be struck, a resonance is produced; if any part which lies over a solid or a fluid be similarly struck, the sound emitted is merely the dull noise of two solid and rather soft bodies.

The modes of employing percussion are various. The simplest and most convenient is to place one finger of the left hand flat upon the part to be examined, and to strike it lightly but rather sharply with the ends of the three first fingers of the right hand set close together on the same level. Instruments called pleximeters have been invented by M. Piorry and others, and are sometimes, though now rarely, used; they are composed of small plates of cork, india-rubber, light wood, or ivory, which being held either by their edges or by a handle, are placed on the part to be examined, and struck with the fingers, or with a small hammer. There is however no important advantage to be derived from them, and the use of the fingers alone is much more convenient. It is indeed sufficient to strike the unguarded surface with the ends of the fingers; but this method has no advantage to compensate for the pain which it sometimes produces, and which is effectually prevented by the intervention of the finger of the left hand. Care should be taken that the blows are always given with the same or an exactly estimated degree of force, and that they should fall perpendicularly to the surface of the organ to be examined.

Percussion is chiefly employed in the diagnosis of diseases of the lungs, heart, and abdominal organs. The particular symptoms which are obtained by it in each disease are detailed, with their other signs, in the articles devoted to each. [PHTHISIS; HEART, DISEASES OF, &c.] It will be sufficient here to state the general rules to be observed.

The lungs being chiefly composed of tubes and cells filled with air, there is a certain degree of resonance when the chest over any part of them is struck; but the character of the sound varies somewhat both in intensity and in tone according to the part of the chest examined, and the thickness and softness or hardness of its walls: in all parts however, when the lungs are healthy, there is resonance. When however the lung is covered by fluid, or has the quantity of air in it lessened by obstruction of the air-tubes, or by deposits of fluid or solid substances in or around the cells, the resonance of the chest directly over the part affected is diminished or entirely lost, and in extreme cases the only sound obtained by percussion is the dull sound of the contact of the fingers with the wall of the chest. When, on the other hand, the air-cells are dilated, and the lungs contain a greater proportion of air than is natural to them, as in emphysema of the lungs, the resonance of the chest is in a corresponding degree increased. The various degrees between perfect dullness, such as occurs when the lung is covered by fluid [HYDROTHORAX], or rendered solid by inflammation [LUNGS, DISEASES OF], or by tubercular deposition [PHTHISIS], and the highest degree of resonance in emphysema, are numerous, but are of course appreciable only by a very practised ear and hand. To them the evidence they afford is scarcely less valuable than that obtained from the use of the stethoscope, with which the practice of percussion should, in all diseases of the chest, go hand in hand.

In the healthy state, the chest, when struck over the region of the heart, emits a duller sound than that which proceeds from the rest of its walls. In the natural size of the heart this region occupies a space of an inch and a half or two inches square, situated just to the left of the sternum, at the level of the fourth and sixth ribs. When either the heart itself is enlarged, or a quantity of fluid is accumulated in the pericardium, the extent of this less resonant region is increased in a corresponding degree; but the changes of sound which it emits depend greatly on the coincident condition of the lungs, and the extent to which their anterior margins overlap the front of the heart.

By percussion on the abdomen one may obtain information, approximating to truth, of the size of all the solid organs, by the extent of the dullness of sound in their respective regions; and of the degrees of inflation, and even of the nature of the contents of the digestive canal and the peritoneal cavity, whether solid, liquid, or aeriform; but the evidence thus obtained is on the whole less definite in the diseases of the abdominal organs than in those of the heart and lungs. The best account of diagnosis by percussion is in the works of M. Piorry.

(*De la Percussion mediate*, Paris, 1828; and *Du Procedc operatoire*, &c., 1830.)

PERCY, THE FAMILY OF, one of the most illustrious in England.

Percy was in use as a name of addition in England as early as the reign of the Conqueror. This fact we learn from a most indisputable authority, Domesday Book, where we find William de Percy holding numerous manors in the counties of Lincoln and York. It is presumed that he was one of the persons who accompanied the duke of Normandy, and as there are three places called Percy in Lower Normandy, it is a very reasonable supposition that the name was derived from residence at one of those places.

From this William descended several persons of the name who occur in the chronicles and as benefactors to the church, till the reign of Henry II., when another William de Percy died without male issue, leaving two granddaughters (children of a son who died before him) his heirs. These great heiresses made splendid marriages; Maud marrying the earl of Warwick, and Agnes, Josceline of Louvain, a brother of Adeliza, the second wife of king Henry I. By the death of Maud, without issue, the descendants of Agnes became the sole representatives of the first race of Percys, and they adopted the name of Percy as their name of addition.

This Josceline, who was the male ancestor of the Percys of whom we read so much in the English history, was of the family of the dukes of Brabant, one of the most illustrious in Europe. One of his sons was active among the barons at the time when King John granted the great charter, and his descendants, for two centuries after his time were conspicuous on all occasions when the barons acted as a body. It was a Henry de Percy who, in the reign of Edward I., acquired Alnwick and other lands in Northumberland, which thenceforward became the county to whom the Percys are particularly supposed to belong. Warkworth was granted to his son.

It is impossible to do more than touch on a few of the more prominent circumstances. Another Henry de Percy, in the reign of Edward III., married Mary of Lancaster, daughter of Henry (Plantagenet) earl of Lancaster, grandson of King Henry III. This marriage brought the succeeding Percys into near alliance with the crown, and the two sons who issued from it were made the one earl of Northumberland, the other earl of Worcester. Both these titles were conferred by King Richard II.

The title of earl of Worcester soon ceased in this family, the earl having engaged in the rebellion against King Henry IV., and being beheaded at Shrewsbury soon after the battle which was fought near that town. In the same battle Henry Percy (Hotspur), nephew of the earl of Worcester, son to the elder brother, the earl of Northumberland, was slain; and the earl of Northumberland himself, uneasy under the rule of his near relative Henry IV., was slain by the posse comitatus of Yorkshire in 1408.

The son of Hotspur was restored by Henry V. to the title of earl of Northumberland. He was slain at the battle of St. Alban's in 1455, and his son, the third earl, fell at the battle of Towton, 1460. The fourth earl was slain in a tumult at Thirsk, in 1489. The fifth earl died in peace, in 1527. He is the earl whose 'Household Book' is published, a volume which exhibits very much of the customs of the time in the houses of the great. The sixth earl, his son, died also in peace, in 1537.

As the sixth earl died without issue, there was fear lest the honours of this great family should be lost, for the next heir male descended from an attainted member of the family, and so could not succeed. It seems to have been intended that the title of Northumberland should pass from them, for John Dudley, earl of Warwick, was made, by King Edward VI., duke of Northumberland. His honour was however short-lived, and he being dead and attainted, Queen Mary restored the male heir of Percy to the earldom of Northumberland. But the same evil fate pursued him. He engaged in rebellion against Queen Elizabeth, and was put to death at York, in 1572. His brother Henry Percy succeeded, in virtue of limitation in the patent of restoration granted by Queen Mary. This earl came to a violent end, being imprisoned in the Tower, and found dead in his bed, shot with three pistol-bullets. This was in 1585. After him were several other earls of Northumberland of this family, the last of whom was earl Josceline, the eleventh earl, who died at Turin, in 1670, being then aged twenty-six. In this earl the principal male line of Percy became extinct. There were living at the time persons who believed themselves to be of the blood, and some of them indisputably were so, but only one of them, a trunk-maker, at Dublin, whose descent is very dubious, prosecuted any claim to the honours of the family, and his claim was disallowed.

Josceline, earl of Northumberland, left an only daughter and heir, lady Elizabeth Percy. This great lady married first, Henry Cavendish, earl of Ogle, who thereupon took the name of Percy. He died very soon after the marriage. She was then contracted to Thomas Thynne, Esq., who was assassinated just at the time in Pall-Mall. She then married, in 1682, Charles Seymour, duke of Somerset, who undertook to relinquish his hereditary name, and to call himself and his posterity by the name of Percy. Such was the determination to keep up the splendid name. Some time after however the duke was released from the obligation, and resumed his name of Seymour.

The duke of Somerset had Algernon, his son and heir, duke of Somerset, who was created, in 1749, earl of Northumberland, with remainder to his son-in-law Sir Hugh Smithson, who had married lady Elizabeth Seymour, his only daughter and heir.

Sir Hugh Smithson became earl of Northumberland on the death of his father-in-law, when he took the name of Percy. In 1766 he was created duke of Northumberland. From him descend the three existing peers of the family of Percy, namely, the duke of Northumberland, the earl of Beverley, and lord Prudhoe.

A large history of the family may be read in Collins's 'Peerage,' especially in the edition of 1779; but there are valuable parts of the history in earlier editions, which are there left out.

PERCY, THOMAS, D.D. (born 1728, died 1811), an elegant scholar, and a prelate of the Irish church, was the son of a grocer at Bridgnorth in Shropshire, where he was born. He affected to be considered of the noble house of which we have been speaking, or it has been affected for him; but his better and surer honour is that he was the maker of his own fortunes, and by his valuable writings and the honourable discharge of his episcopal duties has reared for himself a high and permanent reputation. He was educated at Christ-Church, Oxford, and early in life obtained the vicarage of Easton Mauduit, on which he resided, and the rectory of Wilby.

He began his literary career by the publication of what purports to be a translation from the Chinese of a novel, together with other matters connected with the poetry and literature of that people. This is a translation by him from a Portuguese manuscript. This was soon followed by another work, entitled 'Miscellaneous Pieces relating to the Chinese.' He next published translations from the Icelandic of five pieces of Runic poetry. These appeared in 1761, 1762, and 1763. In 1764 he published a new version of 'Solomon's Song,' with a commentary and notes; and in 1765, a 'Key to the New Testament,' which has been reprinted several times. In the same year, 1765, appeared the work by which he is best known, and which is indeed one of the most elegant and pleasing works in the whole range of English literature, to which he gave the title of 'Reliques of Ancient English Poetry.' It contains some of the best of the old English ballads; many very beautiful lyrical pieces by the poets of the Elizabethan period and the age immediately succeeding; a few extracts from the larger writings of the poets of those periods, and a few lyrical pieces by modern writers. Each piece is well illustrated. There have been several editions of it, the last of which is in a cheap form, in one octavo volume.

The publication of so popular and pleasing a work naturally drew attention to the author or editor, and particularly the duke and duchess of Northumberland took notice of one who bore their name, and in or about 1765 he was appointed domestic chaplain in the family. In 1769 he was made one of the chaplains of the king; in 1778, dean of Carlisle; and in 1782, bishop of Dromore.

During the period of which we have been speaking he continued his literary labours. In 1770 he printed the 'Northumberland Household Book,' and a poem, the subject of which is connected with the history of the Percy family, called 'The Hermit of Warkworth.' In the same year appeared his translation, with notes, of 'The Northern Antiquities,' by Mons. Mallet. The assistance which he gave to other authors is often acknowledged by them, and especially by Mr. Nichols, in several of his works.

When he became an Irish bishop, he thought it his duty to devote himself almost entirely to his diocese. He resided from that time almost constantly at the palace of Dromore, where he lived greatly respected and beloved. After a life in the main prosperous and happy, he tasted of some of the afflictions of mortality. In 1783 he lost an only son. His eyesight failed him, and he became at length totally blind. He died at the palace of Dromore, September 30, 1811.

PERDICCAS, the son of Orontes, was one of the generals of Alexander the Great, to whom that conqueror on his deathbed delivered his royal signet, thus apparently intending to designate him as protector or regent of his vast empire. Alexander's wife Roxana was then far advanced in pregnancy, and his other wife, Statira, the daughter of Darius, was supposed to be in the same situation. In the mean time the Macedonian generals agreed to recognise as king Arrhidæus, a natural son of Philip, a youth of weak intellects, with the understanding that if the child of Roxana should prove a son, he should be associated in the throne with Arrhidæus. Perdiccas contented himself with the command of the household troops which guarded the person of King Arrhidæus, but in that capacity he was in reality the guardian of the weak king and the minister of the whole empire. He distributed among the chief generals the government of the various provinces, or rather kingdoms, subject to Alexander's sway: Antipater had Macedonia and Greece; Lysimachus, Thrace; Eumenes, Paphlagonia and Cappadocia; Antigonus, the rest of Asia Minor; and Ptolemy had Egypt. For the distribution of the other provinces see Justinus (xiii. 4). Roxana, being soon after delivered of a son, who was called Alexander, became jealous of Statira, from fear that the child she was pregnant with might prove a rival of her own son; and in order to remove her apprehensions, Perdiccas did not scruple to put Statira to death. He endeavoured to strengthen himself by an alliance with Antipater, whose daughter he asked in marriage, while at the same time he was aspiring to the hand of Cleopatra, Alexander's sister. Olympias, Alexander's mother, who hated Antipater, favoured this last alliance. Antipater, having discovered this intrigue, refused to give his daughter to Perdiccas, who in the end obtained neither. The other generals, who had become satraps of extensive countries, considered themselves independent, and refused to submit to Perdiccas and his puppet kings. Perdiccas above all fearing Antigonus as the one most likely to thwart his views, sought to destroy him, but Antigonus escaped to Antipater in Macedonia, and represented to him the necessity of uniting against the ambitious views of Perdiccas. Antipater, having just brought to a successful termination a war against the Athenians, prepared to march into Asia, and Ptolemy joined the confederacy against Perdiccas. The latter, who was then in Cappadocia with Arrhidæus and Alexander the infant son of Roxana, held a council, in which Antipater, Antigonus, and Ptolemy being declared rebel against the royal authority, the plan of the campaign again them was arranged. Eumenes, who remained faithful Perdiccas, was appointed to make head against Antipat and Antigonus, while Perdiccas, having with him the tw kings, marched to attack Ptolemy in Egypt. He was however unsuccessful, owing to his ill-concerted measures: he lost a number of men in crossing a branch of the Nile, and the rest became discontented, and in the end Perdiccas was murdered in his tent, B.C. 321, after holding his power for two years from the death of Alexander. Eumenes, who had been more successful against Antipater in Asia Minor, carried on the war for some years, but was at last betrayed by his own soldiers into the hands of Antigonus, who put him to death. [EUMENES; ANTIGONUS.]

The administration of Perdiccas after the death of Alexander is treated at some length by Droysen, 'Geschichte der Nachfolger Alexanders.'

PERDICCAS. [MACEDONIA.]

PERDICIDÆ, the name of a family, or, according to some, a subfamily of *Tetraonidæ*; in the latter case the form should be *Perdicinæ*.

The genus *Perdix*, Briss., in Mr. Swainson's arrangement, is made to contain the subgenera *Perdix* (Partridges); *Chætopus* (Francolins); *Coturnix* (Quails); *Ptilopachus*, Sw.; and *Ortyx*, Stephens.

The Prince of Musignano (*Geographical and Comparative List*) makes *Perdicinæ* the first subfamily of the *Tetraonidæ*, containing the genera *Lophortyx*, Bonap.; *Ortyx*, Stephens; *Francolinus*, Briss.; *Perdix*, Bonap.; *Starna*, Bonap.; and *Coturnix*, Temm. It must be borne in mind that this list relates only to the birds of Europe and North America.

The *Perdicinæ*, according to Mr. G. R. Gray's arrangement, form also the first subfamily of the *Tetraonidæ*, and consist of the following genera:—*Ithaginis*, Wagler; *Francolinus*, Briss.; *Perdix*, Lath.; *Starna*, Bonap.; *Lerwa*, Hodgs.; *Arboricola*, Hodgs.; *Coturnix*, Briss.; *Ptilopachus*, Swains.; *Liponyx*, Vieill. [ROULOUL]; *Ortyx*, Stephens; *Lophortyx*, Bonap.; *Callipepla*, Wagler; *Odonto-*

phorus, Vieill.; and *Tetraogallus* (Lophophorus of Jardine and Selby), J. E. Gray.

Geographical Distribution.—The birds of this group are widely spread; no quarter of the globe being without some of the family, all of which are more or less esteemed as affording a nutritious and sapid food to man.

We now proceed to lay before the reader some of the leading forms among this extensive race; as far as our limits will permit.

Perdix (Ray—*Starna*, Bonap.).

Example, *Perdix cinerea; Starna cinerea*, Bonap. This, the well known object of every European partridge-shooter, is too familiar to require description.

It is the *Perdice*, *Pernisette*, *Pernigona*, and *Starna* of the Italians; *Perdris*, *Perdris gringette*, *Perdris griesche*, *Perdris grise*, *Perdris Gouache*, and *Perdris des Champs* of the French; *Rebhuhn* of the Germans; *Coriar* of the antient British;* *Partridge* of the modern British.

Localities.—Mr. Gould (and he is corroborated by other authors) considers this species as strictly European; though M. Temminck speaks of it as a visitor to Egypt and the Barbary coast.

Habits, &c.—The ardent temperament of the Partridge has been the theme of many writers on natural history from Pliny downwards; and the parental affection of the female for her young seems to be not less strong than the sexual ardour of the male. The rough nest, which is placed on the ground in corn-fields, meadows, &c., contains from twelve to eighteen or even twenty eggs of a greenish ash-colour; and the hen sits so close, that her head not unfrequently falls before the scythe of the mower, as represented in one of Bewick's admirable cuts. To relate all the anecdotes of the maternal affection of this bird would be endless—and indeed the male watches over the young with paternal care: one or two must suffice. Pennant records a strong instance:—A partridge followed by a large covey of very young birds was surprised by a violent shower of rain. 'She collected them under her,' says Pennant, 'and to secure them further, spread her wings to prevent every injury. In vain! The storm encreased, yet she would not quit her charge; she preferred death, and we found her lifeless (with all the little brood) with distended wings, retaining her attempt to preserve them even to the very article of death.' Mr. Selby relates that a person engaged in a field not far from his residence had his attention arrested by some objects on the ground, which, upon approaching, he found to be a male and female partridge, engaged in battle with a carrion crow; so absorbed were they in the issue of the contest, that they actually held the crow, till it was seized and taken from them by the spectator of the scene. Upon search, the very lately hatched young were found concealed among the grass, and the crow had been doubtless attacked by the parents during his attempt to carry off some of their offspring. The wiles and stratagems put in practice by the hen to draw the intruder from the place where her affrighted young have taken refuge are wonderful: she will limp about as if lame of a leg or wing, and so induce one unaccustomed to her deceptions to follow her from the brood, to which she flies back by a circuitous route. White saw a hen partridge come out of a ditch, and run along shivering with her wings, and crying out as if wounded and unable to get from him. While the dam acted this distress, the boy who attended White saw her brood, which was small and unable to fly, run to an old fox-earth for shelter. Markwick, too, observes that it is not uncommon to see an old partridge feign itself wounded and run along on the ground fluttering and crying before either dog or man, to draw them away from its helpless unfledged young ones. 'I have seen it often,' says Markwick, 'and once in particular I saw a remarkable instance of the old bird's solicitude to save its brood. As I was hunting a young pointer, the dog ran in on a brood of very small partridges; the old bird cried, fluttered, and ran tumbling along just before the dog's nose, till she had drawn him to a considerable distance, when she took wing and flew still farther off, but not out of the field: on this the dog returned to me, near which place the young ones lay concealed in the grass, which the old bird no sooner perceived than she flew back again to us, settled just before the dog's nose again, and by rolling and tumbling about, drew off his attention from her young, and thus preserved her brood a second time. I have also seen, when a kite has been hovering over a covey of young partridges, the old birds fly up at the bird of prey, screaming and fighting with all their might to preserve their brood.'

Aristotle describes his *Perdix* (see post) as tumbling about to draw intruders from her nest, and fixing their attention till the young have time to escape. (*Hist. Anim.*, ix. 8.)

The pairing time is generally about the beginning of February, but notwithstanding the ardour of these birds, the attachment soon seems to be directed to another object, if any accident happen to that first selected; at least as far as the female is concerned. White mentions a sportsman whose zeal for the increase of his game being greater than his humanity, he, after pairing time, always shot the cock bird of every couple of partridges upon his grounds, supposing that the rivalry of many males interrupted the breed: he used to say, that though he had widowed the same hen several times, yet he found she was still provided with a fresh paramour that did not take her away from her haunt.' The same delightful author states that he knew a lover of setting, an old sportsman, who had often told him that soon after harvest he had frequently taken small coveys of partridges, consisting of cock birds alone, which he pleasantly used to call old bachelors. It thus appears that the number of males much exceeds that of the females: the rivalry between the amorous combatants in the spring—and their battles are long and bloody—would seem to be the usual provision to secure the strongest males for the continuation of the species. They roost on the ground together, generally in large fields, far from hedges or coverts, probably, as White observes, to secure themselves from pole-cats and stoats. There are accidental pied or whitish varieties.

Common Partridge.

The above form has been separated from the other partridges, *Perdix Græca*, Briss., *Perdix rubra*, *Perdix petrosa*, &c., by the Prince of Musignano. The first of these (*Perdix saxatilis* of Meyer, *La Bartavelle*) is most probably the πέρδιξ (Perdix) of Aristotle. All these, which are European, as well as *Perdix Chukar* from the Himalaya mountains, have a rudimentary blunt spur on the tarsus, which, with their general plumage and red legs and bill, seem to justify the Prince's separation.

The *Greek Partridge* inhabits the Alps, the Tyrol, Switzerland, Italy, Turkey, and the Archipelago. *Perdix petrosa* (the *Barbary Partridge*) is common on that part of the African coast and in the southern portions of Europe, especially those which are washed by the Mediterranean Sea. In the mountainous parts of Spain, and in the islands of Majorca and Minorca, Sardinia, Corsica, Malta, and Sicily, it is abundant; but it is rare in France, and not known in the north of Europe. *Perdix rubra*, the common *Red-legged* or *Guernsey Partridge*, is abundant in France and Italy, rare in Switzerland, and still rarer in Germany and Holland. Mr. Gould observes that it is confined to the European continent and the islands of Guernsey and Jersey, but M. Temminck (*Manuel*, part iv.) states that it is found in Japan, where it was observed by Dr. Von Siebold and M. Bürger, identical in form and colour of plumage. It has been introduced into our preserves, and is now rather plentiful in some parts, especially in Suffolk. But we doubt whether those who have introduced it have much reason to be pleased with the importation. They persecute almost to extermination the Common Partridge (*Starna cinerea*), a much better bird, whether regard be had to the sports of the field or the pleasures of the table. They are most determined runners, and few birds are more calculated to injure the behaviour of a well-bred and well-broken pointer or setter than the Red-legged Partridge; if anything can make him puzzle, that partridge will. Though the flesh is not so juicy as that of the Common Partridge, a well fed plump young red-legged partridge, split down the back and broiled upon a good clear fire, is not bad eating. It is probably the *Perdix* of the antient Italians. Martial (xiii. 76), in allusion to the insane epicurism of the Romans, which seems to have valued price more than flavour, says

---

* The word *Pertrisen* or *Petrisen*, in use by the Welsh, is supposed to be borrowed from the Normans.

'Carior est Perdix; sic sapit illa magis.'

Francolinus. (Briss.)

Generic Character.—*Bill* small, moderate in size, convex above, and slightly curved downwards at the tip. *Nostrils* basal, lateral, partially closed by a naked over-arching membrane. *Tail* of twelve feathers, moderate, slightly rounded. *Feet* naked, four-toed, tarsi of the male armed with strong blunt spurs.

This is the genus *Pternistes* of Wagler, and *Chætopus* of Swainson.

The rudimentary spurs of the *Red-legged Partridges* become in the *Francolins* well developed.

Geographical Distribution of the Genus.—The old continent and its islands. The form occurs in Europe, Asia, and Africa. The Francolins are forest birds, perch on trees, and feed on seeds, bulbs, &c.

EUROPEAN FRANCOLIN.

The *European Francolin, Le Francolin à collier roux* of the French, *Francolino* of the Italians, *Francolinus vulgaris*, is a fine and handsome bird; and the plumage of the adult male is rich.

Mr. Gould, who has given beautiful figures of the male and female, of the natural size, in his 'Birds of Europe,' says, 'In the bird before us we trace, or fancy we can trace, one of those unions through which the splendid-coloured Pheasants of the East are united to the sober-coloured Quails and Partridges of the European continent, its form and habits connecting it with the latter, while its colouring manifests a relationship to the beautiful Oriental genus *Tragopan*. The near relationship which we fancy exists between the genera *Francolinus* and *Tragopan* consists in their general style of colouring, in their short spurs, and in the conformation of the beak. Another section of the genus *Francolinus*, peculiar to Africa, exhibits also a form differing from these in the structure of the beak, in which particular, as well as in the uses to which it is applied in obtaining food, it assimilates to the Oriental genus *Lophophorus*; still between these groups we may yet expect to find others, harmonising with each so as to form a complete amalgamation.'

We select Mr. Gould's description as being very accurate. In the male, the feathers on the top of the head are black, with a margin of yellowish brown; ear-coverts white; circle round the eyes, lower part of the cheeks, sides of the head and throat of a deep black, below which a broad chestnut collar extends round the neck; wings and back yellowish brown, each feather having a dark reddish brown centre, except those of the quills, which are barred with this colour; rump and tail-coverts white, barred with black, as are also the middle tail-feathers, the outer ones being entirely black; breast and lower parts black; sides blotched with black and white; thighs brownish, barred with black; under tail-coverts chestnut; beak black; legs reddish flesh-colour; tarsi spurred.

In the female the general ground-colour of the plumage is yellowish brown, darker on the cheeks and quill-feathers, and becoming paler on the under parts; the feathers of the back and wings are marked as in the male; the breast and under surface irregularly crossed with bark-shaped marks of dark brown; the rump and tail-coverts barred alternately with broad marks of obscure brown and narrow lines of white; under tail-coverts chestnut; beak brownish; legs reddish; tarsi unarmed. (*Birds of Europe.*)

Habits, Food, &c.—This Francolin haunts humid places, perches on trees, and feeds, like the Common Partridges (which, as Mr. Gould observes, it resembles in the form of the bill), on insects, seeds, &c., but not on bulbs, like others of the genus. M. Temminck, in the lately published part of his 'Manuel' (the fourth), mentions myrtle-berries and the tender tops of herbs among its food. Nothing particular seems to be known about its nest, &c.

Localities.—This species is widely distributed. M. Temminck, in the second part of his 'Manuel' (1820) states that it inhabits the most southern parts of Europe, Sicily, Malta, Sardinia, the kingdom of Naples, the islands of the Archipelago, and Turkey. The species is the same, he adds, throughout Asia and in the north of Africa, its haunts being marshes and prairies.

Mr. Gould says that in Europe its habitat appears to be exclusively confined to the southern regions, as Sicily, Malta, and the Neapolitan territories, but it is also found, he adds, in the north of Africa, and over the greater portion of the Asiatic continent. He had received it in collections from the Himalaya Mountains. M. Temminck, in the fourth part of his 'Manuel' (1840), remarks that it is not found in Sardinia nor in the kingdom of Naples, that it is still abundant in the humid spots between Caltagirone and Terranova, but almost entirely annihilated elsewhere. Individuals from Bengal and Persia differ in nothing, he adds, from those of Europe.

Utility to Man.—The flesh of this species is highly esteemed, particularly in India.

ASIATIC FRANCOLINS.

The *Francolinus Ponticerianus, Perdix Ponticeriana* of Latham, *Ferruginous and Grey Francolin*, appears to be confined to Asia.

This species, according to Colonel Sykes, is the *Teetur* of the Mahrattas, and is called a partridge in the Dukhun (Deccan), where it is the most common of birds, frequenting gardens and cultivated lands. The Colonel describes the irides as intense red brown, and its length, inclusive of the tail (which is three inches and six-tenths) as fourteen inches. He states that it is not met with in the Ghauts, unless in well cultivated valleys, and not at all on the mountains. It roosts on trees, in which situation the Colonel on more than one occasion, shot them during the day time; but this was a rare occurrence. (*Zool. Proc.*, 1832.)

Francolinus Ponticerianus.

Another Francolin, *Francolinus spadiceus*, measuring with the tail (which is five inches) fourteen inches and seven-tenths, is very common in the thick brushwood of the Ghauts. Colonel Sykes had both sexes alive in his possession for some time, and has no doubt that they might be successfully introduced into Europe. He describes them as excellent eating, and says that they rarely take wing or perch. The male has a harsh trisyllabic call, *Koh-kut-tee*, whence the Mahrattan name (*Kokatree*). The female in confinement uttered little notes like the twittering of a chicken. A male in Colonel Sykes's collection had three large spurs on one leg and two on the other. (*Zool. Proc.*, 1832.)

African Francolins.

Africa seems to be the locality of several species of Francolin. Dr. Smith has figured four in his useful and beautiful work* now in course of publication.

We select *Francolinus pileatus* as an example.

Description.—Upper surface of the head rusty grey, clouded with brown; back and sides of the neck, together with the interscapulars, intermediate between brownish orange and reddish brown, the feathers of the former broadly margined with white, and those of the latter marked each with a broad white stripe along the centre; in some the stripe is divided longitudinally by a narrow black line, in others it is margined on each side by a brownish stripe; back and upper tail-coverts yellowish grey; the former faintly clouded with brown, the latter delicately mottled with very fine transverse lines of the same colour; shoulders hair brown, several of the feathers broadly edged with reddish brown, and all marked with a white stripe in the course of the shafts; primary quill-coverts and primary and secondary quill-feathers chocolate brown, with yellowish white shafts; the outer vanes of the primaries towards their bases margined with pale sienna yellow, or light reddish brown, and those of the secondaries, throughout their whole length, with white; over each eye a white stripe, which terminates at the nape of the neck, and beneath the eye another, which ends before the ear-coverts; these stripes in front of the eye are separated from each other by a dark-brown blotch; chin, throat, and cheeks white, the two latter delicately spotted with pale reddish orange; the breast and belly cream-yellow, the former marked with large fan-shaped, dark reddish-brown spots, and the latter closely barred with delicate undulated brown lines; vent and under tail-coverts pale ochry yellow, sparingly barred with zig-zag brown lines; two central tail-feathers light reddish brown, closely mottled with delicate waved brown bars; the remaining feathers dark umber-brown, except the outer vanes towards the quills, which are reddish brown, freckled with indistinct lines of a darker shade; bill dark horn-coloured; eyes reddish brown; tarsi and toes pale Dutch orange; claws and spurs pale horn-colour. Length, from point of bill to tip of tail, thirteen inches six lines. (Smith.)

The *female* nearly resembles the *male* whose plumage is above described, but her tarsi are unarmed.

Francolinus pileatus. (Smith.)

Locality, Habits, Food, &c.—The expedition under the direction of Dr. Smith saw the first specimens of this handsome Francolin on the banks of the Marikwa river, which flows in a north-easterly direction from Kurichane. 'It showed,' says Dr. Smith, 'but little disposition to resort to the jungle, though when disturbed in more open localities, which it by choice frequents while feeding, it, like *Francolinus Natalensis*, seeks concealment in the bosom of the thickets. Early in the morning specimens were observed in moderate abundance upon the open grassy plots which occurred intersecting the wooded regions that skirted both sides of the stream, and there they appeared to find their food in plenty, which was found to consist of small bulbous roots, seeds, insects, &c. To the same localities these birds were also observed to resort towards evening; but at that period they were less readily discovered, owing to their being commonly more silent at that time. During the middle of the day they were rarely observed, and from what was ascertained there were grounds for believing they repose while the sun is warm, and that while enjoying rest they are generally perched upon dwarf trees or shrubs, no doubt to be the more secure from the teeth of the numerous predatory quadrupeds which are constantly traversing the woods in quest of prey.'

Francolinus Swainsonii of the same author, with its naked throat, wrinkled space round the eye, and more sombre plumage, seems to be a step towards some other rasorial forms, and to differ so much from its congeners as almost, if not quite, to justify separation.

Coturnix. (Briss.)

We now return to the Partridge-like (Starna) plumage and bearing and the spurless legs of the smaller *Perdices*, vernacularly known as *Quails*.

Generic Character.—Bill naked at the base, slender, convex above, curved towards the end; no red eye-brows. *Tarsus* spurless. *Tail* short. *Wings* rounded. First quill of equal length with the rest.

Geographical Distribution of the genus.—The Old World and Australia only.

European Quail.

Example, *Coturnix dactylisonans*, Mayer (*Tetrao Coturnix*, Linn.; *Perdix Coturnix*, Latham.).

This well known bird, a description of which would be superfluous, seems to be the Ortyx (ὄρτυξ) of Aristotle, who mentions the bird repeatedly in such terms as to its habits and migration as to leave little or no doubt on the point; and the *Coturnix* of the antient Italians. It is the *Quaglia* of the modern Italians; *Caille* of the French; *Wachtel* of the Germans; *Sofliar* and *Rhinc* of the antient Britons; and *Quail* of the modern British; *Lohah* and *Lowa* of the Mahrattas.

Geographical Distribution.—The Quail is very widely distributed. 'No individual of the Gallinaceous order,' says Mr. Gould, 'enjoys so wide a range in the Old World as the *Common Quail;* it is abundant in North Africa, most parts of India, and, if we mistake not, China; while the whole of the southern portions of Siberia, and every country in Europe except those approximating to the polar circle, are visited by it annually, or adopted for a permanent abode. A considerable number are stationary in the southern portions of Europe, such as Italy, Spain, and Portugal, but their numbers are greatly increased in the spring by an accession of visitors which emigrate from the parched plains of Africa in search of more abundant supplies of food and a congenial breeding-place. So vast and countless are the flocks which often pass over to the islands and European shores of the Mediterranean, that a mode of wholesale slaughter is usually put in practice against them, a circumstance which no doubt tends to limit their inordinate increase.'

These migrations have been noticed by the earliest writers on natural history. Thus Aristotle speaks of their autumnal departure in the months Boedromion and Maimacterion (*Hist. An.*, viii. 12). Belon speaks of finding them on the shores of the Mediterranean in spring and autumn at their arrival and departure, and of their flying on board his vessel for repose. Once in his passage from Rhodes to Alexandria he ate of some that had been taken with corn unchanged in their crops. Hasselquist states that an amazing number of these birds come to Egypt in the month of March, when the wheat ripens there. 'They conceal themselves,' says he, 'in the corn, but the Egyptians know extremely well that there are thieves in their grounds; and when they imagine a field to be full of them, they spread a net over the corn and surround the field, at the same time making a noise by which the birds are frightened, and endeavouring to rise, are caught in the nets in great numbers, and make a most delicate and agreeable dish.'

---

* 'Illustrations of the Zoology of South Africa.'

Dr. Von Siebold and M. Bürger mention a variety of this species as an inhabitant of Japan. M. Temminck states (*Manuel*, 4th part) that those individuals which he had received from the last-named locality differed scarcely at all from those of Europe and Africa. He observes that the species varies in size and stature.

In this country the bird is not very abundant; and the supply for the London market comes principally from France. It arrives here in spring, generally early in May, and departs in October. The males come first, betray themselves by their three repeated whistle, and are frequently lured within reach of the fowler by the imitation of the female's note on a quail-pipe; sometimes by the voice, but the performer must be a perfect mimic.

Habits, Food, Reproduction.—The ardent and pugnacious nature of these birds was taken advantage of by the ancients, and quail-fighting was a favourite amusement of the Greeks and Romans, as it still is of the Chinese. Their food consists of grain and seeds, insects, and slugs or worms. They are fattened for the table on hemp-seed principally. Pennant is too general when he says that the ancients *never* ate these birds, supposing them to have been unwholesome, as they were said to feed on hellebore. *Pliny* indeed (*Nat. Hist.*, x. xxiii.) says they were not eaten on account of their feeding on poisonous seeds; and also because they were subject to the epilepsy, or falling sickness, but this vulgar error did not, we suspect, banish so delicious a bird from the tables of the better informed. (See *Athenæus*, *Deipn.*, ix. xlvi.; ibid. xlviii.; xi. xxiv.)

The *Quail* is polygamous; and the nest of the female, if nest it may be called—for it is little more than a hole scratched in the ground, generally in some field of green wheat—contains, in this country, from six to twelve or fourteen bluish dusky-green or olive-green eggs. On the Continent, as many as eighteen or twenty have been found; but here six or eight is the usual number of a *bevy*, as the brood is called: *covey* is the term applied to a family of partridges.

Quails are noted by Hasselquist as having been seen by him in Galilee. The *Quail of the Israelites* (*Tetrao Israelitarum*, Hasselq.) was considered by him to be a new species of *Tetrao*: he found it at Jordan, and in the wilderness near the mountains of Arabia Petræa. Hasselquist describes it, in a letter to Linnæus, as much resembling the red partridge, but not larger than a turtle dove. 'I expect,' says Hasselquist, 'in a few days, to get a score of them alive, which were promised me by a person at Jerusalem, whither the Arabians carry many thousands to sell at Whitsuntide. If natural history can give any information in the interpretation of the Bible, this bird is certainly the same with the Quails of the Israelites, and they alone would deserve a journey to Jordan; for my part, I was so pleased with this discovery as to forget myself, and almost lost my life before I could get one into my possession.' In his list of birds seen by him in the Holy Land, the *Tetrao Israelitarum* is again mentioned as having been met with in the deserts near the Dead Sea. Linnæus, to whom Hasselquist's specimens as well as his observations were in all probability communicated, makes his *Tetrao Israelitarum* a synonym of his own *Tetrao Coturnix*, the *Common Quail*, and in this he is followed by Gmelin and others generally. Col. Sykes, who has devoted much attention to the Quails and *Hemipodii*, remarks that the fact of *Coturnix dactylisonans* being the only species of quail that migrates in multitudes is another reason for connecting it with the bird of Scripture, and indeed he pronounces it to be the identical species on which the Israelites fed. This is perhaps not the place to discuss such subjects, but it may be necessary to remind the reader that Rudbeck asserted that the living food which 'came up and covered the camp' (*Exod.*, xvi. 13) was the *Flying-Fish*. We dismiss this at once. Ludolph, who thought that the animal was a locust, is, at first sight, more worthy of attention; but the word שאר (*sheer*, 'flesh') (*Psalm* lxxviii. 27) could hardly have been applied to locusts. Then, according to good authorities (Bochart; Harris), the Hebrew word in *Exodus* is שלו (*selav*, Arabic *selwa* or *salwai*, a quail), and the Septuagint and Vulgate both lead to the conclusion that it was certainly a bird, and almost certainly a quail. See further Scheuchzer, *Physica Sacra* (vol. i., p. 175), where the Hebrew is translated upon both sides of the page 'coturnix,' as it is at p. 180; but the plate referred to, tab. clvi., represents the Israelites collecting locusts, and beneath the plate is printed 'Exod. xvi. 13, Selavim. Locustæ.' In the very next plate however, tab. clvii., representing many birds, we have the same chapter and verse quoted, with the following translation: 'Selavim, Coturnices, aliaque.' Fig. 2 of that plate is no bad representation of a quail. There can be little doubt that *Quails* formed the seasonable supply; and, if this be admitted, we have, as Col. Sykes observes, proof of the perpetuation of an instinct (migration) through upwards of 3300 years, the fact recorded having occurred 1491 years before Christ.

The song of Quails is noticed by Athenæus (*Deipn.*, ix. xlviii. p. 392). Bechstein, among the attractive qualities of the species, reckons, besides the beauty of its form and plumage, the *song of the bird* as no slight recommendation to the amateur. He states that in the breeding season the song of the male commences by softly repeating tones resembling '*werra, werra*,' followed by '*pickwerwick*' uttered in a bold tone, with the neck raised, the eyes shut, and the head inclined on one side. Those that repeat the last syllables ten or twelve times consecutively are the most esteemed. The song of the *female* only consists of '*werra, werra*,' '*pupu, pupu*,' the two last syllables being those by which the male and the female attract each other's attention. The angry cry generally resembles, according to Bechstein, the word '*guillah*;' but at other times it is only a purring murmur. (*Cage Birds*.)

ASIATIC QUAILS.

Col. Sykes, in his valuable paper 'On the Quails and Hemipodii of India' (*Zool. Trans.*, vol. ii.), in which he states that he found the tongue and the cæca of birds to be of considerable importance in indicating affinities or dissimilarities between genera, notices *Coturnix dactylisonans*, *textilis*, *Erythrorhyncha*, *Argoondah*, and *Pentah*. Of these we select *Coturnix Argoondah*, the *Rock Quail* of Dukhun (Deccan).

Col. Sykes remarks that there are so many trifling variations in the markings of the plumage of the upper surface of this bird, that it is difficult to fix upon the exact type. 'The male,' he says, 'is readily distinguished by the numerous transverse narrow black bars upon the breast; but the young males and the females want these bars, and vary so much in the markings on the back, that with those disposed to manufacture species from plumage alone, the eleven specimens before me from Dukhun would furnish at least four new species.' The Colonel however gives an elaborate and accurate description of the sexes (which scarcely differ in size) in a mature state, to which we refer the reader.

Coturnix Argoondah. (Sykes.)

Food, Habits, &c.—Grass-seeds only were found in the stomachs of Col. Sykes's specimens. He states that they do not frequent cultivated lands, but are found all over the Dukhun on the general level of the country, amidst rocks and low bushes, and that they rise in coveys of from ten to twenty or more, from under the feet, with startling suddenness and bustle, so that the young sportsman is perplexed in selecting his bird. They are gregarious, and, as Col. Sykes states, polygamous; for he never saw them solitary or in

The instrument is furnished with a stop or strap, so that after the distance is measured, the perambulator may be conveyed without the index being altered.

Unlike the pedometer, it requires no regulating, and the only risk of its giving the distance incorrectly, if well constructed, is in passing over rugged and uneven roads, which will of course cause the index to show more than the true distance. In general however, for short distances, this error is very trifling.

When about to commence a measurement, the wheel should be turned round until the first-mentioned index points to 220 on the circle of yards. Some are provided with a click and racket, by which this may done with much less trouble than by the wheel.

There are other instruments for the same or similar purposes, bearing different names, as *waywiser* and *odometer;* but the construction of all of them is very similar.

Waywiser is the name generally given to that form of the instrument which is applied to a carriage, in which, by a slight adaptation to one of the wheels of the carriage, the instrument is made to register the number of turns of such wheel, in the same manner as the perambulator.

PERAME'LES. [Bandicoot; Marsupialia, vol. xiv., p. 437; and see further Professor Owen's paper 'On the Osteology of the Marsupialia' (*Zool. Proc.*, 1838).]

PERCEPTION is that power or act of the mind by which it holds communication with the external world. It is distinguished from *conception* by the circumstance that its objects are in every instance supposed to have an actual existence. We may conceive things that have no reality, but we are never said to perceive such things. Perception differs from *consciousness* in that it takes cognisance only of objects without the mind. We *perceive* a man, a horse, a tree; when we think or feel, we are *conscious* of our thoughts and emotions. It is further supposed in perception that the objects of it are present. We can *remember* former objects of perception, but we do not perceive them again until they are once more present. Besides the sense which has been explained, the term perception is sometimes analogically employed in common speech in reference to truths the evidence of which is certain. Thus we may perceive the truth of a mathematical proposition. But Mr. Hume is perhaps the only writer of eminence who designedly applies the word in a metaphysical disquisition with a meaning different from that which has been here assigned to it. By him it is applied indiscriminately to all the operations and states of the mind; passions being designated perceptions, and the acts of memory and imagination converted into so many acts of perception. Such latitude of phraseology confounds under one general name things essentially distinct, and tends to introduce vagueness and inaccuracy into a department of philosophical investigation where definiteness and precision are peculiarly indispensable.

The distinction between things *perceived* (*αἰσθητά*) and things *conceived* (*νοητά*) was familiar to the Greek philosophers and to their Latin expositors, of whom Cicero expresses the former class of things by the phrases 'quæ sunt,' 'quæ cerni tangive possunt;' and the latter by the phrases 'quæ tangi demonstrarive non possunt, cerni tamen animo atque intelligi possunt,' and gives examples of each. (*Top.*, v.)

The perceptive faculty is exercised through the instrumentality of the senses. We see by means of the eye, and hear by means of the ear, and so in reference to the other senses. An individual in whom these organs are wanting or defective, will either not perceive at all, or perceive imperfectly. In order to perception it is requisite that an impression should be made on the organ of sense, either by the direct application of the object, or through some medium that communicates with the object and the organ. Thus an immediate application is necessary with regard to the senses of taste and touch; but only an intermediate one with regard to those of sight, hearing, and smell. The impression made on the organs of sense affects the nerves, and is by them conveyed to the brain. The necessity of this communication is ascertained by observation. If the nerve appropriated to any organ be cut or tied hard, no perception takes place; and the same result is noticed in certain disordered conditions of the brain, even though the organs of sense and the nerves perform their respective functions. When however the conditions that have been specified are complied with, perception ensues.

Various theories have been formed to explain the functions of the nerves and brain in connection with perception. It was imagined by the antients that the nervous fibres are tubular, and filled with a subtile vapour named animal spirits; that the brain is a gland by which this æthereal fluid is secreted; and that by means of it the nerves perform their office. (Reid, *Essay* ii., ch. 3.) Des Cartes, who adopted this hypothesis, has described with great minuteness how all mental operations and movements are accomplished through the agency referred to. Dr. Briggs, Newton's instructor in anatomy, was the first who proposed a new doctrine on this point. He maintained that the nerves operate by vibrations, like musical chords, and thus conduct impressions to the brain. Newton himself (*Opt.*, qu. [illegible]) appears to have been inclined to a notion of this kind and the suggestions relating to it thrown out by him as a query were afterwards amplified and defended by Hartley. The latter supposed that 'external objects impressed on the senses occasion, first in the nerves on which they are impressed and then in the brain, vibrations of the small, and, as one may say, infinitesimal medullary particles;' and that these vibrations are excited, propagated, and kept up partly by the ether, that is, by a very subtile elastic fluid, partly by the uniformity, continuity, softness, and active powers of the medullary substance of the brain, spinal marrow, and nerves.' (*Observations on Man*, part i., prop. 4.) Both Des Cartes and Hartley believed that by the action of the nerves in the manner described by them, images of external objects were formed in the brain.

It is scarcely necessary to remark concerning these hypotheses that they are totally destitute of foundation. A sound theory must assign real and not imaginary causes for the phenomena which it professes to explain; and such causes must have a manifest competency to the effects ascribed to them. But the hypotheses in question entirely want both of these essentials. Who can prove the existence of the animal spirits of Des Cartes, or the vibrations of Hartley; or, granting their existence, who can show any correspondence between them and the formation of images in the brain? All we can affirm with certainty respecting the means of perception is, that, under certain circumstances, that is, when an impression is made on the bodily organs and communicated by the nerves to the brain, perception takes place. The impressions so communicated are the occasions of the mind perceiving, but we can assign no reason why it should do so under these circumstances invariably, and not under any other, further than that such is the constitution of our nature.

If the act of perception be examined, it will be found that we obtain by it a certain amount of information respecting the object perceived. We discover that it has particular qualities, as for example, that it is extended, that it has figure, that it is hard or soft, rough or smooth, &c. The notion thus formed may vary in respect of distinctness in all possible degrees. In the light of twilight a body is discerned more obscurely than in the full light of noon day, and more obscurely still in proportion as the darkness deepens. The notion we get of an object by perception is accompanied by an irresistible and immediate conviction of its real existence. An object may indeed be perceived so indistinctly as to leave us in doubt whether it be real or not. If it be very distant, or involved in darkness, this may happen. But when it is plainly perceived, there is, along with the perception, a perfect conviction of its reality. We can no more doubt of its existence than we can of our own. And this conviction is immediate. It is not the result of a process of reasoning founded on our perceptions, but inseparably connected with them, and as instantaneous as the assent rendered to axiomatic truths. It may be also remarked that the belief in the existence of the objects of perception is not more immediate and deeply rooted than is the belief that they exist externally to us. They do not seem to have their place in the mind itself, but to exist independently of it altogether. These statements accord with the universal experience of mankind, and may be verified by all who choose to bestow the slightest attention on the intimations of consciousness.

It would be a tedious as well as a useless task to dwell minutely on the numerous theories that have been framed of perception. In certain important particulars nearly all of them coincide; while in others, equally if not more important, they are for the most part at variance.

Democritus taught that perception was the result of the impressions made on the organs of sense by images (εἴδωλα), which constantly emanated from bodies, and varied according to the conformation of their originals. (*Plut., Phys. Phil.*, l. iv., ch. 8, &c.)

Plato, in the seventh book of his 'Republic' (ad init.) illustrates the manner in which we perceive objects, by the figure of a cave, in which men lie bound, so that they can turn their eyes only to one part of it, where rays from a distant light stream in, and shadows of bodies, supposed to pass between them and the light, are beheld, the bodies themselves being invisible. He thus conceived that we perceive only the shadows of things, and not things themselves.

This opinion of Plato was substantially the same with that of his scholar Aristotle, and of the Peripatetics generally. Aristotle (*De An.*, l. iii., c. 2, 3) taught that as the senses cannot receive material objects themselves, they receive their images. These images are the only objects of perception in the mind. As impressed upon the senses, they are termed sensible species; more spiritualised, they become objects of memory and imagination, and are termed phantasms; still further refined, so as to be objects of science, they are named intelligible species.

The theory of Epicurus was little other than a modification of that of Aristotle. He supposed that bodies are continually casting off from their surfaces slender films or species of such subtlety that they easily penetrate by the senses to the brain. (Lucret., l. iv. v. 34, 46, &c.)

Locke employs an illustration of the manner of perception that appears to have been borrowed from that of Plato—'Methinks,' he says, 'the understanding is not much unlike a closet wholly shut from light, with only some little opening left to let in external visible resemblances, or ideas of things without. Would the pictures coming into a dark room but stay there, and lie so orderly as to be found upon occasion, it would very much resemble the understanding of a man in reference to all objects of sight and the ideas of them.'

The similitude of Locke, or rather of Plato, may be applied to all the systems of perception that have ever been formed, by merely substituting ideas, and, in the case of Hume, impressions, for what were anciently denominated species and phantasms. All these theories agree in maintaining that images are the only immediate objects of perception to the mind. Hume, Berkeley, and others indeed hold that these are the exclusive objects; but the common hypothesis admits the existence of things of which these are but the representatives, and which we mediately discern. It may be sufficient to remark concerning these opinions, that they are diametrically opposed to the testimony of our own consciousness. Instead of informing us that images alone are the direct objects of our perception, consciousness intimates nothing respecting images at all. Unless its representations are altogether deceptive, it is not things within the mind, but things external to it, that we perceive; not images of objects, but the very objects themselves. This is testimony to which we yield instinctive assurance. It is too cogent and unquestionable to be set aside by reasoning of any kind, far less by reasoning based upon certain imagined relations subsisting between matter and spirit which we are incapable of apprehending; and the application to mind of laws which apply solely to the objects of physical investigation.

One observation, intentionally deferred, remains still to be made respecting perception, namely, that it is greatly modified by habit and by the cultivation and development of the other powers. Thus the perceptions of a man and those of a child, both contemplating a piece of complex machinery, the one being aware of its principles and arrangements, the other completely ignorant of them, must in some respects considerably differ. In like manner the perceptions of a blind man, by means of those organs of sense which are unimpaired, are distinguished in many particulars from those of the individual who has never been without the faculty of vision. Numerous instances of a similar kind might easily be specified. A full account of acquired perceptions, such as those alluded to, is still a desideratum in this department of philosophical inquiry.

PERCH or **POLE**. This measure, though now mostly used as a square measure (a perch usually meaning a square perch, or a square of a perch in length and breadth), was originally a measure of length, arising out of the custom of measuring small portions of land by a staff or pole. The word *pertica*, from which it comes, means a wooden staff. But the pole with which land was measured not only differed very much in different countries, but in different parts of the same country. Ducange and his editors find records of the use, in different parts of England and France, of perches of 7½, 10 (the oldest English), 12, 15, 16, 18, 20, 21, 22, 25, and 27 feet. Here is but another instance (as in MILE and LEAGUE) of the tendency of measures to lengthen. Forty perches (quarentena), under the name of forty-long or furlong, became a common measure of length; and a piece of land forty perches long and one deep, was called *perticata*. (Spelman, cited by Ducange.) Thus the perch and furlong, though afterwards received into the system of measures which ends with the mile, originally formed no part of it whatever. (MILE.*)

By an early statute, entitled 'Compositio Ulnarum et Perticarum,' the perch was fixed at 16½ feet, or five yards and a half; and four perticatæ (though that word is not used) were defined as an acre.

A perch is the quarter of a chain, and a square perch contains 30¼ square yards.

PERCHE, LE, a province of France, united, before the Revolution, with Maine, into one military government. It was bounded on the north by Normandie, on the north-east by the Ile de France, on the east and south by Orléanais, and on the west by Maine. It was subdivided into Le Grand Perche, or Le Haut Perche (Great or Upper Perche), of which Mortagne was the capital; Le Perche Gouet, or Le Bas (Lower) Perche, of which Montmirail was the capital; Les Terres Françaises, of which Tour-Grise-de Verneuil was the capital; and Les Terres Demandées, or Thimerais, of which Châteauneuf-en-Thimerais was the chief town. Perche is now comprehended in the departments of Orne, Sarthe, and Eure et Loir.

Le Perche was under the government of its own counts from the year 940; but the original county was not equal in extent to the province of later times. Having fallen to the crown, this county was given with that of Alençon to Pierre, one of the younger sons of St. Louis (A.D. 1269); but these counties having on his death reverted to the crown, they were again bestowed on Charles de Valois, brother of Philippe le Bel (A.D. 1293), in whose family they long continued. In 1361 they were separated, Perche going to a younger branch of the family; but in 1404 they were again united.

In the reign of François I. the county was, on the death of the last male heir, seized by the crown, but the justice of the claim was for awhile disputed. During the dispute the widow of the late count was allowed to possess the county, but it was afterwards annexed to the crown domains.

PERCIDÆ, or *Percoïdes* of Cuvier, a family of Acanthopterygious fishes, of which the common perch may be regarded as the type, that is to say, the fishes of this great group, which might perhaps to be regarded as an order rather than a family, all more or less approach the common perch in general form; they have the body covered with scales whose outer surface is more or less rough, and the free margins of which are denticulated; the operculum and preoperculum are variously armed with spines and denticulated at the outer margin; they not only have teeth in both jaws, but the vomer and palatine bones are also furnished with them; the number of rays in the branchiostegous membrane varies from five to seven; they never fall short of the lower nor exceed the higher number. The flesh of these fishes is generally well flavoured and wholesome. They inhabit both salt and fresh water.

The first division of the Percidæ, according to Cuvier, comprises all those species which have the ventral fins placed under the pectorals, five soft rays to the ventral fins, seven branchiostegous rays, and two dorsal fins. This section includes the following genera:—

1. *Perca* proper, in which the preoperculum is denticulated; the operculum is produced behind into a flattened spine; the infra-orbitals are obscurely denticulated, and the tongue is smooth. Example, the common perch (*Perca fluviatilis* of Linnæus). (Yarrell's *British Fishes*.) Closely allied to this is the *P. Italica* of Cuvier and Valenciennes, a species found in tolerable abundance in some parts of Italy; it differs from the *Perca fluviatilis* in being of a shorter and deeper form, and is destitute of the black bands. Several true perches are found in North America; species have also been discovered in Java and New Zealand; it is highly probable therefore, from the extensive geographical range of the perches proper thus exhibited, that very many species still remain to be discovered.

---

* In this article (p. 213) 'perticatæ' is erroneously written for 'pertica.'

keeper would, we doubt not, soon have a young brood to show, and that once obtained, he would not be long before he would be able to turn out these graceful birds, whose habits appear to be similar to those of the Quails and some of the Partridges.

Hemipodius. (Temm.)

Generic Character.—*Bill* moderate, slender, straight, very much compressed, curved towards the point; *nostrils* basal, lateral, linear, slit longitudinally down to about the middle of the bill, and partially closed by a naked membrane. *Tarsus* long; only three toes, all of which are directed forwards and entirely divided. *Tail-feathers* weak, hidden by the upper coverts. *Wings* moderate; first *quill* longest.

This is the genus *Turnix*, Bonn.; *Tridactylus*, Lacép.; and *Ortygis*, Ill.

Geographical Distribution and Habits of the Genus.—Europe, Asia, Africa, Australia, and Oceania.

Mr. Swainson makes the genus *Ortygis* the third of his family *Tetraonidæ*, and places it between *Odontophorus* and *Tetrao*. Mr. G. R. Gray elevates the form into a subfamily, under the name of *Turnicinæ*, the first of his family *Tinamidæ*, the second and only other subfamily being *Tinaminæ*. The *Tinamidæ* are followed by the *Struthionidæ* in his arrangement. Colonel Sykes, in his paper *On the Quails and Hemipodii of India*, speaking of *Hemipodius pugnax*, says that its muscular stomach and proportionally long intestines, compared with *Otis*, would prevent its being placed in that genus; but its cursorial habits and the form of its bill would justify its displacement from the *Tetraonidæ*, and it might come in after *Otis* in *Struthionidæ*. The food of the genus consists of insects and seeds, and the birds generally frequent high herbage, in which they run with great speed. We proceed to give Asiatic and African examples of this genus.

Asiatic.

Colonel Sykes, in his paper above alluded to, describes three species—*Hem. pugnax*, *H. Taigoor*, and *H. Dussumieri*. In the stomach of the first he found the remains of black ants, minute coleopterous insects, and grass-seeds; the flesh was in brown and white layers, and the Colonel states that its pugnacious qualities are quite unknown in Dukhun, and even in Java. They were frequently in pairs, but mostly solitary, haunting cultivated lands, especially chillee fields (*capsicum annuum*). Their flight he describes as lazy and short, nor are they readily put on the wing. He adds that the Zoological Society has a specimen from Madras, and that it would appear therefore to have an extended geographical range over the Eastern islands and India. We shall presently notice *H. Taigoor*. Of *H. Dussumieri*, the *Button Quail* of European sportsmen in India, he says that it affects short thick grass and fields of pulse of *Dolichos biflorus*, *Phaseolus Max.*, and *Ervum Lens*. He never found the bird otherwise than solitary, and says that it is so difficult to flush, that it not unfrequently rises from beneath the feet; and when on the wing, its flight is so abrupt, angular, and short, that it is generally down before the gun is well up to the shoulder.

Turnix Taigoor. (Sykes.)

Example, *Hemipodius Taigoor.*

Description.—Chestnut above; feathers margined with straw colour, and with undulated bands of black; wing coverts straw-colour banded with black; quills brown, chin and throat white, breast banded with black and white, belly and vent dilute ferruginous, irides pale yellow, bill blackish. Length of the body four inches eight-tenths, of the tail one inch seven-tenths. (Sykes.)

Colonel Sykes was at first disposed to regard this species as *H. pugnax* in an immature state; but subsequent observations induce him to consider it as distinct. The measurements correspond closely with those of *H. pugnax*, but it is on the whole less robust.

In the species of *Turnix*, or *Hemipodius*, described by Colonel Sykes, the sexes do not appear to differ in plumage.

African.

Example, *Hemipodius Lepurana.* (Smith.)

Description: Colour. (*Male.*)—Above, the ground-colour is intermediate between pale rufous and light chestnut: on the upper surface of the head the feathers are indistinctly barred with brown; on the neck, back, and shoulders nearest to the body, they are crossed by numerous slender black-brown bars or irregular crescents, and some of the shoulder-coverts are besides delicately margined with white. The eyebrows, sides of the head, and a stripe between the base of the bill and nape of the neck rusty white, the feathers of the two first finely tipped with brown. The inner vanes of the secondary quill coverts pale rufous; the outer vanes straw yellow inclined to white, and each of the latter is crossed obliquely near its point by a well-defined brown bar, the inner extremity of which terminates in an acute point. Primary quill coverts dark brown; the primary and secondary quill feathers greyish brown, the outer vanes of the former finely edged with a pale buff colour, those of the latter broadly edged with cream yellow, and partially barred with the same colour. Tail pale rufous, and crossed by numerous delicate waved brown lines. Chin and throat dull white; the middle of the breast pale Dutch orange, with a few minute brown dots; sides of the breast and belly white, with a yellowish tinge, each feather with an arrow-shaped brown spot near its point; centre of the belly and the thighs white; vent and under tail-coverts very pale buff orange; bill and legs pale lilac; eyes [illegible] reddish-yellow.

Form, &c. typical; bill moderately long and slender; form approaching that of the smaller Rails (*Porzana*, Vieill.); tail rather elongated, graduated, and pointed; wings, when folded, reach nearly to the commencement of the last half of the tail; the first, second, and third quill feathers longest and nearly of equal length; the tertials slightly shorter than the longest quill feathers; tarsi [illegible] slender, in front coated with two rows of scales, and behind with one row; toes short; claws slender and slightly curved; the thighs closely covered with feathers to the knee joint. Length, from the point of the bill to the tip of the tail, [illegible] inches.

Female.—The crown of the head sparingly sprinkled with white dots, otherwise as in the male; the back of the [illegible] is pale cinnamon-brown, the feathers edged with white; back a pale fawn colour, each feather crossed by several black bars, and each bar with a more or less distinct angular projection at the shaft of the feather both before and behind, or simply behind; secondary wing coverts pale cream-yellow, each with an oblong deep brown spot on its outer vane, and a large irregular chestnut blotch on the inner continuous with the brown spot. Primary and secondary quill feathers brown, the two outermost primaries being margined with cream-yellow, the rest of the primaries and the secondaries delicately edged with pale rufous; the tertiaries pale chestnut barred with black, and here and there variegated besides with small and irregularly shaped white spots or stripes; the middle of the breast as in the male, but the sides, instead of being marked with angular spots, have them of an ovate form, and placed longitudinally on the feathers. (Smith.)

Locality, Habits, Food, &c.—Only a very few specimens of this quail, says Dr. Smith, were obtained, and these [illegible] until after the expedition had reached the country north of Latakoo. The grassy valleys south-east of Kurrichane were the only localities in which they were discovered, and even then they appeared to be but thinly scattered, for more than a single individual was seldom found in or even near the same place. When the birds were disturbed, they seldom flew far before they alighted, upon which it would seem that they continued their retreat, for none of those flushed a second time were ever found near the situations where they had been marked down. The food consists of seeds and small insects, with which the birds swallow a considerable quantity of fine gravel.

Turnix Lepurana, female. (Smith.)

Dr. Smith remarks that in the museum of the Army Medical Department at Fort Pitt, Chatham, there are the male and female of an Indian species of *Hemipodius* very closely resembling the Dr.'s *Hemipodius Lepurana*. They differ however, he observes, in so many minor points, that he feels disposed to regard them as belonging to a distinct species. In the catalogue of the Fort Pitt collection, Dr. Smith has named this Asiatic species *Hemipodius Sykesii*, in honour of Col. Sykes, who, he justly states, has added so much to our knowledge of the zoology of India. (*Illustrations of the Zoology of South Africa.*)

Before we quit this sketch of the Partridges and Quails, we must notice two forms which particularly demand attention as leading to other types. The first of these, the *Sanguine Partridge*, *Perdix cruenta* (*Pl. Col.*, 332), appears to bear the following generic names: *Ithaginis*, Wagler, *Plectrophorus*, J. E. Gray, and *Pitiquerius*, [illegible]. It is described as a pheasant in 'Linn. Trans.,' vol. xiii., and may be considered as uniting the Partridges with the *Pheasants* and the *Polyplectrons*, like the latter of which, it has often more than one spur upon the tarsus. The plumage of this bird, which is a native of Nepaul, is brilliant, and the feathers of the head and neck are elongated.

The *Perdix Lerwa* described by Mr. Hodgson (*Zool. Proc.*, 1833) inhabits, according to that gentleman, the northern region of Nepaul, and forms by its half-plumed tarsi a sort of link between the *Partridges* and the *Grouse*, the latter of which it resembles in its habits. It is found close to the permanent snows, among rocks and low brushwood, feeding upon aromatic buds, leaves, and small insects. The plumage is black, lineated transversely with white and chestnut; the breast is brown. Mr. Hodgson remarks that the great comparative expanse of the wing, the diminution of its rounded form by the second quill feather being the longest, the increased length and strength of the tail, and the extent of the feathering of the tarsi, are very remarkable characters, which give to this species a strong [illegible].

PERDICINÆ. [PERDICIDÆ.]

PERDIX (Ornithology). [PERDICIDÆ.]

PERDIX (Conchology), De Montfort's name for the *Partridge Tun* (*Dolium Perdix* of authors). [ENTOMOSTOMATA, vol. ix., p. [illegible].]

PERDU, MOUNT. [PYRENEES.]

PEREKOP. [CRIMEA.]

PERENNIBRANCHIATA. [AMPHIUMA; AXOLOTL; PROTEUS; [illegible].]

PEREZ, ANTONIO, was the natural son of Gonzalo Perez, a distinguished writer* and statesman who had been for forty years sole secretary of state to Charles V. and Philip II. After the death of his father, whom he used to assist in his administrative duties, Antonio was appointed by Philip to succeed him in that charge. At first the confidence which his sovereign placed in him, and the favours lavished upon him seem to have been unbounded, but he soon experienced the inconstancy of royal favour. John of Austria, an illegitimate son of Charles V., elated with his victories over the revolted Moors of Granada [MORISCOES], and still more by the glorious victory of Lepanto (1571), could not rest contented with the second place in the kingdom, and nothing short of a throne would satisfy his ambition. At first he solicited his brother to grant him the kingdom of Tunis to be held as a fief of the Spanish crown. A marriage with Elizabeth of England, the sworn enemy of Spain, was also seriously contemplated, and negotiations were carried on to that effect by his secret agents. It has even been surmised that he meditated at one time to put himself at the head of the rebels of Flanders. The soul of these intrigues as well as the promoter of John's ambitious designs was his secretary, Juan de Escovedo, notwithstanding he had been appointed to that office by Philip for the express purpose of counteracting them. No sooner therefore had Escovedo arrived at court for the purpose of furthering his master's views, than Philip, who was already acquainted with the whole intrigue, decided upon his ruin; but unwilling, from motives of state, to try him by the common forms of law, he committed to Perez the execution of his wishes. Accordingly, and in compliance with Philip's orders, Perez hired some assassins, who murdered Escovedo in March, 1578. A few months after the perpetration of this crime, Philip ordered Perez to be arrested at the same time with Doña Ana de Mendoza, princess of Eboli, the supposed object of the king's affection; in all appearance to yield to the solicitations of Escovedo's relatives, and the threats of John of Austria, but in reality from other motives, which, though we may guess at them, are far from being satisfactorily known. In his *Relaciones*, published several years after the tragedy, Perez treated at length of all these events, but such was his dread of Philip that he always expresses himself in very ambiguous and enigmatic terms, and the whole transaction remains wrapped up in mystery. It has been supposed by some that Perez was imprudent enough to communicate his secret to the princess, whom he used to visit without the knowledge of his master, and to hint at the king's implication in the murder of Escovedo; by others, that Philip was an unsuccessful suitor to the princess and jealous of the intimacy of Perez with her. Be this as it may, Perez was delivered into the hands of justice, a pretended investigation was instituted into his conduct, and the result was that he was condemned to two years' imprisonment, eight years' exile from court, and a heavy fine. At first his own house was assigned as his place of confinement, Philip still continuing to employ him and to promise him his protection and favour; but that wily monarch having, it is asserted, through threats and promises, obtained from him what he most wanted, namely, all the papers that might prove his own share in the murder, Perez was by his orders removed to a prison, and soon after put to the rack, where he confessed his participation in the murder of Escovedo, but at the same time stated that he received the king's orders to that effect. Perez would undoubtedly have suffered capital punishment, had not his wife Doña Maria de Coello, assisted by his friends, procured him the means of escaping from his prison, and taking refuge in Aragon his native province. On arriving at Saragossa, Perez appealed, in virtue of the Aragonese laws, to the protection of the Justiza, and insisted upon a fair and open trial; but Philip, regardless of the authority of the Justiza, of the people's liberties, and his own oaths to maintain them, commanded the magistrates of Calatayud to seize the secretary and confine him in the royal prison. At this arbitrary violation of their constitution the people of Saragossa rose in arms, and by force released the prisoner. A third and last expedient was then tried by Philip. As Perez was known to be in correspondence with Catherine, the sister of Henri IV. of France, and a Protestant, he was accused of heresy and witchcraft, and lodged in the dungeons of the Inquisition. The patriotic Justiza protested against this new infraction of the people's privileges, and the inhabitants of Saragossa, infuriated to the last degree, invaded the palace of the Inquisition and released the prisoner, after putting to death the Marquis de Almenara, Philip's representative, and committing other excesses. No sooner did Philip hear of the revolt, than he ordered a considerable army to Aragon. The Saragossians rose in arms: a tumultuous body, headed by Don Martin de Lanuza, the Justizia, went out to meet the royal troops, but having hastily fled at their approach, the unfortunate nobleman was taken prisoner and immediately executed, the forms of liberty being thus for ever extinguished in Aragon. In the meanwhile Perez made his escape into France, where he published the narrative of his sufferings and found protection. He also visited England, and was kindly received by Elizabeth's ministers, and other illustrious men of the time, such as the Earl of Essex, Lord Southampton, Francis and Anthony Bacon, &c., with whom he maintained a correspondence in Latin. He seems even to have entertained an idea of going to Scotland, as appears from a letter of his to James VI., and another addressed to him by Thomas Parry, which are preserved in the library of the British Museum among the Cotton MSS., Caligula, E. vii. During Perez's stay in France several unsuccessful attempts were made by Philip to have him assassinated. Estoile (*Journal de Henry IV.*, vol. ii., p. 253) says that a Spaniard, named Rodrigo Mur, was executed at Paris in 1596 for attempting to murder Perez, and that when he was put to the rack, he confessed that he was sent by Idiaquez, minister of Philip II. Perez died, miserably poor, at Paris, on the 3rd November, 1616, and was buried in the monastery of the Celestins, where his tomb, bearing a Latin epitaph, was still to be seen shortly before the Revolution. Besides his *Relaciones*, which appeared for the first time at Paris in 1598, and were afterwards reprinted there in 1624, and at Geneva in 1631, 1644, and 1654, and his *Cartas y Aphorismos*, published at Paris in 1603 and in 1605, besides other subsequent editions without date, Perez is said to have written a history of Philip II., and some political works. There is also a collection of letters by him addressed to the Connetable de Montmorency, preserved in the royal library at Paris. Part of the former work was translated into French and also into Latin, with this title, *Institutiones Imperiales*, Amst., 1657.

* He [illegible]

(Watson's *Philip II.*, vol. iii.; Ferreras, *Synopsis Historial*, vol. x., part 16; Cabrera, *Historia de Felipe II.*, Mad., 1619; Vanderhammen, *Historia de Don Felipe el Prudente*, Granada, 1649; Nicolas Antonio, *Bibl. Nova*, tom. i.)

PE'RGAMOS, or PERGAMUM (Πέργαμος, Πέργαμον), the most important town in Mysia, is first mentioned in Xenophon's 'Anabasis' (vii. 8, s. 8). It was strongly fortified by nature and art, and was chosen by Lysimachus as the most secure place in his dominions for depositing his treasures. He committed the charge of them to Philetærus, a native of the small town of Teium in Pontus (Strabo, xii. 543), who remained faithful to his charge for some time; but having been injuriously treated by Arsinoe, the wife of Lysimachus, he declared himself independent about B.C. 283, and remained master of the town and a small part of the surrounding country till his death, B.C. 263. (Strabo, xii. 623.) He was succeeded by his nephew Eumenes, who increased his dominions, and even gained a victory near Sardis over Antiochus, son of Seleucus. He reigned for 22 years, and was succeeded, B.C. 241, by his cousin Attalus I., whose father was the younger brother of Philetærus. (Strabo, xii. 624.)

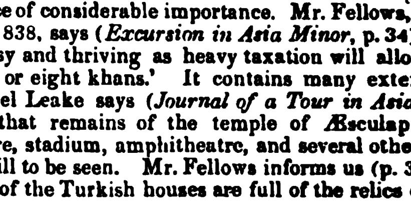
Attalus was the first of the rulers of Pergamos who received the title of king. He was a successful general, and his prudence as well as valour greatly extended the limits of his kingdom. He conquered the Galli-Græci, or Galatians, and afforded effectual assistance to the Romans in their wars against Philip of Macedon. He died at the age of 72, after a reign of 44 years, and was succeeded, B.C. 197, by his son Eumenes. (Polyb., xviii. 24; Liv., xxxiii. 21; Strabo, xiii. 624.)

Eumenes continued, like his father, a firm friend of the Romans, and in consequence of his services in their wars against Antiochus and the kings of Macedonia, he received from them all the territory conquered from Antiochus on this side of Mount Taurus. Previous to this, the territory of the kings of Pergamos did not extend beyond the country bordering on the gulfs of Adramyttium and Elæa. (Strabo, xiii. 624; Liv., xxxviii. 39.) Eumenes was a warm patron of the arts and sciences. He embellished the city with many public buildings, and founded a library, which became only second in importance to that of Alexandria. In consequence of the prohibition against exporting papyrus issued by Ptolemy, he is said to have invented parchment (Plin., *Hist. Nat.*, xiii. 21), but this material was probably known before his time. [PARCHMENT.] The library remained at Pergamos till Antonius made a present of it to Cleopatra. (Plut., *Ant.*, c. 58.) Eumenes was distinguished, according to Polybius (xxxii. 23), by many eminent qualities, and left his kingdom in a very flourishing state. He died B.C. 159, after a reign of 39* years, leaving an infant son to the care of his brother Attalus II., who administered the affairs of the kingdom with great success for 21 years. He was succeeded by Attalus III., the son of Eumenes, who died after a reign of five years, B.C. 133, leaving his property by will to the Romans, which they interpreted to mean the kingdom of Pergamus. (Liv., *Epit.*, 50; Plut., *Tib. Gracch.*, c. 14.) The kingdom however was claimed by Aristonicus, a natural son of Eumenes; but he was defeated and taken prisoner by the Romans, B.C. 129, and the kingdom became a Roman province under the name of Asia. (Strabo, xiii. 624.)

The history of the kings of Pergamos is given in an Appendix to Clinton's *Fasti Hellenici* (vol. iii., p. 400-410). Compare the article ATTALUS in this work.

Pergamus was situated north of the river Caicus (*Ak-su* or *Bakir*). The small river Selinus flowed through it. (Plin., *Hist. Nat.*, v. 33.) The citadel, which was very strongly fortified, was built on a hill of a conical shape. The town itself was very large, and possessed many public buildings, of which the most celebrated was a temple of Æsculapius, which possessed the right of asylum. (Tac., *Ann.*, iii. 63; App., *Mith.*, c. 60.) Pergamos was one of the seven churches to which St. John wrote in the book of the *Revelation* (i. 11; ii. 12). It continued to be the capital of the Roman province of Asia. Pliny (*Hist. Nat.*, v. 33) calls it by far the most celebrated town in Asia (that is, the province of Asia). The modern town, which is called Bergma, is still a place of considerable importance. Mr. Fellows, who visited it in 1838, says (*Excursion in Asia Minor*, p. 34) that 'it is as busy and thriving as heavy taxation will allow, and has seven or eight khans.' It contains many extensive ruins. Colonel Leake says (*Journal of a Tour in Asia Minor*, p. 266) that remains of the temple of Æsculapius, of the theatre, stadium, amphitheatre, and several other buildings, are still to be seen. Mr. Fellows informs us (p. 34) that the walls of the Turkish houses are full of the relics of marbles with ornaments of the richest Grecian art.

The name Pergamus signifies 'a hill' or 'elevated place,' and the word is used by Homer (*Il.*, iv. 508) to express the acropolis of Ilium. The relationship of the word Pergamus to the Greek pyrgos (πύργος) and the Teutonic *berg* is obvious. The names of the towns Berge in Thrace and Perge in Pamphylia contain the same element *berg*. Compare also Herod. vii., 43, 112.



Coin of Pergamos.

PERGE. [PAMPHYLIA.]

PERGOLE'SI, GIOVANNI-BATTISTA, was born, according to Dr. Burney—who drew his information from persons well acquainted with the composer—at Casoria, near Naples, in 1704; Mattei says, at Pergola, in 1707. Sir John Hawkins makes it 1718; though it is evident that in this instance he was not so correct as usual. But in the *Gazette Musicale*, No. 49, it is stated that the Marchese di Villarosa had (recently, we conclude) published a *Lettera Biografica* concerning this very eminent Italian musician, in which he tells us, on the authority of a baptismal register, that he was born at Jesi, in 1710. Nevertheless the presumption is in favour of the English historian, as it is possible that the registration discovered by the marquess may have been that of some other person of the same name. All agree however that Pergolesi was educated at the Neapolitan *Conservatorio dei Poveri in Giesu Cristo*, under Gaetano Greco and Durante, and that at the age of fourteen, fully per-

---

[*] Strabo (xiii. 624) says 49, but this must be a mistake. See Schweigh. 'Ad Polyb.,' xxxii. 23; and Clinton's 'Fast. Hell.,' vol. iii., p. [illegible]

cluded that melody and true taste were sacrificed to what was called learning, he was withdrawn, at his own request, from school, and immediately adopted the style of Vinci and Hasse. His first productions, among which was Metastasio's *Olimpiade*, were coldly received, both at Naples and Rome, for his new manner was not understood. But the *Prince di Stigliano*, discovering his merit, procured an engagement for him at the *Teatro Nuovo*. There his light but elegant intermezzo, *La Serva Padrona*, which afterwards made so extraordinary a sensation in Paris, was brought out in 1731.

Though the dramatic compositions of Pergolesi met with little success during his short life, his productions for the church were duly appreciated, and received with the applause they deserved. His fine mass in D, in which is the no less popular than beautiful movement, 'Gloria in excelsis!' was heard 'with general rapture,' says Burney, at Rome; where also his grand motet, 'Dixit Dominus,' and his 'Laudate, Pueri,' were equally admired. At this time he began to show decided symptoms of pulmonary disease, and removed, for change of air, to Torre del Greco, at the foot of Vesuvius. Here he composed his lovely and most pathetic 'Stabat, Mater,' a Catholic hymn; likewise the motet, 'Salve, Regina' his latest work. He died in 1737, at nearly the same period of life that bounded the earthly existence of Raffaelle, Purcell, and Mozart. 'The instant his death was known,' Dr. Burney remarks, 'all Italy manifested an eager desire to hear and possess his productions, not excepting his first and most trivial farces and *intermezzi*: and not only lovers of elegant music, and curious collectors elsewhere, but even the Neapolitans themselves, who had heard them with indifference during his life-time, were now equally solicitous to do justice to the works and memory of their deceased countryman.' (*Hist.*, v. 551.)

According to Walpole, Gray the poet first made Pergolesi's works known in England. It is certain, that he considered them as models of perfection,—a fact mentioned to Dr. Burney by Walpole, Mason, and other friends of the great British poet. Pergolesi's opera, *L'Olimpiade*, was first performed at the King's Theatre in 1742; the *Serva Padrona* in 1750. His sacred compositions were performed at the Academy of Ancient Music shortly after they reached this country, and have never since ceased to be admired by all true lovers and judges of the art.

PERIANDER. [CORINTH.]

PERI'BOLUS (Conchology), a genus of Gasteropods founded by Adanson on young cowries, the outer lips of whose shells were trenchant and not yet come to their permanent form. [CYPRÆIDÆ, vol. viii., p. 224, fig. *a*, *b*.]

PERIBOLUS. [TEMPLE.]

PERICA'RDIUM. [HEART.]

PERICARDI'TIS. [HEART, DISEASES OF.]

PERICARP is strictly the shell of a seed-vessel, varying very much in texture, as between the grape, where it is fleshy, the bean, where it is hard and dry, and the peach, where it is succulent externally and stony in the inside, but in these cases always originally the simple sides of a free carpel. In practice however the term pericarp is also applied to those seed-vessels whose sides are formed of the floral envelopes and stamens in a state of adhesion to the carpel, as in the apple, gourd, &c. When the pericarp separates into distinct layers, those layers have sometimes separate names, as in the plum, whose external skin is the *epicarp*, whose pulp or flesh is the *sarcocarp*, and whose stone is the *endocarp*, or *putamen*. In such cases the endocarp answers to the upper epidermis and parenchyma of the carpellary leaf, the sarcocarp to the mesophyllum, and the epicarp to the inferior epidermis.

PERI'CERA. [MAIIDÆ, vol. xiv., p. 291.]

PERICHÆTIUM is a name given by writers on mosses to the leaves that surround the bulbous base of the stalk or seta of the seed-vessel, or sporangium.

PE'RICLES (Περικλῆς) was son of Xanthippus, who defeated the Persians at Mycale, and of Agariste, niece of the famous Clisthenes. (Herod., vi. 131.) He was thus the representative of a noble family, and he improved the advantages of birth by those of education. He attended the teaching of Damon, who communicated political instruction in the form of music lessons; of Zeno the Eleatic; and, most especially, of the subtle and profound Anaxagoras. Plutarch's account shows that he acquired from Anaxagoras moral as well as physical truths, and that while he learned enough of astronomy to raise him above vulgar errors, the same teacher supplied him with those notions of the orderly arrangement of society which were afterwards so much the object of his public life. But all these studies had a political end, and the same activity and acuteness which led him into metaphysical inquiries, gave him the will and the power to become ruler of Athens.

In his youth, old men traced a likeness to Pisistratus, which, joined to the obvious advantages with which he would have entered public life, excited distrust, and actually seems to have retarded his appearance on the stage of public life. However, about the year 469, two years after the ostracism of Themistocles, and about the time when Aristides died, Pericles came forward in a public capacity, and before long became head of a party opposed to that of Cimon the son of Miltiades.

Plutarch accuses Pericles of taking the democratic side because Cimon headed that of the nobles. A popular war usually strengthens the hands of the executive, and is therefore unfavourable to public liberty; and the Persian war seems to have been emphatically so to Athens, as at its termination, she found herself under the guidance of a statesman who partook more of the character of the general than of the prime-minister. (Heeren's *Political Antiquities of Greece*.) Cimon's character was in itself a guarantee against aggrandisement either on his own part or others; but we may perhaps give Pericles credit for seeing the danger of so much power in less scrupulous hands than Cimon's. Be this as it may, Pericles took the popular side, and as such became the opponent of Cimon.

About the time when Cimon was prosecuted and fined (before B.C. 461), Pericles began his first attack on the aristocracy through the sides of the Areopagus; and in spite of Cimon, and of an advocate yet more powerful (the poet Æschylus), succeeded in depriving the Areopagus of its judicial power, except in certain inconsiderable cases. This triumph preceded if it did not produce the ostracism of Cimon (B.C. 461). From this time until Cimon's recal, which Mr. Thirlwall places, though doubtfully, in the year 453, we find Pericles acting as a military commander, and by his valour at Tanagra preventing that regret which Cimon's absence would otherwise undoubtedly have created. What caused him to bring about the recal of Cimon is doubtful; perhaps, as Mr. Thirlwall suggests, to strengthen himself against his most virulent opponents by conciliating the more moderate of them, such as their great leader himself.

After the death of Cimon, Thucydides took his place, and for some time stood at the head of the stationary party. He was a better rhetorician than Cimon, in fact more statesman than warrior; but the influence of Pericles was irresistible, and in 444 Thucydides was ostracised, which period we may consider as the turning point of Pericles's power, and after which it was well nigh absolute.

We are unable to trace the exact steps by which Athens rose from the situation of chief among allies to that of mistress over tributaries; but it seems pretty clear that Pericles aided in the change, and increased their contributions nearly one-third. His finishing blow to the independence of the allies was the conquest of Samos and Byzantium, a transaction belonging rather to history than biography; he secured his success by planting colonies in various places, so as to accustom the allies to look on Athens as the capital of a great empire, of which they themselves were component parts, but still possessed no independent existence.

From this time till the beginning of the Peloponnesian war, Pericles appears engaged in peaceful pursuits. He constructed a third wall from Athens to the harbour of the Piræus. He covered the Acropolis with magnificent buildings, and encouraged public taste by the surest of all methods, the accustoming the eye to statuesque and architectural beauty. At Athens, as is usually the case, Poetry had the start of the kindred arts, but during the age of Pericles it attained to a greater height than had ever before been reached. The drama was then at perfection in the hands of Sophocles; and by enabling the poor to attend theatrical representations, Pericles nurtured their taste and increased his own popularity by thus throwing open the theatre to all. This precedent, whether made by Pericles or not, ultimately proved more ruinous to the state than any defeat. It made the people a set of pleasure-takers, with all that restlessness in the pursuit of pleasure which usually belongs to the privileged few. Another innovation, of which Pericles is supposed to have been the author, was equally injurious in its consequences, that, namely, of paying the dicasts in the courts. At first the pay was only moderate, but it operated as a premium on attendance at law suits, the causes became a mode of excitement for a people whose intellectual activity made them particularly eager for anything of the kind, and thence resulted that litigious spirit which is so admirably ridiculed in the 'Wasps' of Aristophanes. But we may well excuse mistakes of this kind, grounded probably on a false view of civil rights and duties, such as an Athenian, with the highest possible sense of the dignity of Athens, would be most likely to fall into. Pericles no doubt had an honest and serious wish to establish such an empire for Athens as should enable her citizens to subsist entirely on the contributions of their dependent allies, and like a class of rulers, to direct and govern the whole of that empire, of which the mere brute force and physical labour were to be supplied by a less noble race.

Pericles was descended, as we have seen, by his mother's side, from the family of Clisthenes, and he was thus implicated, according to the religious notions of those times, in the guilt of the murder of Cylon's partisans, which was committed at the very altars in the Acropolis. (Thucyd., i. 126; Herod., v. 70, &c.) The Lacedæmonians, before the actual commencement of the Peloponnesian war, urged on the Athenians the necessity of banishing the members of the family who had committed this offence against religion, which was only an indirect way of attacking Pericles and driving him into exile. The Athenians retorted by urging the Lacedæmonians to cleanse themselves from the guilt incurred by the death of Pausanias. [PAUSANIAS.]

Pericles lived to direct the Peloponnesian war for two years. His policy was that of uncompromising although cautious resistance, and his great effort was to induce the Athenians to consider Attica in the light merely of a post, to be held or resigned as occasion required, not of hallowed ground, to lose which was to be equivalent to the loss of all. In the speech which he made before war was declared, as it is recorded by Thucydides, he impressed the Athenians with these opinions, representing the superiority of their navy and the importance of avoiding conflicts in the field, which, if successful, could only bring temporary advantage —if the contrary, would be irretrievable.

At the end of the first campaign, Pericles delivered an oration upon those who had fallen in the war, as he had done before at the close of the Samian war. From that speech (at least if Thucydides reported well) we learn what Pericles considered to be the character of a good citizen, and we see in what strong contrast he placed the Spartan to the Athenian method of bringing up members of the state. This speech, the most remarkable of all the compositions of antiquity — the full transfusion of which into a modern language is an impossibility—exhibits a more complete view of the intellectual power and moral character of Pericles than all that the historian and biographer have said of him. The form in which the great orator and statesman has embodied his lofty conceptions, is beauty chastened and elevated by a noble severity. Athens and Athenians are the objects which his ambition seeks to immortalise, and the whole world is the theatre and the witness of her glorious exploits. His philosophy teaches that life is a thing to be enjoyed; death a thing not to be feared.

The plague at Athens soon followed, and its debilitating effects made restraint less irksome to the people; but while it damped their activity, it increased their impatience of war. In spite of another harangue, in which he represented most forcibly how absurd it would be to allow circumstances like a plague to interfere with well-laid plans, he was brought to trial and fined, but his influence returned when the fit was over.

In the third year of the war, having lost his two legitimate sons, his sister, and many of his best friends, by the plague, he fell ill, and after a lingering sickness died. Some beautiful tales are told of his death-bed, all tending to show that the calm foresight and humanity for which he was so remarkable in life, did not desert him in death. It is an interesting question, and one which continually presents itself to a student of history, how far those great men who always appear at important junctures for the assertion of some principle or the carrying out some great national object, are conscious of the work which is appointed for them to do. It would for instance be most instructive, could we now ascertain to what extent Pericles foresaw that approaching contest of principles, a small part only of which he lived to direct. Looking from a distance, we can see a kind of necessity imprinted on his actions, and think we trace their dependence on each other and the manner in which they harmonise. Athens was to be prepared by accessions of power, wealth, and civilization, to maintain a conflict in which, had she been vanquished, the peculiar character of Spartan institutions might have irreparably blighted those germs of civilization, the fruit of which all succeeding generations have enjoyed. But how should this be? Her leader must have been a single person, for energetic unity of purpose was needed, such as no cluster of contemporary or string of successive rulers could have been expected to show. That ruler must have governed according to the laws, for a tyrant would have been expelled by the [illegible] of the Spartans, as so many other tyrants were, or by the [illegible] of the commonalty, every day growing up into greater power. Moreover, without being given to change, he must have been prepared to modify existing institutions so as to suit the altered character of the times. He must have been above his age in matters of religious belief, and yet of so Catholic a temper as to respect prejudices in which he had no share, for otherwise in so intolerant an age he would probably have incurred the fate of Anaxagoras, and destroyed his own political influence without making his country one whit the wiser. He must have been a man of taste; he would not have been able to go along with and direct that artistic skill which arose instantly on the abolition of those old religious notions forbidding any departure from traditional resemblances in the delineation of the features of gods and heroes, otherwise he would have lost one great hold upon the people of Athens. If Pericles had not possessed oratorical skill, he would never have won his way to popularity, and later in life he must have been able to direct an army, or the expedition to Samos might have been fatal to that edifice of power which he had been so long in building. Lastly, had he not lived to strengthen the resolve of the wavering people when the troops of Sparta were yearly ravaging the Thriasian plain, the Peloponnesian war would have been prematurely closed, and that lesson, so strikingly illustrative of the power which a free people can exercise under every kind of fortune, lost to posterity.

Pericles's connection with Aspasia can hardly be passed over without a trifling notice. Some misunderstanding exists on this subject from not taking into account the fact that Aspasia was a foreigner. She came, it is true, as an adventurer to Athens, and it is also probable that she was the cause of the separation of Pericles and his first wife, the widow of Hipponicus. He lived with her after divorcing his wife, who consented to the separation, and he is said to have been strongly attached to her. The relation which subsisted between Pericles and Aspasia may have been of the same nature with the morganatic marriages at present in use on the Continent.* Whether the [illegible]

Pericles, from a bust in the British Museum.

---

* At all events it has been attempted to show that the same [illegible] not necessarily imply disgrace, that is, it is not synonymous [illegible] That Aspasia was originally a πόρνη, does not interfere [illegible] the [illegible] having afterwards attained to the relation of an ἑταίρα. It [illegible] that Plutarch himself apologises for the scandal he retails about [illegible] this apology is surely enough to counteract his assertion that [illegible] παιδίσκας ἑταιρούσας τρέφουσα.

of Aristophanes as to the real origin of the Peloponnesian war had any foundation we cannot now tell. It is hardly probable that a man like Pericles should have been a coarse and vulgar voluptuary. [Aspasia.]

(Thucydides; Plutarch, *Pericles*; Thirlwall's *History of Greece*; Clinton's *Fasti Hellenici*.)

PERICRA'NIUM, is the tough fibrous membrane which covers the bones of the skull, and bears the same relation to them which the periosteum does to the bones of the rest of the skeleton. [Bone.]

PERIDOT. [Chrysolite.]

PERIGEE, the point of the moon's orbit in which she is nearest to the earth. [Apogee.]

PE'RIGORD, a province of France, one of those included in the great military government of Guienne. It was bounded on the north by Poitou (a portion of which was prolonged so as to meet the boundary), on the north-east by Limousin, on the south-east by Quercy, on the south by the Agenois, on the west by the Bordelais, and on the north-west by Saintonge and by Angoumois.

Périgord was a compact district extending about 90 miles from north to south and about 70 from east to west, watered by the river Dordogne and its tributaries. It was subdivided into Haut or Upper Périgord, and Bas or Lower Périgord. These provinces were sometimes distinguished as Blanc Périgord and Noir Périgord. In the former were—Périgueux (population in 1831, 8700 town, 8956 whole commune; in 1836, 11,576), capital of all Périgord; Nontron (population in 1831, 2192 town, 3246 whole commune); Ribérac (population in 1831, 3934 commune); Bergerac (population in 1831, 5965 town, 8557 whole commune); Montignac (population in 1831, 2829 town, 3692 whole commune); and other places. In Lower Périgord the towns were, Sarlat (population in 1831, 5317 town, 6036 whole commune; in 1836, 6036 commune), Belvès, St. Cyprien, and others. Périgord is chiefly included in the department of Dordogne.

Périgord gets its name from its capital Périgueux, which has preserved, in an altered form, the name of the Petrocorii, the ancient Gallic inhabitants of the district. It subsequently was subject to the Goths, and then to the Franks, and under the Merovingian dynasty was included in the great duchy of Aquitaine. Under the Carlovingians, Périgord became a county, which came in the tenth century to the counts of Marche.

In consequence of a dispute with the inhabitants of Périgueux, the county of Périgord was declared to be forfeited to the crown, and bestowed on Louis duke of Orléans (A.D. 1399): it afterwards passed by sale to the family of Blois, counts of Penthièvre, and by subsequent changes became part of the inheritance of Henri IV., on whose accession to the throne (A.D. 1589) it reunited to the crown. A branch of the house of the counts of Marche and Périgord became lords of Grignols and princes of Chalais and Talleyrand: the late Prince Talleyrand was a descendant of this stock.

PE'RIGUEUX, a city in France, capital of the department of Dordogne, situated on the Isle, a feeder of the Dordogne, 262 miles in a direct line west-south-west of Paris, or 294 miles by the road from Paris through Orléans and Limoges to Bordeaux. It was known to the Romans by the name of Vesunna, capital of the Petrocorii, a Celtic nation, and, in common with the other Gallic capitals, assumed, near the close of the Roman period, the name of the people to which it belonged, Petrocorii, from which is derived the modern Périgueux. A tower, part of the remains of the ancient town, is still designated Vésone, an evident modification of the original name, and the suburb in which it stands retains the designation of La Cité. This tower is round, about 200 feet in circumference, with a wall 6 feet thick and 65 feet high, composed of square stones, and faced on the inside with a layer of brick and mortar; it has neither doors nor windows, and is supposed to have been built for a temple. There are some few ruins of an amphitheatre, the greater diameter of which is estimated to have been 274 French or nearly 290 English feet, of aqueducts, and of public baths. There are also some remains of the town wall, which now encloses some gardens and vineyards, and show by their construction and materials that they had been hastily rebuilt after some disaster. There is a Roman gate in tolerable preservation, and near the town are the remains of a Roman camp. Périgueux passed from the hands of the Romans into those of the Goths, and subsequently of the Franks. It was at an early period the seat of a bishopric. In the middle ages it was an object of contest to the French and the English (who were then masters of Guienne); in later times it was taken by the prince of Condé in the civil troubles of the minority of Louis XIV., and retaken by the townsmen, who were chiefly of the opposite party.

The town lies chiefly to the left of the road to Bordeaux, which just runs through the outskirts; and to a traveller passing it on that side presents an appearance to which the dark, narrow, crooked streets of the interior do not correspond.

The houses are, however, well built, mostly of freestone, and very lofty; and there are some agreeable public walks. The cathedral of St. Front is a Gothic building, with a tower about 190 feet high: in a chapel of this cathedral is a fine carving in wood of the Annunciation, a work of immense labour and exquisite finish. The office of the prefecture is the finest building in the city. The townhall is in the episcopal palace. The population of Périgueux in 1831 was 8700 for the town, or 8956 for the whole commune; in 1836 it was 11,576. The inhabitants manufacture light woollen goods, hosiery, felt and straw hats, leather gloves, braid, and paper; they carry on trade in corn, wine, grocery, liqueurs, pigs, poultry, game, especially partridges, truffles, which are gathered in the surrounding district, and truffle-pies. Wax-blanching is carried on. There are four yearly fairs. There are a college or high school, with a collection of philosophical instruments attached to it; a library of 16,000 volumes; a museum of natural history and antiquities, a botanic garden, and an agricultural society; also an hospital, a theatre, and public baths.

The diocese of Périgueux comprehends the department of Dordogne; the bishop is a suffragan of the archbishop of Bordeaux. The arrondissement is divided into nine cantons or districts, each under a justice of the peace, and comprehends 116 communes. The population in 1831 was 101,327.

PERIHE'LION, the point of the earth's orbit in which it is nearest to the sun. [Aphelion.]

PERILLUS. [Phalaris.]

PERI'METER, the circuit, or bounding lines, of a plane figure; a term usually applied to rectilinear figures only, but without any particular reason for the restriction.

PERIOD, a name given to the recurring part of a Circulating Decimal.

PERIODIC FUNCTIONS. The general consideration of periodic magnitude, that is, of magnitude which varies in such manner as to go through stated cycles of changes, each cycle being a reiteration of the preceding one, is the subject of Trigonometry. Though that science derives its name from the measurement of triangles (as geometry does from that of the earth), its resources have been cultivated and its methods expanded until no definition short of the preceding will express its object or convey an idea of its powers. In the article cited will therefore be explained the mode of measurement applied to periodic magnitude: the present one is intended for nothing more than to point out a peculiarity of some classes of algebraic functions which has procured for them the name of *periodic* functions.

The calculus of Functions considers only forms, and the operations necessary to convert one given form into another, or to satisfy equations in which some forms of operation are unknown. Periodic functions are those which, performed any given number of times on a variable, reproduce the simple variable itself. Thus $1-x$ and $-x$ are periodic functions of the second order, since

$$1-(1-x)=x, \quad -(-x)=x.$$

Again, $1:(1-x)$ is a periodic function of the third order, since, if we begin with x, and write $1:(1-x)$ for x three times in succession, we end with x also—

$$x, \quad \frac{1}{1-x}, \quad \frac{x-1}{x}, \quad x.$$

Periodic functions are remarkable in the calculus of functions for the simplicity with which questions connected with them can be solved, when compared with the difficulty of solution of cases in which non-periodic functions enter. Their principal properties are here briefly pointed out: for further information, consult Babbage's 'Examples of Functional Equations' (appended to Peacock's 'Examples'), or the article on the Calculus of Functions contained in the 'Encyclopædia Metropolitana,' where further references will be found.

Let ϕx be a function of x; abbreviate $\phi(\phi x)$ into $\phi^2 x$

$\phi(\phi^2 x)$ into $\phi^3 x$, &c.: then, if ϕ be a periodic function of the nth order, $\phi^n x=x$.

Let r be one of the nth ROOTS of unity, then rx is the simplest periodic function of the nth order; but very simple ones of the form $(1+bx):(c-kx)$ may be obtained by making

$$k=\frac{b^2-2bc\cos\theta+c^2}{2(1+\cos\theta)}$$

where θ means the nth part of any multiple of four right angles. For instance, if $n=4$, θ may $=90°$, and $\cos\theta=0$, whence $k=(b^2+c^2):2$; whence

$$\frac{2+2bx}{2c-(b^2+c^2)x}$$

is a periodic function of the fourth order.

Let θx be any function of x whatsoever, and $\theta^{-1}x$ its INVERSE function, so that $\theta\theta^{-1}x=x$; then if ϕx be a periodic function, $\theta\phi\theta^{-1}x$ is also periodic. Thus $1-x$ being periodic of the second order, so are log. $(1-\epsilon^x)$, $\sqrt{(1-x^2)}$, $\sin^{-1}(1-\sin x)$, &c. &c.

Let $\theta\phi\theta^{-1}x$ be called a derivative of ϕx; then if ϕx and ψx be two periodic functions of the nth order, either can in an infinite number of ways be made a derivative of the other. Thus one of the ways in which $1:x$ is a derivative of $-x$ is $\epsilon^{-\log. x}$. Let $1, r, r^2, \ldots. r^{n-1}$, be the n roots of unity, let P_0 be any function of x and y, and let P_1 be the same function of ϕx and ψy, P_2 of $\phi^2 x$ and $\psi^2 y$, &c. From the equation

$$P_0+rP_1+r^2P_2+\ldots.+r^{n-1}\,P_{n-1}=0,$$

find y in terms of x; say $y=\theta x$. Then will $\psi y=\theta\phi x$, or $\psi x=\theta\phi\theta^{-1}x$; that is, ψx is expressed as a derivative of ϕx.

For example, let $\phi x=-x$, $\psi x=1-x$, be the periodic functions, of the second order; then $r=-1$. Let $P_0=ax+by$, then the preceding equation becomes

$$ax+by+(-1)(-ax+b\,\overline{1-y})=0;$$

$$\text{or } y=\theta x=\frac{b-2ax}{2b},\ \theta^{-1}x=\frac{b-2by}{2a}$$

$$\theta\phi\theta^{-1}x=\frac{b-2a\{-(b-2bx):2a\}}{2b}=1-x.$$

The periodic functions, as before observed, are those whose relations are most easily obtained. For example, let αx, βx, γx, be given functions of x, and ϕx an unknown function, to be determined by the equation

$$\phi x=\beta x+\gamma x\,\phi\alpha x.$$

If αx be not periodic, there are two difficulties in the way, each most frequently insuperable: first, the determination of some one solution of this equation; secondly, the determination of the INVARIABLE function of this equation, or the solution of $\psi\alpha x=\psi x$. But when αx is periodic, both difficulties can be overcome and a general solution given. Say $\alpha^n x=x$, then ψx is any symmetrical function of x, αx, $\alpha^2 x, \ldots. \alpha^{n-1}x$; and if $B_0\,B_1$, &c., be βx, $\beta\alpha x$, &c., and $C_0\,C_1$, &c., be γx, $\gamma\alpha x$, &c., the general solution divides into two cases, in the first of which the solution does not depend on the invariable function.

The most general case gives

$$P_0=\frac{B_0+C_0B_1+C_0C_1B_2+\ldots+C_0C_1\ldots C_{n-2}B_{n-1}}{1-C_0C_1C_2\ldots.\,C_{n-1}}$$

In this case the preceding is the most complete and only solution. But if C_0 and B_0, &c., be such that the numerator and denominator of the preceding both vanish, the general solution is

$$n\phi x=\overline{n-1}\,B_0+\overline{n-2}\,C_0B_1+\overline{n-3}\,C_0C_1B_2$$

$$+\ldots.+C_0C_1C_2\ldots C_{n-3}B_{n-2}$$

$$+(1+C_0+C_0C_1+\ldots.+C_0C_1\ldots C_{n-2})\psi x.$$

For demonstration and extension, see the article cited in the 'Encyc. Metrop.,' §§ 192-198, and 235.

PERIODS OF REVOLUTION. In the present article we simply describe the names, commencements, lengths, and uses of those periods which it is most requisite the reader should find distinctly explained in a work of reference, premising some explanation of the way in which comparison of different periods gives new periods.

By a period we mean a definite portion of time, beginning from a given epoch, which being repeated again and again will serve to divide all time subsequent to the epoch (or precedent, if the repetitions be also carried backwards from the epoch) into equal parts, for the purposes of common reckoning and historical chronology. A period is then a fixed portion of time used for measurement, just as a foot or mile is used for measurement of length.

Periods may be divided into natural and artificial; the former immediately suggested by some recurrence of astronomical phenomena; the latter arbitrarily chosen. Since however time cannot be preserved and handed down as if it were material, it is natural that the knowledge of artificial periods should be preserved by representing the number of natural periods which they contain: nor is it to be supposed that artificial periods were ever invented in a perfectly arbitrary manner, or were indeed ever anything more than convenient collections of natural periods.

When one period is contained an exact number of times in another, each recommencement of the larger one is also a recommencement of the smaller one: thus the day being exactly twenty-fours, if any one day begin at the beginning of an hour, all days will do the same. But if the smaller period be not a measure of the larger, a longer period may be imagined, which in this article we will call a *cycle*, consisting of the interval between the two nearest moments at which the smaller and larger periods begin together. Thus a week of seven days and a month of thirty days give a cycle of seven months or thirty weeks, these two periods being equal. If however the two periods can be measured by a larger number of days, the cycle may be made smaller: thus, a month of 30 days and a year of 365 days, or a month of 6 times five days, and a year of 73 times five days, would give a cycle of 6 × 73 times five days, that is of 6 years or 73 months.

When two natural periods are expressed by complicated fractions of days, the method explained in FRACTIONS, CONTINUED, will serve to show nearly how many of one period make up an exact number of the other. Thus the tropical, or common, year being 365·24224 days, and the lunation being 29·53059 days, both approximate, it appears that 36,524,224 lunar months would be 2,953,059 years nearly. To reduce this long cycle to others more convenient for use, and as accurate as the number of figures employed will permit, proceed as in the article cited with the fraction

$$\frac{2{,}953{,}059}{36{,}524{,}224}$$

The quotients obtained are 12, 2, 1, 2, 1, 1, 17, &c. at which we stop, because the appearance of so large a quotient as 17, shows that the result of the preceding quotients is extremely near. The successive approximations derived from the first six quotients are—

$$\frac{1}{12}\qquad\frac{2}{25}\qquad\frac{3}{37}\qquad\frac{8}{99}\qquad\frac{11}{136}\qquad\frac{19}{235}$$

Or 235 lunations make 19 years very nearly.

The period in which all others are expressed is the day, which is not, as many suppose, the simple time of revolution of the earth, but [DAY] the average time between noon and noon. To distinguish it from other days it is called the *mean solar* day.

The year, or the time between two vernal equinoxes, is not a uniform period, nor does the average of one [illegible] period give *precisely* the same as another. [YEAR.] For chronological purposes however it is useless to take account of this variation, and 365·2422414 days, the year of astronomers in our day, may be considered as more than sufficiently exact for any time. In fact the year is made to consist, in the long run, of 365·2425 days, and a cycle of 400 years is necessary to the complete explanation of this fraction. Supposing the years from A.D. 2001 to A.D. 2400, both inclusive, each fourth year is leap-year, beginning with 2004, except only 2100, 2200, and 2300, which gives in the 400 years 365 days to each year, and 97 intercalated days; while adding 97 days to 400 years, adds on the average 97-400ths or ·2425 of a day, to each year. As it is of considerable [illegible] portance distinctly to comprehend an intercalated cycle, that is, one in which fractions are disregarded until they amount to a unit, when they are corrected, to use a common phrase, in the lump, we put down the effect of the correction which is made in this current year (1840), being leap-year. In 1836, immediately after the last intercalation was made, the sun was in the vernal equinox at about 39 minutes after one P.M. on the 20th of March, and the equinoxes then took place as follows:—

1836	Sun in equinox	at 1h 39m P.M.	March 20
1837	„	at 7h 23m P.M.	March 20
1838	„	at 1h 18m A.M.	*March* 21
1839	„	at 7h 1 A.M.	*March* 21
1840	„	at 0h 41m P.M.	March 20

The intercalation of the present year (but for which the sun would have come on the equinox at 41 minutes past noon on the *twenty-first*) has overdone the correction, bringing the equinox nearer to noon than in 1836 by 58 minutes. Now, this over-correction of nearly an hour in four years is set right by leaving out the correction three times in 400 years; a provision, the necessity of which may be imagined, though its exactness cannot be appreciated from the preceding rough calculation.

The Gregorian year, therefore (or the year in the Gregorian reformation of the kalendar), is a portion of a cycle of 400 years of 365 days, 97 of which have an additional day. [KALENDAR.] The Julian year, in use before the Gregorian reformation, is a portion of a cycle of 4 years of 365 days, one of which has an additional day. Without a perfect comprehension of the manner in which the incommensurability of the year and day is remedied, no progress can be made in the understanding of the nature and use of chronological periods.

An Æra means either the commencement of an indefinite reckoning, or of a succession of periods. In the article ÆRA will be found the complete description of the most important æras; but as it often happens that for reference the mere time of an obscure or uncommon æra is wanted without explanation, we subjoin an extensive list, merely giving the leading words, and the date A.D. or B.C. of the vulgar Christian æra. It is to be remembered that the birth of Jesus Christ must have taken place in the fourth year B.C. of this common æra. The figures following the years refer to months and days: thus A.D. 729.6.13 would stand for* the 13th day of June, A.D. 729. We do not mean to say that the events in the following list did take place in the years, far less in the months, or on the days, which are set down: but only that those who used them as æras, took them as having happened in those years, months, and days. Thus the death of Alexander, according to Clinton, took place in B.C. 323, which is most likely to be right; but if those who afterwards made an æra of this death, reckoned from the 12th of November B.C. 324, that day is the æra, whether the event happened then or not.

Gregorian reformation, or new style	A.D. 1582
English adoption of the Gregorian reformation . .	A.D. 1752

Among the various sources of confusion may be noticed —1, an old practice of astronomers who called the year immediately preceding and following the vulgar æra, not 1 but 0; 2, the discrepancies arising from different times of beginning the year. The most important of these to the English reader is the following:—Before the change of style in 1752, and from the fourteenth century to that time, the legal and ecclesiastical year began on the 25th of March, though it was very common in writings, &c., to begin it on the 1st of January. Hence January, February, and twenty-four days of March, were in one year, according to lawyers, &c.; and in another according to others. Thus the Revolution, so called, of 1688, took place in the February of that legal year, or, as we should now say, February, 1689. It is frequently written thus: February, 168$\frac{8}{9}$, or February, 1688-9. Thus, King Charles was beheaded January 30, 164$\frac{8}{9}$, or January 30, 1648-9.

We now come to the artificial periods which are of most use in chronological researches: these are—

1. The cycle of the sun, or more properly the cycle of Sundays.
2. The cycle of the moon, or of nineteen years, or of the Golden number, or of the Primes, or the Metonic cycle with its æra altered. [METON.]
3. The cycle of indictions.
4. The Paschal cycle.
5. The Julian period.

1. The cycle of the sun is a period of 28 years, compounded of 7 and 4, the number of days in a week, and the number of years in the interval of two leap-years. This, *in the old style*, makes the Sundays return to the same days of the year; every year of the cycle being in this respect exactly the same as the same year of the preceding cycle. Thus, the year A.D. 1 being the tenth in its solar cycle, and the DOMINICAL LETTER being for that year B, or the 2nd of January being Sunday, the 2nd of January was also Sunday in the year A.D. (1+28), or A.D. 29, also in A.D. (29+28), or A.D. 57, &c.

The series of dominical letters for the complete solar cycle is as follows:—attached to each dominical letter is what was called the *concurrent* of the year, meaning the number of days elapsed over and above a complete number of weeks, from the beginning of the cycle (not including the first day) to that of the year in question, the concurrent being written 7 where 0 would perhaps have been better.

1	GF	1	8	E	2	15	C	4	22	A	6
2	E	2	9	DC	4	16	B	5	23	G	7
3	D	3	10	B	5	17	AG	7	24	F	1
4	C	4	11	A	6	18	F	1	25	ED	3
5	BA	6	12	G	7	19	E	2	26	C	4
6	G	7	13	FE	2	20	D	3	27	B	5
7	F	1	14	D	3	21	CB	5	28	A	6

Connected with this table is one of what were called solar *regulars* (regulators would have been the modern term), one for each month, as follows:—

Jan.	2	Apr.	1	July	1	Oct.	2
Feb.	5	May	3	Aug.	4	Nov.	5
Mar.	5	June	6	Sept.	7	Dec.	7

The table given in DOMINICAL LETTER would save some of the following process, which however it is better to give.

Old Style.—To find the part of the solar cycle in which any given year is found. If the year be A.D., add 9 and divide by 28; the remainder (or 28 if the remainder be 0) is the year of the solar cycle required. But for a year B.C., deduct 10 from the date, and divide by 28; the remainder deducted from 28 gives the year. The dominical letter and concurrent are then taken from the preceding table. And to find on what day of the week the first day of any month fell, to the concurrent of the year add the regular of the month, the sum (diminished by 7, if it can be done) shows the day, 1 being Sunday, 2 Monday, &c. (But in leap-year one day later must be taken for every month after February.) Thus to find the day on which the æra of the Hegira fell, or July 16, 622 A.D., 622 + 9 or 631 divided by 28 gives the remainder 15, which is the year of the cycle. The concurrent is 4, which added to the regular of July 1, gives 5, or Thursday for the 1st July, and Friday for the 16th; whence Friday is the day required.

---

* There is some incorrectness, but great convenience in this. Astronomers now sometimes use such a notation as 1834·61, not to denote 1834 years and 61 100ths of a year, but the moment at which 61-100ths of the 1834th year have elapsed.

The perpetuity of the solar cycle, in the connection of its numbers with the dominical letters, &c., is destroyed by the new style, in which a similar cycle of no less than 2800 years exists. Up to the end of this century however, the cycle of 28 years, as it now exists, will remain undisturbed,* and it may therefore be worth while to give the years of the solar cycle answering to the decads of the century, and the table of dominical letters, concurrents, and regulars:—

1801, 18	1820, 9	1840, 1	1860, 21	1880, 13
1810, 27	1830, 19	1850, 11	1870, 3	1890, 23

	ED	1	8	C	2	15	A	4	22	F	6
2	C	2	9	BA	4	16	G	5	23	E	7
3	B	3	10	G	5	17	FE	7	24	D	1
4	A	4	11	F	6	18	D	1	25	CB	3
5	GF	6	12	E	7	19	C	2	26	A	4
6	E	7	13	DC	2	20	B	3	27	G	5
7	D	1	14	B	3	21	AG	5	28	F	6

Jan.	3	Apr.	2	July	2	Oct.	3
Feb.	6	May	4	Aug.	5	Nov.	6
Mar.	6	June	7	Sept.	1	Dec.	1

To find the first of April, 1836: the year is 25 of the cycle, and leap-year, and the concurrent 3 added to 2, the regular of April, with 1 allowed for leap-year, gives 6, or Friday.

2. The cycle of the moon is that of 19 years, which is very nearly 235 complete lunations, as follows:—the 235 mean lunations of 29·53059 days each make 6939·69 days, while 19 years of 365 days each give 6935 days, and, allowing 4¾ days for leap-years, 6939·75 days. Hence 235 lunations fall short of 19 Julian years by ·06 of a day, or one day in about 317 years. Hence during a period of 300 years, and as far as the mean place of the moon is concerned [EASTER], the new and full moons of the cycle of nineteen years would fall on the same days. On the assumption of 235 lunations exactly corresponding to 19 years, all the rules for finding Easter are founded; and in the steadiness with which this false assumption was held to, lies the value of this cycle in chronology. If the astronomers had been allowed to vary Easter according to the latest improvements in determining the moon's place, the chronology of the details of the different years of the middle ages, confused as it sometimes is, would rarely have been anything but confusion; in chronological reckoning nothing is of any importance compared with keeping to one unvaried rule; and the reformation (so called) of the calendar was, in our opinion, anything but an improvement.

In the article EASTER, the definition of that term is slightly† wrong (page 252). The paschal full moon is that which falls *upon* or next after (not next after only, as stated) the 21st day of March; and Easter Sunday is that which comes *next after* the day of the paschal full moon; so that the earliest possible Easter Sunday takes place when Saturday the 21st of March has a full moon, in which case Easter Day is Sunday the 22nd. Count 29½ days from March 21st (inclusive), beginning at midnight of the 20th, and we come to noon on the 19th of April; if this day be Sunday, the next Sunday is April 26, which it should seem then must be the latest possible Easter Day. But all the tables fix April 25 as the latest Easter Day, and this depends upon the meaning of the words 'full moon' as used by the authorities which settled the time of keeping Easter.

The Jews keep their Passover on that fourteenth day of the moon which follows the vernal equinox. The Nicene council (A.D. 325), believing the equinox to be always on the 21st of March, took that day as their equinox, and the fourteenth day of the moon next following as the guide to the Sunday which should be kept as Easter Day. The provision that if the fourteenth day were Sunday, the next Sunday should be kept, was meant to avoid ever keeping Easter on the same days as the Jews keep their Passover (which was an object of great moment in those days). Now the thirtieth day of the lunation, though partly belonging to the old moon, counts* as the first of the new one. Reckoning thus, we may see that if March 20 be the fourteenth day of the moon, April 18 is the fourteenth of the next moon, and April 2 the extreme limit of Easter Day.

Chronologists have two cycles of nineteen years each, the first of which is the cycle of nineteen years (so called), or the golden number, and the second, which begins three ye later, they call the lunar cycle. These of course only d in their time of commencement, the year 4 of the first cy being always 1 of the second. To show the manner in wh accuracy was attempted to be insured, it is worth while quote the date of one charter, from the 'Art de vérifier Dates,' particularly as all the dates are quite exact:—'A sunt hæc, anno ab incarnatione Domini MCIX., indic II., epacta XVII., concurrente IV., cyclus lunaris V., cy decemnovennalis VIII., regularis paschæ IV., terminus chalis XIIII. kal. Maii, dies paschalis VII. kal. Maii, lu ipsius (diei paschæ) XXI.'

This cycle of 19 years was used with an astronom carelessness which is surprising when it is considered th the due observance of Easter as to time was considered importance in a religious point of view. It is worth wh to describe it, since there are many persons who believe th there was a closer accordance between the paschal full m and that of the heavens than really took place. The A.D. 1 was the second of its cycle, so that by adding 1 to date, and dividing the sum by 19, the remainder gives year of the cycle in question; 19 being the year when remainder is 0.

The finding of Easter according to the old method is a w of prolixity, and the description of it, according to chron gical writers, is puzzling in the extreme. We shall only tempt to describe the result, which in fact amounted, thou it was not seen, to describing both the month and the year not in days, but in periods each a little shorter than day.

Let there be a cycle of 19 years averaging 365·25 days ea and let it be composed of 235 lunations, each of which ther fore must be 29·53 days. Take another period of time, a call it a *short day*, and let 30 short days make the mont 29·53 common days, then the year will consist of 37 short days, say 371 days exactly, or 12 lunations and 11 sh days. Hence the new moons of each year will take 11 short days earlier than in the preceding year. Take period of 30 common days beginning with March 21 a ending with April 19. These will very nearly coincide, ea to each, with 30 short days; and the old method am to confounding these 30 days with 30 short days, and ta the yearly acceleration of the times of full moon at 11 comm days. This may make an astronomical error of half a d and the effect of averaging the years, and treating the l years as common years, a quarter of a day more. To t must be added the continually increasing error ar from neglecting the difference between 19 years and months.

Proceeding as above, let it be supposed that in the year of the cycle there is a full moon on the 5th of Apr supposition which pervades the old method of fin Easter; if then we write down all the days from March to April 19 inclusive in a circle, and putting 1 opposite April 5, write 2 eleven days earlier, or opposite to Ma 25, write 3 eleven days earlier in the *circular* cycle (in w April 19 immediately precedes March 21), or oppos April 13, &c., and then write the dominical letter (wh always the same for the same day of the year) opposi each day of the month,—this will give the table of the style given in EASTER, which is here repeated, and since 18th is the last possible day of a paschal full moon, the days following the 19th may be Easter Sundays, and given with their dominical letters:—

---

* Since A.D. 1900 is not leap-year, the whole cycle will then be overthrown, but since A.D. 2000 is leap-year, it may be reconstructed so as to last till 2100.

† The error however is not carried any farther than the first paragraph. But the table in the first column of page 253, for the new style, extends only to A.D. 1900.

* We do not say that this was intended; but it was so in the structure rules nevertheless.

Mar. 21	C	16	Mar. 30	E	7	Apr. 8	G	—	Apr. 17	B	19
22	D	5	31	F	—	9	A	17	18	C	8
23	E	—	Apr. 1	G	15	10	B	6	19	D	—
24	F	13	2	A	4	11	C	—	20	E	
25	G	2	3	B	—	12	D	14	21	F	—
26	A	—	4	C	12	13	E	3	22	G	—
27	B	10	5	D	1	14	F	—	23	A	—
28	C	—	6	E	—	15	G	11	24	B	—
29	D	8	7	F	9	16	A	—	25	C	—

The following then is the mode of finding Easter in (say) A.D. 1237. The year of the solar cycle is 14, thus shown;—

1237
9
———
28)1246(44
Rem. 14. Dom. letter D by table.

The year of the cycle of 19 years is 3, thus shown:—

1237
1
———
19)1238(65
Rem. 3.

Now in the third year of the cycle of nineteen years, by the preceding table, the paschal full moon is on the 13th of April, and the next Sunday letter (D) in the list is opposite to April 19, which is therefore Easter Sunday.

The Gregorian corrections of the method of finding Easter amount to an occasional correction of the place of the paschal full moon in the first year of the cycle of 19 years. Tables which will do perfectly well for a century may be constructed in the same mode as that already described; one is given in the article cited. The following additional explanations may save some trouble to those who try to understand the older writers on chronology.

The epact of the year is usually stated as being the moon's age at the beginning of the year: this is a correct definition as to the epact of the Gregorian calendar, but not so as to that which preceded. The epact of the old calendar is a number depending on the year in such manner that the epact of the year, increased by what was called the lunar regular of any month, gives (with deduction of 29, if necessary) the age of the moon on the first day of that month; so that the age of the moon at the beginning of the year is the epact, together with the regular of January. Thus the epact of every year may be increased or diminished at pleasure, provided all the numbers in the table of regulars be as much diminished or increased; and different tables of epacts will be found in different works, the difference being of course compensated in the regulars, or else in the rule for applying them. The epact of each year of the cycle of 19 years must be 11 more than that of the preceding, abating 30 as fast as it arises; this must be the case in every table, and the most common table of epacts gives 29 as the epact of the first year of the cycle, 10 as that of the second, 21 as that of the third, &c. Corresponding to this, 9 is the regular of January, 10 of February, &c. It is not worth while to give the table, not only because it is now useless, even for old chronology, but because it fails for those years of the decemnovennal cycle in which two full moons come in the same month.

Again, the annual regular, or the regular cited in charters (as in our previous quotation, where it is called the paschal regular), is neither the solar regular described in the former part of this article nor the lunar regular just mentioned, but a third regular belonging to the whole year, and which, added to the concurrent previously described, gave (7 being abated, if necessary) the last day of the moon preceding the paschal moon. Thus A.D. 874, the concurrent being 4 and the annual regular 5, their sum 9 diminished by 7, or 2, gives Monday as the last day of the ante-paschal moon.

The paschal term (terminus paschalis) mentioned in the quotation, meant simply the fourteenth day of the paschal moon.

3. The Indiction was an edict of the Roman emperors, fixing the tribute, and as one such edict was supposed to have appeared every fifteen years, years were naturally reckoned according to their distance from the year of Indiction. There is doubt about the first origin of indictions, about their meaning and their earliest date· all we have here to do with is the fact, that from Athanasius downwards, they were more or less employed by ecclesiastical writers in describing epochs. The popes afterwards adopted this mode of dating, and the common Indiction[*] found in chronological tables begins so that A.D. 313 is the first year of the first cycle of Indiction, each cycle containing 15 years. At this rate A.D. 1 was the fourth year of an imaginary preceding indiction, and the remainder of three more than the date of any year divided by 15 will give its position in its cycle of Indiction. Thus 1239, increased by 3 and divided by 15, gives the remainder 12, or A.D. 1239 is the twelfth year of a cycle of Indiction.

4. The paschal cycle is one compounded of 28 and 19 years, or 532 years, during which time the cycles of the sun and of 19 years run through all their combinations, and recommence them again. According to the old system then, this is the cycle of Easter Days, which begin again in the same order when it is finished. A.D. 1 was the second year of the first paschal cycle, being also 2 of the cycle of 19 years, and 10 of its solar cycle. The paschal cycle of the Gregorian calendar would be 53,200 years.

5. The Julian period was imagined by Julius Scaliger, and is a combination of the solar cycle, the cycle of 19 years, and that of Indictions. Now 28 × 19 × 15 gives 7980 years, which is the length of the period in question. It was made to begin at a year B.C., which was the first year of each cycle, namely B.C. 4713 years. Hence, subtract any year B.C. from 4714, or add any year A.D. to 4713, and you have the year of the Julian period answering to the date used. The advantage (if it be one) of this period is, that by dividing the year in it by 28, 19, and 15, the remainders show the years of the different cycles belonging to the Julian date used, remembering when the remainder is nothing to substitute the divisor instead.

For the history of periods not absolutely used in chronology, see their several names, such as METONIC CYCLE, SAROS, SOTHIAC PERIOD, &c., &c.

Astronomical periods actually existing in nature, may be divided into—*days*, connected with the rotations of planets round their axes—*months*, connected with the rotation of satellites round their primaries—*years*, connected with the rotations of primary planets round the sun—and *secular* periods, connected with slow changes of the elements of orbits. The most convenient period of measurement is the civil or mean solar day at the earth, being the average interval between noon and noon. [SYNODIC REVOLUTION.]

This period being divided into hours, &c., the actual rotation of the earth is $23^h\ 56^m\ 4^s{\cdot}09$, and is called the sidereal day. The average interval between two transits of the moon over the meridian is $24^h\ 50^m\ 28^s{\cdot}32$, which might be called the mean tide-day. The rotation of the moon is the time of her revolution round the earth [MOON]: and the rotations of the planets are as follows (in *sidereal* time, so as to make 24^h the rotation of the earth):—

	h.	m.		h.	m.
Sun	25	12	Mars	24	39½
Mercury	24	5½	Jupiter	9	56
Venus	23	21	Saturn	10	29¼
Earth	24		Uranus unknown.		

Various months are described in the article MOON, the only ones here necessary to cite being the one already used, of $29^d\ 12^h\ 44^m\ 2^s{\cdot}9$, or $29^d{\cdot}53059$, the average interval from new moon to new moon, and $27^d\ 7^h\ 43^m\ 11^s{\cdot}5$, or $27^d{\cdot}32166$, the actual time of revolution of the moon in the heavens. The satellites of Jupiter, Saturn, and Uranus have revolutions round their primaries as follows:—

		d.	h.	m.		d.
Jupiter's	First S.	1	18	28	or	1·7691
	Second S.	3	13	14		3·5518
	Third S.	7	3	43		7·1546
	Fourth S.	16	16	32		16·6888
Saturn's	Ring	0	10	29		0·4370
	First S.	0	22	38		0·9427
	Second S.	1	8	53		1·3702
	Third S.	1	21	18		1·8878
	Fourth S.	2	17	45		2·7395
	Fifth S.	4	12	25		4·5175
	Sixth S.	15	22	41		15·9453
	Seventh S.	79	7	55		79 3296

---

[*] The first indiction of Constantine is variously stated to have been A.D. 312, 313, 314, and 315.

		d.	h.	m.	d.
Uranus's	First S.	5	21	25	5·8926
	Second S.	8	16	58	8·7068
	Third S.	10	23	4	10·9611
	Fourth S.	13	10	56	13·4559
	Fifth S.	38	1	48	38·0750
	Sixth S.	107	16	40	107·6944

The civil year is the *tropical* year, or the time of revolution of the sun from the vernal equinox to the same again. Owing to the motion of the equinox [PRECESSION], this year, or 365^{d} 5^{h} 48^{m} 49^{s}·7, or 365^{d}·2422414, is shorter than the actual revolution of the earth round the sun, which is 365^{d} 6^{h} 9^{m} 9^{s}·6, or 365^{d}·2563612. Again, the *anomalistic* year, being that in which the earth moves from its nearest point to the sun to the same again, is 365^{d} 6^{h} 13^{m} 49^{s}·3, or 365^{d}·2595981. The following is the list of the actual revolutions of the planets round the sun, each to a tenth of a day, including the verified periodic comets, as far as their times are known:—

	Days.		Days.
Mercury .	88·0	Ceres .	1681·4
Venus .	224·7	Pallas .	1686·5
Earth .	365·3	Biela's Comet	2460·0
Mars .	687·0	Jupiter .	4332·6
Encke's Comet	1210·0	Saturn .	10759·2
Vesta	1325·7	Uranus	30686·8
Juno	1592·7	Halley's Comet	75 to 76 years.

Of secular periods, the most important are, the revolution of the moon's node, in 18·6 years; of the earth's perihelion, from the vernal equinox to the vernal equinox again (the latter also moving), or 21,000 years; and the revolution of the equinoxes themselves, in 26,000 years.

PERIŒCI (περίοικοι), an old astronomical term for those who have the same latitude, but opposite longitudes.

PERIO'STEUM. [BONE.]

PERIO'STRACUM, Mr. Gray's name for the *epidermis* of shells. [SHELL.]

PERIPATETICS (περιπατητικοί) is the name given to an antient philosophical sect. It was so designated from the circumstance of its founder, Aristotle, being accustomed to deliver his doctrines while walking in the grove of the Lyceum in the suburbs of Athens. (For an account of the life and works of this philosopher, see ARISTOTLE.) There is scarcely any department of human knowledge of which the writings of Aristotle do not treat. It would far exceed the limits of this article to give a full detail of his opinions. Such of them only as characterised the school which he originated can be referred to, and even these must be briefly noticed. They have relation chiefly to his general physical and metaphysical principles. To his system of logic, with the additions subsequently made to it by his disciples, it is unnecessary particularly to advert. [ORGANON.]

From the obscurity which attaches to the writings of Aristotle, occasioned by the errors which have crept into them, the abstruseness of the topics which he discusses, and the brevity and conciseness of his style, it is somewhat difficult to ascertain with precision what his opinions really were. Previous to his time it was commonly supposed by those who had speculated respecting the origin of the universe, that there is an eternal substance from which bodies are made, and on which forms are impressed, and to which the name of matter was assigned. This matter was understood to have been always in motion, to consist of indefinitely small particles, and to have been collected and united in bodies by the agency of an intelligent principle. It was further supposed that the original particles had certain properties by which they differed from each other, and by which the constitution of the bodies which they composed was determined. Empedocles and others taught that there are four primary elements, which are the bases of all corporeal forms; Anaxagoras and his followers maintained that bodies exactly represent the form of each of their constituent particles; while Plato held that essential forms have an actual existence in the divinity, and that by the union of these with matter the formation of bodies is effected.

Rejecting all these theories, Aristotle assumed the underived and independent existence of two opposite principles. But since such principles by their contrariety would destroy each other, the existence of a third was requisite. These he conceived to be matter, form, and privation, the first two being the constituent principles of things, and the last being accidentally connected with them. The first matter was imagined to be entirely destitute of all qualities, to exist potentially, and to be the subject in which forms are made to inhere. Form he explained to be the essence of a thing, or that which constitutes it what it is. How the first matter and form were brought into union so as to produce bodies does not appear; unless nature, the meaning of which term, as employed by Aristotle, it is not easy to apprehend, accomplishes the union.

Aristotle distinguished causes into the material, the formal, the efficient, and the final; the first being that of which things are made, the second that by which they are what they are, the third that by the agency of which anything is produced, and the last the design of its production. Having thus provided for the existence of substances generally, Aristotle divides them into three classes: the eternal, as the heavens; the perishable, as the bodies of animals; and the immutable nature, or prime mover, as it was otherwise called. This prime mover, which occupies the place of God in his system, was considered to be an eternal, incorporeal, and simple intelligence, and the original source of all motion, being itself unmoved. Its agency extended directly to the first celestial sphere, and mediately through similar inferior intelligences to the lower spheres, and by them to the universe at large. The mode in which it operated to the production of motion seems to have resembled that by which the volitions of the human soul give rise to muscular action.

Sensible bodies were divided by Aristotle into simple and compound; simple bodies being those elements which result from the combination of primary matter and form, and compound bodies those which proceed from elementary combinations. In bodies thus distinguished there are certain active and passive qualities, which constitute their specific difference, and by which they mutually tend to transform each other into their own nature. In consequence of the action of the first mover, whether direct or indirect, on matter there is a continual succession of dissolution and reproduction; reproduction taking place when the essence of a body is entirely changed, and only an augmentation or diminution when its accidental qualities undergo mutation.

Such is an imperfect sketch of Aristotle's general doctrine of physics. His opinions respecting man may be shortly summed up. The principles of the soul and of animal he thought to be identical, giving them the common denomination of entelecheia (ἐντελέχεια), or perfect energy. The faculties of the soul he considered to be, the nutritive, by which life is produced and preserved; the sensitive, by which we perceive and feel; and the rational, by which we understand. The sensitive faculty takes cognizance of external objects by means of its organs, which are adapted to produce the various sensations of sight, hearing, &c. The senses receive forms or sensible species in the same manner as wax receives the impression of a seal. Fancy is the perception which results from the immediate operation of the senses; while memory is derived from fancy, and is the effect of images formed in the soul by the senses. The intellectual or rational faculty is of two kinds, either active or passive. Passive intellect receives the form of things, and is the seat of species. Active intellect is either simple or complex: simple when it engages in the close apprehension of its object; complex when it combines simple conceptions so as to engender belief. Intellectual action is theoretic when it contemplates what is simply true or false, and practical when it determines what is good or evil, and thus gives rise to volitions.

Whether Aristotle believed in the immortality of the soul or not, has not been clearly ascertained. From his notion that the soul is a power externally transmitted unto the body, it has been inferred that he held it to be mortal, and that it ceased to have a separate existence after the dissolution of the body.

Aristotle's school in the Lyceum was continued for about twelve years. In consequence of the hostility of his enemies, who accused him of propagating impious tenets, he retired, soon after the death of Alexander, to Chalcis, where he died. Before withdrawing from his public labours however he appointed Theophrastus, of Eresus in Lesbos, as his successor in the chair. The opinions of Theophrastus differed in some respects from those of Aristotle, but he taught with great success, and was attended by about two thousand scholars. He was followed consecutively by Strato of Lampsacus, Lycon, or Glycon of Troas, Ariston of Ceos, and Critolaus the Lycian. With Diodorus of Tyre, who came immediately after Critolaus, the uninterrupted succession of the Peripatetic school terminated, about the hundred and fiftieth olympiad. Among the early followers of the Stagirite, who did not fill the chair, were several eminent philosophers. The most distinguished of these were Dicaearchus, a Messenian, Eudemus of Rhodes, and Demetrius Phalereus.

The Peripatetic doctrines were introduced into Rome in common with the other branches of the Greek philosophy by the embassy of Critolaus, Carneades, and Diogenes, but were little known till the time of Sylla. Tyrannion, an eminent grammarian, and Andronicus Rhodius, were the first who brought the writings of Aristotle and Theophrastus into notice. The obscurity of Aristotle's writings tended much to hinder the success of his philosophy, but it nevertheless soon gained a considerable number of supporters. During the reign of the Caesars, it acquired all its ancient influence; and till the time of Ammonius, the preceptor of Plutarch, was taught with great purity. After that it was divided into two sects, consisting respectively of those who wished to adhere strictly to Aristotle, and those who were disposed to amalgamate his doctrines with those of other schools. Julius Caesar and Augustus patronised the Peripatetic philosophy. Under Tiberius, Caligula, and Claudius, its adherents, in common with those of other sects, were either banished or obliged to remain silent on the subject of their peculiar tenets. This was the case also during the greater part of the reign of Nero, although during the early part of it philosophy was favoured. The chief Peripatetics in the first century of the Roman empire were Sosigenes of Egypt, who wrote a commentary on Aristotle's treatise *De Coelo*, Boethus of Sidon, who is mentioned by Strabo as having been his fellow-student in the Aristotelian philosophy, and Nicolaus of Damascus in Syria.

Ammonius the Peripatetic made great exertions to extend the authority of Aristotle; but about his time the Platonists began to study his writings, and prepared the way for the establishment of the Eclectic Peripatetics under Ammonius Saccas, who flourished about a century subsequent to Ammonius the Peripatetic. Even after this period however some were still found who adhered exclusively to Aristotle. The most celebrated of these was Alexander of Aphrodisias, who was a public professor of the Peripatetic philosophy, under Septimius Severus, in Alexandria or in Athens. Many of the Eclectic Aristotelians wrote commentaries on his works, some of which are still extant. The principal of these writers were Themistius, who flourished during the reigns of Constantius and Theodosius the Great; Olympiodorus, who lived about a century later; and Simplicius Cilix, in the time of the emperor Justinian.

After this period, philosophy in general languished. But in that mixture of ancient opinions with theological dogmas which constituted the philosophy of the middle age, the system of Aristotle undoubtedly predominated. About the twelfth century it had many adherents among the Saracens and Jews, particularly in Spain; and at the same period also it began to be diligently studied, though not without much opposition, among the ecclesiastics of the Christian church. Out of this latter circumstance gradually arose the Scholastic philosophy, which took its tone and complexion from the writings of Aristotle, and which continued long to perplex the minds of men with its frivolous though subtile speculations. The authority of Aristotle received a severe shock at the Reformation, but it survived the fall of the Scholastic system. His opinions were patronised by the Roman Catholic church, on account of their supposed favourable bearing on certain doctrines of faith; and although Luther and others of the Reformers determinedly opposed them, they were maintained by such men as Melancthon, who himself commented on certain portions of the works of the Stagirite. Many individuals distinguished for their genius and learning exerted themselves to revive the Peripatetic philosophy in its primitive purity, nor did it cease to have numerous illustrious supporters until the time of Bacon, Grotius, and Des Cartes. (Aristot., *Phys.*, *De Coelo*, *De Gen. et Corr.*, *De Anima*; Diog. Laertius; Fabric., *Bibl. Graec.*; Cudworth's *Intell. Syst.*; Brucker, *Hist. Crit. Phil.*)

PERIPHERY, the Greek word for circumference; a term applied both to rectilinear and curvilinear figures.

PERIPNEUMONY. [LUNGS, DISEASES OF.]

PERIPTERAL, or **PERIPTEROS.** [TEMPLE.]

PERISCII (whose shadows move round). In those latitudes which are high enough to have the sun for twenty-four hours together, the shadows make complete revolutions, whence the inhabitants may be called Periscii (Περίσκιοι).

PERISTERA. [COLUMBIDAE, vol. vii., p. 375.]

PERISTERINAE. [COLUMBIDAE, vol. vii., p. 374.]

PERISTO'MIANS, Lamarck's name for a family of fluviatile operculated Trachelipods (Gastropods of Cuvier and naturalists), breathing water, consisting of the genera *Valvata*, *Paludina*, and *Ampullaria*.

M. Deshayes (*last edit. of Lamarck*) observes that though founded on natural characters, the family of *Peristomians* has not been adopted by the majority of authors. Cuvier, he remarks in continuation, referred *Valvata* and *Paludina*, in the first edition of the 'Règne Animal,' to his great genus *Turbo*; and though he recognised the analogy of the *Ampullariae* with the *Paludinae*, he did not the less place them in his genus *Conchylium*[*] near the *Phasianellae*. M. Deshayes thus continues:—'De Férussac, so often an imitator of Cuvier in the classification of shells, has imitated him here; and M. de Blainville himself, resting on anatomical observations, differs but little, in his 'Treatise on Malacology,' from the opinion of the latter. Nevertheless if we turn to what M. de Blainville says on the subject of the *Ampullariae* and the *Paludinae* in the 'Dictionnaire des Sciences Naturelles,' we shall there find his opinions opposed to his classification. M. de Blainville in fact, who had made a dissection of *Ampullaria*, finds the greatest analogy between the animals of this genus and those of *Paludina*. If then classifications are intended to approximate forms which resemble each other, why place the *Ampullariae* and the *Paludinae* in two distinct families?[†]

'In the second edition of the 'Règne Animal,' Cuvier has more nearly approximated the three genera of the family of the *Peristomians*, comprehending all three in his *Trochoid Pectinibranchians*. Since the anatomical work on the *Ampullariae*, by M. de Blainville, M. Quoy, in the zoology of the 'Voyage of the Astrolabe,' has given his observations on a large species, and we can now compare the organization of the *Ampullariae* with that of the *Paludinae*, on whose anatomy Cuvier published a memoir.'

M. Deshayes then goes on to state that he has himself been able to add to the observations already known some interesting facts on the organization of the *Ampullariae*. If, says he, we consider the shells and the opercula which close them, we find an indisputable analogy between them, an analogy so great in some species that one even doubts to which of the two genera they ought to belong. The affinities (rapports) of the *Ampullariae* and *Paludinae* are then, in the opinion of M. Deshayes, incontestably established; and these affinities, he adds, are so numerous, that it seems impossible to him to separate the genera. The *Valvatae* have also, he thinks, very great affinities with the *Paludinae*, from which they are nevertheless distinguished by the manner in which the animal carries its *branchiae*.

If, says M. Deshayes, in concluding his observations on this family, the additions with which science has been enriched since the works of Lamarck, have confirmed his family of Peristomians, it remains to be ascertained whether the family itself should not change its situation. It is evident that the genera which it contains closely approach those of the family of the Turbos; it would therefore be proper to place the *Peristomians* in the neighbourhood of the *Turbinaceans*, and to arrange them near the family of the *Neritaceans*, which has certainly less direct affinities with the Turbo family. It may be perceived that in a linear classification like that which must necessarily be followed in a work, it is impossible to express exactly the affinities, sometimes complicated, of the families of the same great group. To set forth these affinities, we know, says M. Deshayes, but one method, that of a classification with lateral or parallel branches; and it is particularly in the group of *Pectinibranchiata*, where the genera and species are so numerous, and the shell has the aperture entire, that the necessity of a better arrangement forces itself on the attention.

M. Rang, in his 'Manuel,' places *Paludina* at the head of the genera forming the *Turbines* of Férussac, the first family of the *Pectinibranchiata*. *Valvata* is also arranged in the same family between *Magilus* and *Natica*. *Ampullaria* is placed in the second family (the *Trochoides* of Cuvier), between *Nerita* and *Janthina*.

---

[*] In Cuvier's last edition of the 'Règne Animal,' the genus Conchylium is discarded, and then *Valvata* [illegible], and *Paludina* is placed between *Valvata* and *Littorina*. *Ampullaria* is placed next to *Phasianella*, and is followed by *Helicina*. These are all arranged under his family of *Trochoides*.

[†] In M. de Blainville's 'Manuel de la Malacologie,' *Ampullaria* is placed in the family of *Ellipsostomes*, between *Phasianella* and *Helicina*. *Valvata* and *Paludina* are arranged in the family of *Trochoides*; the first of the last named genera between [illegible] and *Cyclostoma*, and *Paludina*, which terminates the *Trochoides*, immediately after *Cyclostoma*. The *Ellipsostomes* immediately succeed the *Trochoides*.

The late Rev. Lansdown Guilding makes his family *Ampullariadæ* consist of the genera *Paludina*, *Pachystoma*, *Ampullaria*, and *Ceratodes*.

Mr. Swainson, in his newly published treatise on 'Malacology' (*Cabinet Cyclopædia*, 1840), reduces the *Ampullarinæ* to a subfamily of the *Turbidæ*, and this subfamily comprehends the following genera and subgenera: *Valvata*, *Ampullaria* (with the subgenera *Pachylabra*,* *Lanites* (Lanistes), and *Ceratodes*), *Paludina* (with the subgenera *Paludina* and *Nematura*), and *Meladomus*. The *Ampullarinæ* are immediately succeeded by the *Melanianæ*.

Valvata. (Muller.)

Generic Character.—*Animal* with a very distinct head prolonged into a sort of widened proboscis; tentacles very long, subcylindrical, slightly curving outwards, very much approximated at the base, pointed at the extremity; eyes sessile at the posterior side of their base; foot bilobate anteriorly; branchiæ long, pectiniform, more or less capable of being exserted out of the cavity, which is largely open, and provided at the right of its inferior edge with a long appendage simulating a third tentacle; male organ retiring within the respiratory cavity.

Shell discoid or conoid, umbilicated, the whorls rounded and distinct, the apex mammillated; aperture round or nearly round, its borders united and trenchant.

Operculum horny, round; its elements concentric and circular.

Mr. Swainson is disposed to regard *Valvata* as a subgenus of *Paludina*.

Valvata piscinalis, with its shell, creeping.
a, natural size; *b*, enlarged.

Geographical Distribution of the Genus.—This genus appears to have been found as yet in Europe and North America only. M. Deshayes, in his Tables, makes the number of living species four, and names *Valvata piscinalis* as the only species living and fossil (tertiary). In his last edition of Lamarck the number of recent species recorded is six.

Example, *Valvata piscinalis*.

Description.—Shell conoid, globose, subtrochiform, umbilicated, white; whorls four or five; apex of the spine obtuse.

Locality, &c.—This little shell, which has four complete whorls, without including the apex, inhabits rivulets and ponds in England and France, and is, in all probability, to be found in Europe generally.

Valvata piscinalis.
a, shell, natural size; *b*, *c*, magnified; *d*, operculum enlarged; *e*, glutinous masses of eggs on a leaf; *f*, mass of eggs enlarged.

Paludina. (Lam.)

Generic Character.—*Animal* furnished with a proboscidiform head; mouth toothless, but containing a small lingual bristly mass; tentacles conic, elongated, contractile; eyes at the external base of the tentacles; foot oval, with a marginal furrow at its anterior part; male organ very large, swelling up the right tentacle, whence it comes forth from an orifice situated near its base; anus at the extremity of a small tube in the flooring (plancher) of the respiratory cavity

Shell furnished with an epidermis, conoid, having the whorls of the spide rounded, and the apex mamma[illegible]; aperture rounded, oval, angular at the summit, the [illegible] united and trenchant.

Operculum horny, its elements concentric, with its [illegible] excentric

Paludina parvula, animal and shell magnified.
a, side view; *b*, seen from above. (Guilding.)

Lamarck states that the *Paludinæ*, many species of which have been confounded with the *Cyclostomata*, *Bulimi*, and *Turbines*, inhabit fresh waters almost generally, but some live also in brackish and even in quite salt waters. They breathe water only, like the *Valvatæ*, with which they have a great affinity; but their branchiæ are internal, and they are further distinguished from that genus by the form of the aperture, which is rather longer than it is wide, being modified by the last whorl, which presents an angle at its summit. Their habits he describes as being very nearly those of the *Lymneæ*, like which the *Paludinæ* may be often seen progressing at the surface of the water, foot uppermost.

M. Deshayes, in the last edition of Lamarck, remarks that Linnæus knew the most common species of *Paludina*, and referred it to his indigested genus of *Helices*, under the name of *Helix vivipara*. Müller withdrew the form from the genus *Helix*, and, believing that he saw sufficient affinities between it and the *Nerits*, united both genera under the latter name. Lamarck rectified the errors of former zoologists, gave the genus its proper place, and characterized it clearly; in this he was aided by the anatomical researches which Cuvier bestowed upon the large species of *Paludina* belonging to our fresh waters. M. Deshayes goes on to serve that the shells of the *Paludinæ* are generally delicate, oval-globose, rarely elongated, and subturriculate; the aperture, with a complete peristome, is always modified by the penultimate whorl, and terminates posteriorly by a more or less sharp angle. If a *Paludina* be placed perpendicularly it will soon be perceived that the plane of the aperture is entirely parallel to that of the longitudinal axis. A horny operculum, generally delicate, sometimes thicker and [illegible] calcareous, closes the shell exactly, and is very distinct from that of the *Turbines* and *Cyclostomata*; it differs also from that of the *Littorinæ*.

This operculum is not formed spirally; the summit is subcentral, and its growth is effected by laminæ superadded to its circumference.

Geographical Distribution of the Genus.—This form is widely spread. Species have been found in Europe, Asia, Africa, and America. The European species are the habitants of temperate climates. M. Deshayes observes that the greatest number of the species live in fresh waters, and that they are met with in a great number of various localities on the earth's surface. They appear nevertheless to be more common in the northern than in the southern hemisphere; but perhaps, as M. Deshayes remarks, the difference may be attributed to the state of observation. Some small species, he adds, live in brackish waters, where they are found in great abundance.

The number of recent species of *Paludinæ* given in the Tables of M. Deshayes is twenty-five, and of these *Paludinæ Achatina*, *unicolor*, and *impura* (*tentaculata*), are noted as living and fossil (tertiary). In the last edition of Lamarck, the number is twenty-one only, but this is below the mark, *Paludinæ Genicula* and *Magnifica*, *Conrad*, are, for instance, omitted.*

Example, *Paludina vivipara*

Description.—Shell ventricose-conoid, thin, diaphanous, very delicately striated longitudinally, greenish brown, [illegible] brown and obsolete transverse bands; five turgidly-rounded whorls, the suture strongly marked.

---

* This is substituted by Mr. Swainson for *Pachystoma* of Guilding, on the ground that the name has been already used in Ichthyology, but *Pachylabra* is a hybrid word, derived from Greek and Latin roots. '*Pachycheilus*' would be free from the last objection.

* Mr. Lea, of Philadelphia, who has added so much to our [illegible] branch of natural history, has published and figured collectively the [illegible] species (May 1, 1838):—*Paludina* [illegible], *hyalina*, [illegible], [illegible], *pallida*, and *Nicklinsiana*.

Locality, &c.—Fresh waters, rivers, and ponds of England, France, Germany, &c.

Paludina vivipara. (Female.)

a, Shell of an adult, with young [illegible]; b, operculum; c, young shell [illegible].

The genus *Nematura*, Benson, arranged by Mr. Swainson as a subgenus of *Paludina*, is thus characterised.

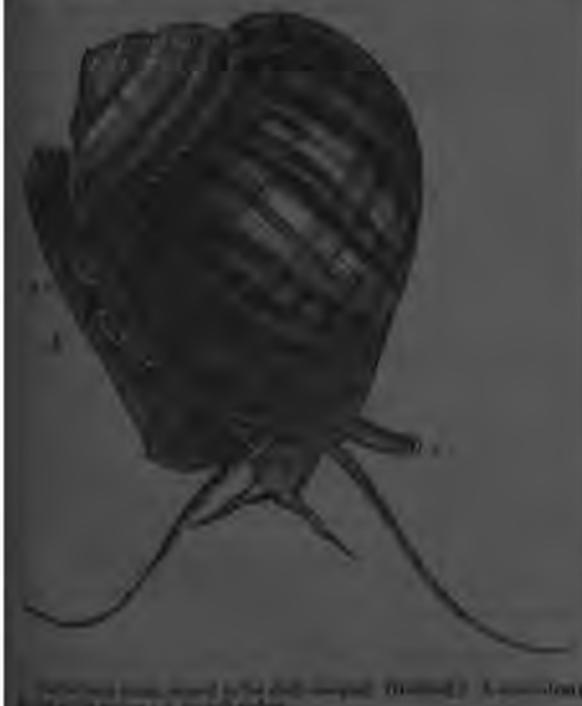
Shell thin, nearly oval, somewhat compressed from back to front; whorls few and rounded, spire acute, last whorl largest but contracted near the aperture; aperture small, oblique, rounded anteriorly; peristome continuous and thin; operculum spiral, horny, and with few volutions. Mr. Benson has described two recent and one fossil species, all these very minute, in the *Magazine of Natural History*, new series.

Ampullaria. (Lamarck.)

Generic Character.—*Animal* globular or planorbiform; *foot* large, delicate, and subquadrangular, largely truncated anteriorly. *Head* flattened, terminated anteriorly by a pair of conical buccal tentacula; two great subulate *tentacula* nearly as long as the foot, supporting at their base oculiferous peduncles, sometimes separated throughout their length. No jaws, but a lingual bristled ribbon. *A respiratory canal* formed by the mantle, but not leaving any trace on the shell. *Branchial cavity* of great size, largely open anteriorly, and whose upper wall is doubled so as to form a great aquiferous sac. (Deshayes, principally.)

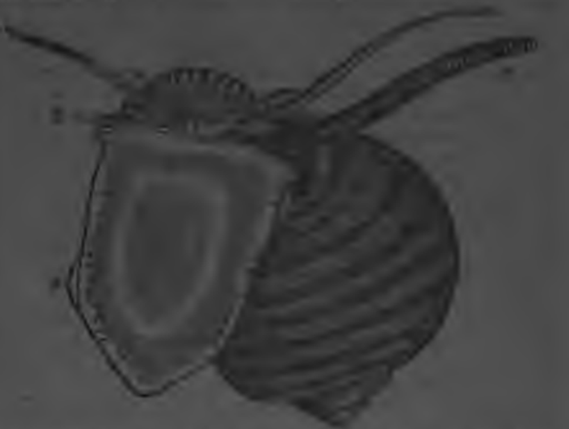
Shell furnished with an epidermis, generally not stout, but globular, ventricose, and umbilicated; spire very short, the last whorl much larger than all the others put together; aperture oval, rather longer than it is wide, borders united, the right lip trenchant.*

Operculum horny or shelly, rarely calcareous, rather delicate, composed of concentric elements, the apex submarginal and inferior.

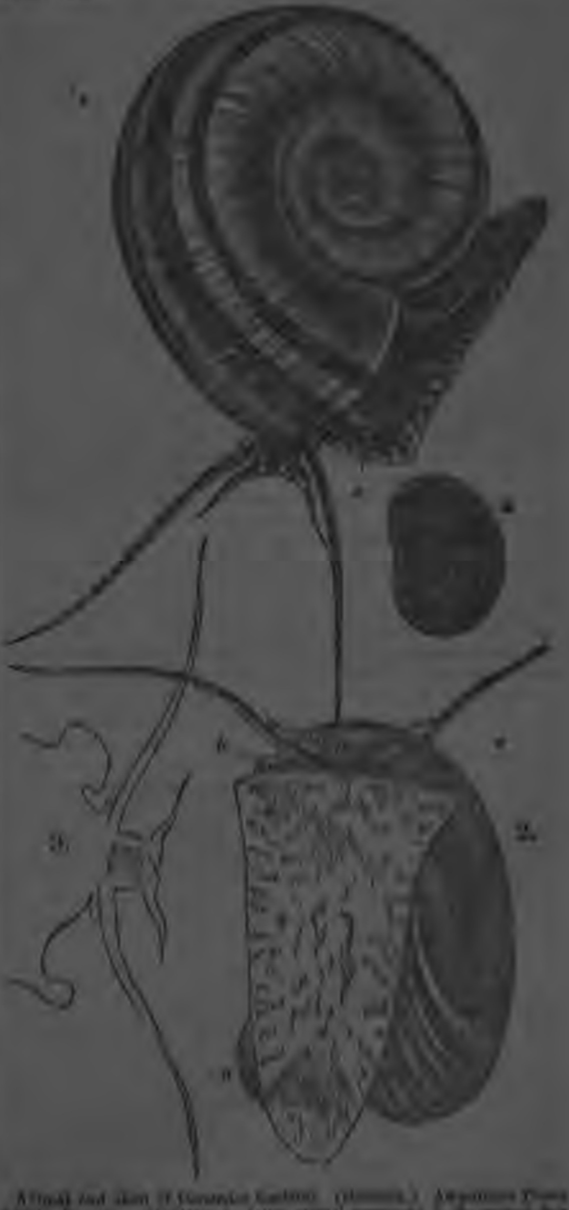


Ampullaria [illegible] (Quoy and Gaimard.) 1, operculum; [illegible]; b, the left siphon.

M. Deshayes (*last edition of Lamarck*), observes that all the operculated fluviatile shells were arranged by Müller in his genus *Nerita*. Linnæus confounded some of them with the *Helices*, and under these two generic denominations



Ampullaria [illegible] the upper side of the foot, &c. (Quoy and Gaimard.) The animal is represented as [illegible] to the surface of the water to breathe, and with the respiratory siphon expanded. a, the operculum; b, the right siphon; c, the left siphon.



Animal and shell of Ampullaria [illegible] (Lamarck.) Ampullaria [illegible] Africa, Senegal. (Adanson.) 1, the animal creeping; 2, the animal in a [illegible] position; a, operculum; b, the right siphon; c, the [illegible]; 3, head, tentacula, eyes at their base [illegible].

---

* In some species, it is [illegible].

were then indicated the small number of *Ampullariæ* known to those authors. Bruguière afterwards removed the species into his genus Bulimus, and Lamarck then established the genus under the name which it at present bears, without however any knowledge of the animal, and the absence of this information led him to comprehend under his genus many fossil species which have not its characters. ‘At present,’ continues M. Deshayes, ‘when the animal is known, and in consequence of the peculiarity of its organization many have been brought alive into Europe, we have presented to us the means of completing the characters of the genus and of rendering it more natural by the rejection of all the species which do not include all the characters, or in adding those which have been distributed among other genera. Thus it is, as we have already had occasion to observe, that the *Planorbis Cornu Arietis*, provided with an operculum, and the animal of which has been figured, belongs, in reality, to the genus *Ampullaria*. We are at a loss therefore for the motive which could determine Mr. Guilding to form the genus *Ceratodes* on this shell, when he had the opportunity of comparing the animal with that of *Ampullaria globosa*, animals in which it is impossible, judging from the figures which Mr. Guilding himself has given, to perceive generic differences.’

Before we follow M. Deshayes, as we presently shall, into an inquiry with regard to the organization of this remarkable genus, it becomes necessary to advert to the acuteness of Mr. G. B. Sowerby, who first pointed out, with all due deference to Lamarck, the true place of the *Planorbis Cornu Arietis* of that zoologist, and placed it among the *Ampullariæ*, in its true position. (*Genera*, No. 4.) For this he was sharply censured by Mr. Swainson, in his interesting *Zoological Illustrations* (title ‘Ampullaria Globosa,’ pl. 119). Specimens however soon came to hand with the operculum, thus destroying the principal ground of Mr. Swainson's severe criticism, and the knowledge of the animal soon extinguished all doubts as to the propriety of Mr. G. B. Sowerby's opinion. (See further, LIMNEANS (Planorbis), vol. xiii., p. 499.) We deem it necessary to call the attention of the student to this, that he may not be misled by the observations of a zoologist so justly distinguished as Mr. Swainson; indeed, he himself, by the position which he has assigned to *Ceratodes* in his lately published treatise on ‘Malacology,’ * virtually negatives his former judgment.

Ampullariæ have been, as has been before hinted, brought to Europe alive. The first, we believe, was sent to Paris by M. Caillaud from the Nile. That naturalist, during his voyage to Meröe, collected several Egyptian Mollusca, which he distributed generously among collectors. One correspondent had been anxious for the fluviatile mollusks found in the Nile. The person employed to collect these, after having gathered a large quantity of river mollusca, among which were some living *Ampullariæ*, put them all into a box of bran (son). This box was delayed on its road by the operation of the quarantine laws for four months, and when it reached M. Caillaud, was in such a state, from the putrefaction of the greater part of its animal contents, that he hastened to throw the whole into the water. To his no small surprise he found, a few hours after, the greater part of the *Ampullariæ*, which had been shut up with this mass of putrefaction, quietly creeping about upon the mud. He gave many individuals to M. Deshayes, who kept them alive from four to five months. The latter zoologist remarks that, since that communication, Mr. Sowerby, in the *Zoological Journal*, and M. Quoy, in the *Zoology* of the Astrolabe, have given the figures of many other species of *Ampullariæ*, many of which have been brought alive to Europe. We know of no other figures of *Ampullariæ* in the ‘Zoological Journal’ than those illustrative of the Rev. Lansdown Guilding's paper above copied.

On the 29th of October, 1833, Mr. Cuming, so well known for the great additions which he has contributed to our knowledge of the Mollusca by his collections from the west, and who is now employed in the same laudable pursuit in the east, brought to Mr. Broderip a specimen of *Ampullaria globosa*, expressing his opinion that it might be alive. Mr. Broderip immediately placed the specimen in a deep dish with some earth at the bottom, which was covered with New River water, and set it before the fire. On the 29th the animal gave no sign; but on the 30th it came forth and soon showed tokens of vigorous life. It was afterwards removed into a globular glass vase, such as is used for gold and silver fish, with a good layer of earth at the bottom. The water and earth were changed periodically, and the animal continued to live in apparently good health for many weeks. Its death was probably occasioned by the difficulty of resisting the low temperature of the long cold winter nights, where there were no stoves, in short nothing beyond the ordinary fires of a dwelling-house. The specimen is now in the museum of the Royal College of Surgeons.

M. Deshayes proceeds to observe that it became an object of inquiry how aquatic animals, unable to respire, except by means of a pectinated branchia, could remain alive so long out of the element apparently necessary to their existence. Nearly all the persons, he remarks, who occupied themselves with this phenomenon, thought that the animal retiring into its shell carried with it a certain quantity of water, which could not escape owing to the retention of the operculum, which closes the aperture with great exactness. Others thought that the humid air carried upon the branchiæ was sufficient to keep up the respiratory action. ‘Wishing to know,’ continues M. Deshayes, ‘whether there were anything in the structure of the animal which could explain the singularity, we soon perceived that the upper wall of the branchial cavity was doubled, and formed a great pouch, the aperture of which was placed backwards, above the origin of the branchiæ. Plunged in the water, the animal has this pouch constantly filled with the ambient liquid, and on retiring into its shell and shutting itself up under its operculum, this bag still remains filled with water, and this furnishes the necessary materials for the function of respiration. Everything leads us to believe that this is the cause which permits the *Ampullariæ*, pectinibranchiate aquatic animals, to remain a long time out of the water without perishing, and this explains also how it happens that in certain lakes which are annually dry, *Ampullariæ* are always to be found. When the great heats approach and they plunge themselves into the mud or sand, they preserve in their branchial sacs the quantity of water necessary for them during the whole time of drought.’

This is one of those beautiful provisions which meet the naturalist everywhere. The tropical torrent and lake may yield to the dry season and burning sun, but the Ampullaria, secure in the possession of his water-bag, can afford, like the camel in the desert, to wait till the rains furnish a fresh supply, and again fill the parched channel.

Geographical Distribution of the Genus.—The rivers and lakes of warm climates. Species, some of them very large (*A. Guyanensis*, *A. Urceus*, and *A. Gigas*, for example) have been found in Asia, Africa, and America, especially the southern portion of the latter. Olivier (*Voyage dans l'Empire Othoman*, &c.) states that one is found in Lake Mareotis, in company with marine shells, but he did not succeed in obtaining the living animal. Mr. G. B. Sowerby hesitates to admit into the genus another reverse species called by Olivier *A. carinata*, abundant in a neighbouring river, but which, says Mr. Sowerby, if we may judge by his representation, has a horny operculum, and should therefore rather be considered as a *Paludina*.

The Rev. Lansdown Guilding divides his genus *Pachystoma*, the second of his family *Ampullariadæ*, *Pomacea* being the first, into two sections. The genus is characterised as being furnished with a thick, marginated, and often with a channelled lip; the operculum shelly.

§ 1.

Umbilicus small: shell globose.

This section comprehends *Ampullariæ globosa*, *cornu-arietis*, and *puncticulata* of Swainson.

Umbilicus evanescent.

This section consists of only one species—*Ampullaria crassa* of Swainson

Mr. Guilding's genus *Ampullaria* is characterised by having a simple thin lip and a horny operculum, and is divided into three sections.

§ 1.

Shell globose; umbilicus comparatively large.

Ampullariæ fasciata, *sordida*, *luteostoma*, *reflexa*, and *leucostoma* of Swainson.

§ 2.

Shell oblong; umbilicus comparatively small.

Ampullaria oblonga of Swainson.

§ 3.

Shell globose; aperture narrowed; umbilicus very large and deep; columella obsolete.

---

* *Ante*, p. 462.

Ampullaria effusa of Swainson. Mr. Guilding is of opinion that this species forms the transition through *Ceratodes* to the *Planorbidæ*, and that it is probably more allied to that genus than to *Ampullaria*.

The genus *Ceratodes* of the last named author is characterised as having a simple lip; a horny operculum; a discoid shell; a very large and deep umbilicus, and an evanescent columella. The sole species given by him is *Ceratodes Cornu Arietis* above copied.

Mr. Swainson thus defines the genus *Ampullaria*:—Shell globose, rarely discoid, turbinate; spire very short; aperture oblong, pointed above, rounded below. The same author subdivides the four subgenera as follows:—

Ampullaria, Lam. Outer lip thin; operculum horny. Example, *Ampullaria fasciata* of Lamarck.

Pachylabra.* Outer lip thickened; operculum shelly. Example, *P. Globosa*, Sw.

Lanistes,* Montf. Shell reversed; the body-whorl ventricose only in the middle; outer lip generally thin. Example, *Lanistes Guinaica*, Sowerby's 'Manual,' f. 312. ('Malacology,' 1840.)

The number of recent species recorded by M. Deshayes in his Tables is twenty-four: in the last edition of Lamarck the numbers given are twenty-seven, including *Ampullaria avellana* and *fragilis*, of which we shall presently have occasion to speak more at large. Neither Mr. Swainson's *Ampullaria globosa*, Captain King's *Ampullaria Cumingii*, nor Mr. Lea's *Ampullaria Psalmon*, appears among these species. Mr. Swainson gives *Helix Ampullacea*, var. Gmelin, as a synonym of his *A. globosa*, but the former stands as a synonym for *A. fasciata*, Lam., in the last edition of the *Animaux sans Vertèbres*. Mr. Swainson considers it distinct, and quotes the description and figure of Chemnitz, who, like other authors, considered it a variety of *Helix Ampullacea*. The rivers of India are given as the locality, by Mr. Swainson.

Ampullaria globosa; the aperture closed by the operculum.

Some of these *Ampullariæ*, or *Apple Snails*, as they have been called by collectors, are of large size, as we have already stated; and some of these are figured in Lister, Chemnitz, and Spix: there are fine specimens, some from Mr. Broderip's collection, in the British Museum.

Ampullacera (Quoy.)

The *Ampullaria avellana* of Lamarck was founded on the *Nerita Nux avellana* of Chemnitz, and was placed by Bruguière among his *Bulimi*. Lamarck states that it was said to come from New Zealand. He observes that it is fluviatile and not marine, as Bruguière supposed it to be. Considering the state of information when Lamarck wrote, no better position could have been assigned to the shell than that in which he placed it. M. Quoy however, having had an opportunity of observing the animals of the so-called *Ampullariæ avellana* and *fragilis* alive, found, to his great surprise, that they presented none of the characters of the *Ampullariæ*. Upon further inquiry he ascertained that the anatomy of these animals constituted a particular type.

The following anatomical details are given by M. Quoy:—

The foot is large, transverse, yellowish, and separated by a furrow from the head, which has the form of a hood (chaperon) divided into two rounded lobes, deprived of tentacles, and supporting two very small sessile eyes on a fine yellow ground. Behind is a collar rather well formed by the border of the mantle, which only leaves a round hole at the right side for the entrance of the air, and offers a little more outwards the aperture of the anus upon a projecting infundibulated pedicle, as in *Auricula Midæ*. These parts, as well as those which the shell hides, are of a deep brown. The pulmonary cavity is large, and carries upon its floor (plancher) a large follicular depuratory organ, the aperture of which is readily seen on a very short anterior pedicle; the heart is behind it, and through the black pigment with which the floor is covered, a large vein is perceptible, which comes from the collar and goes along by the side of the rectum. After having lifted the partition which separates the abdomen, the œsophagus was found covered by two linear salivary glands fixed by their extremities. The stomach is not distinct, inasmuch as it leads into a globular gizzard (which is muscular and nervous, like that of a bird), containing in its interior four small depressions or fossets. The intestine which comes out of this gizzard, after having received the canals of the liver, which envelopes it, terminates by the rectum, without any apparent circumvolutions. The mouth is small and membranous. More externally is seen the exciting organ opening near the right eye, in the place where might be the tentacle of the same side. Behind it is a protractor muscle and a long tortuous canal. M. Quoy states that these parts are so delicate, that he has not been able to satisfy himself whether this canal is consequent and continuous with a similar one which is much longer, and envelopes the testicle, which is placed near the gizzard. At the right of the intromissive organ is the uterus, very convex backwards, where it receives the oviduct, which comes creeping along from the ovarium, which fills the posterior part of the tortuosity.

'Thus,' says M. Quoy, 'we have a mollusk breathing air although it lives in ponds, possessing the two sexes united, but being, notwithstanding, an insufficient hermaphrodite. It is apathic, and comes but little out of its shell, into which it retires very far upon the slightest touch. We found it sunk in the muddy sand, under some inches of saltish water, with its aperture full of earth. It is found in great abundance in New Zealand, where it is largely eaten by the natives.'

Generic Character.—*Animal* spiral, globular, convex; the foot short, quadrilateral, and with a marginal anterior furrow. Head large, flattened, notched into two rounded lobes supporting two sessile eyes, without the appearance of tentacles. Pulmonary cavity limited anteriorly by a collar, and having its aperture at the right border. Mouth membranous. Both sexes united.

Shell rather thick, globular, ventricose, deeply umbilicated, aperture round or oblique, with the borders united; spire short, but projecting.

Operculum horny, delicate, but little spiral, sometimes with a keel or projection. (Quoy.)

M. Deshayes adopts this genus, which he thinks one of the most interesting that has been for a long time discovered. 'It offers in fact,' says he, 'an entirely novel combination of an aquatic animal pulmonated and operculated, and fills up a lacuna. It is, with reference to the *aquatic pulmonata*, what the *Helicinæ* are with reference to the *terrestrial pulmonata*: *Ampullacera*, then, will constitute in the system not only a genus but a family, which ought to be placed at the end of that of the *aquatic pulmonata* without an operculum.'

Mr. Swainson (*Treatise on Malacology*, 1840) changes the name to *Thallicera*, as not liable, like *Ampullacera*, to be confounded with *Ampullaria*. He thinks that there can be no doubt that it is allied both to the operculated *Pectinibranchians* by its shell and its habitat, and to the pulmonary fluviatile *Limnacinæ* by its animal.

The only species known are *Ampullacera avellana*, Quoy (*Ampullaria avellana*, Lam.); and *Ampullacera fragilis*, Quoy (*Ampullaria fragilis*, Lam.). M. Deshayes refers to *fig.* 5, in Mr. G. B. Sowerby's plate of *Paludinæ* (*Genera*, No. xli.) for the last-named species.

Fossil Peristomians.

Valvata.—Mr. G. B. Sowerby states that he has never met with any other fossil species than those of a very recent lacustrine formation in Canada, and another in a volcanic stone from Auvergne, which he has figured in his *Genera*, No. xli.

M. Deshayes, in his Tables, notices only one fossil species (tertiary). In his last edition of Lamarck he records two, *Valvata multiformis* and *striata*; the first from the neighbourhood of Baden near Vienna, the second from Cefali near Catania.

* See ante, p. 455.

† M. [illegible] Lamarck [illegible] figured by Olivier from the canal of Alexandria (Egypt). It is not [illegible]

Paludina.—Mr. G. B. Sowerby states that the fossil species abound in a thin bed immediately above the fresh-water bed at Headen Hill, and also in the Petworth marble.

M. Deshayes remarks that the number of species found in a fossil state is considerable. Those on which no doubt can be thrown belong to the tertiary beds, and are particularly abundant in the fresh-water formations. Some species, he observes, are quoted from the secondary strata, but they are, in his opinion, doubtful, it being possible to refer the casts on which they have been established as much to the genus *Turbo* as to the genus *Paludina*. Many species, he adds, have been confounded with the *Cyclostomata* and the *Bulimi*, but their extreme abundance in the places where they are met with does not permit the belief that they are terrestrial shells; and as they have besides the greater part of the characters of the *Paludinæ*, M. Deshayes has referred them to this genus, in his work on the fossil shells of the environs of Paris.

The number of fossil species recorded by the last-named author in his Tables is forty-one (tertiary). This number, as regards fossil species only, is reduced to thirteen in his last edition of Lamarck.

Paludina vivipara is noted in Mr. Mantell's 'Tabular Arrangement of the Organic Remains of the County of Sussex' (*Geol. Trans.*, vol. iii., 2nd series), as occurring in the Weald clay and the Tilgate beds, and *Pal. elongata* from the latter locality. Both are also recorded from the Ashburnham beds (lower division of the Hastings deposits).

Paludinæ carinifera, elongata, fluviorum, Sussexiensis, and 'two or more species, probably new,' appear in Dr. Fitton's list, in his valuable paper 'On the Strata below the Chalk' (*Geol. Trans.*, vol. iv., 2nd series).

Ampullaria.—Mr. G. B. Sowerby states that he is not certain that any fossil species of this genus exists: several, he adds, are mentioned by Lamarck, in the 'Annales du Museum,' among the fossil shells of the environs of Paris; others, which are thought to be genuine, are found in the London clay at Hordwell, and in the mixed stratum between the two fresh-water beds at Headen Hill, in the Isle of Wight. (*Genera.*)

M. Deshayes is of opinion that many fossil species given as *Naticæ*, ought to find a place among the Ampullariæ; whilst others, such as *Ampullaria avellana*, for example, ought to constitute a new genus, or should be referred to the *Naticæ*, whose characters they possess. 'If,' says M. Deshayes, 'we compare the shells of the *Ampullariæ* with those of the *Naticæ*, we perceive differences, not only because in the *Naticæ* the shell is polished and without an epidermis, but also because the incidence of the aperture on the longitudinal axis is different in the two genera. Nevertheless we must not attach too great importance to this character, for we have actually before us a species of *Natica* from 'Terre-Neuve,' which M. Petit de la Saussaye sent us: it has the form of an *Ampullaria*, its shell is delicate, and has an epidermis, its umbilicus is without a callosity, and, notwithstanding its horny operculum, is entirely that of the *Naticæ*. The animal itself does not differ essentially from the other *Naticæ*, except in the amplitude of the foot, and in the mantle.'

M. Deshayes goes on to state that up to the time when he wrote (1838) there have hardly been found any fossil species of *Ampullaria* about which there is not some doubt. Those shells which he has retained in the genus, from the character of the aperture and the small thickness of the shell, are, he says, never met with except in marine formations, and one may always suspect that the animals which produced them were different from those of the *Ampullariæ* properly so called. As these species have the characters of *Ampullariæ*, and we have no means of ascertaining the analogy of the animals, we are obliged to have recourse to the characters of the shells and to determine from them alone. But a little time since, he remarks, the belief was general that fossil *Ampullariæ* belonged exclusively to the tertiary beds; but it is now known that this genus occurs through all the 'terrains de sédiment,' for Mr. Sowerby has recorded a fine species in the transition beds, and M. Deshayes says that he knows many others in the oolitic series, and even in the lower chalk. (*Last edition of Lamarck.*)

The number of fossil species recorded by M. Deshayes in his Tables is fourteen (tertiary). In the last edition of Lamarck the number is sixteen.

The genus occurs in the list of the fossils of Lower Styria, given by Professor Sedgwick and Mr. Murchison, in their valuable paper 'On the Structure of the Eastern Alps' (*Geol Trans.*, vol. iii., second series), and in Mr. Mantell's 'Tabular Arrangement of the Organic Remains of the County of Sussex' (*ibid.*).

In the last-mentioned catalogue *Ampullariæ patula* and *sigaretina* are noted from the blue clay of Bracklesham and the arenaceous limestone or sandstone of Bognor. The form also occurs with a ? in the list from the chalk marl, and *Ampullaria canalicuta* is recorded in the same paper as occurring in the gault, or Folkstone marl.

PERISTO'MIUM, in mosses, is the ring or fringe of bristles or teeth which are seated immediately below the operculum, and close up the orifice of the seed-vessel. This organ is highly hygrometrical, and is supposed to assist in dispersing the spores, or seed-like particles by which these plants are propagated. Professor Lindley regards the fringes of the peristomium as incomplete leaves.

PERITONE'UM is the membrane by which the walls of the abdominal cavity are lined, and all the abdominal organs are covered. The name is also sometimes applied to the cavity itself. The arrangement of the peritoneum is in every respect similar to that of other serous membranes [MEMBRANE], except that at the extremity of the Fallopian tube it communicates with the mucous membrane of that tube, and thus is indirectly exposed to the external air. It is the peritoneum, and the epithelium covering it, which gives to all the organs within the abdomen their peculiar shining surfaces, and which by its duplicatures forms the mesentery, omentum, and other folds by which those organs are attached to each other and to the wall of the abdomen, and through which their vessels pass. [MESENTERY; OMENTUM.]

PERITONI'TIS is an inflammation of the peritoneum. It may exist either as an acute or as a chronic disease. The chief symptoms of the acute form are pain, swelling, and tenderness of the abdomen, accompanied with fever and a frequent small and hard pulse. The pain in peritonitis is usually much more severe than that of any other inflammatory disease of the intestines or other abdominal organs. It is acute and cutting, and sometimes occurs in paroxysms; it is generally diffused, but occasionally it is almost confined to a single part of the abdomen; but its most distinguishing character is that it is greatly increased by pressure, and in a severe case the patient cannot support so much as the weight of the bed-clothes, but lies on his back with his knees drawn up, and breathes quickly and lightly, moving the diaphragm as little as possible, so as to avoid the pain which pressure would excite in the inflamed parts. The bowels in cases of peritonitis are usually, but by no means constantly, constipated; commonly also there are present nausea, vomiting, and hiccup, and almost always excessive thirst and prostration of strength. If not checked in its course, acute peritonitis usually terminates fatally in from five to ten days, the patient becoming more and more depressed, and all the symptoms regularly increasing till within a short time of death, when the pain commonly ceases, and a deceptive improvement in many of the other signs of the disease takes place.

The usual morbid effects of peritonitis are the effusion of serum with lymph or pus into the cavity of the abdomen, and adhesions of the opposite surfaces of the several organs within it. After death from acute peritonitis, the walls of the abdomen and the surfaces of the organs chiefly or all affected, are found thickened, swollen, and vascular, often with blotches of dilated blood-vessels, and more or less firmly adhering together by the lymph which is effused between them, and which, if the patient survives for a certain length of time, becomes vascular, and is converted into the usual tissue of adhesions or false membranes. [INFLAMMATION.]

The causes of peritonitis are various. Like other acute inflammations, it may occur after exposure to cold, or other common excitants of disease; but it is more commonly produced by injuries of the peritoneum, as by tumours developed within the abdomen, by the obstructions which occur in strangulated hernia, and intussusception, of which it is a constant consequence, by the spreading of disease from adjacent viscera, by heavy blows and falls on the abdomen, by penetrating wounds inflicted in operations for hernia and in other circumstances, by the passage of foreign bodies into the cavity of the abdomen, and especially by the ulcerative perforation or accidental rupture of any of the organs [illegible] tained within it, and the escape of their contents, circumstances which are productive of the most certainly and rapidly fatal form of the disease.

From these causes acute peritonitis may occur at all periods of life, but it more frequently affects persons of the middle age than any others. Women in child-bed are peculiarly liable to it. They may be attacked either with common peritonitis, presenting no remarkably peculiar symptoms or effects; or they may have that which is especially called puerperal peritonitis. In cases of the latter disease however the peritonitis is not always the most important symptom, but must rather be regarded merely as one of the accidents of the peculiar fever by which the patient is affected, and which often assumes the character of an epidemic.

The appropriate treatment of peritonitis consists in the early employment of copious general bleedings. The quantity of blood abstracted must be as great as the patient's health will permit; and after one full bleeding, it is usually advisable to abstract other small quantities at intervals of from six to twelve hours till the severity of the disease is distinctly reduced. When this has been effected, or even coincidently with the general bleedings, blood should be drawn from near the seat of the disease by the repeated application of numerous leeches, and hot fomentations should in the intervals be assiduously applied to the abdomen. Of internal medicines the most effectual is calomel, of which, after the first general bleeding, three or four doses of five grains or more, with one or two grains of opium, should be given at intervals of about four hours, and afterwards smaller doses till a slight salivation is produced. During all the time of the treatment, the lowest diet only should be allowed, unless the patient is evidently sinking. In that case, and generally in the later stages of the disease, a more nutritious diet may be given, but there is perhaps no affection in which relapses are so liable to occur in consequence of the early or injudicious use of stimulating food.

Acute peritonitis sometimes, after fifteen or twenty days' continuance, assumes a *chronic* form; or the inflammation may from its commencement be of slow progress. In either case the symptoms are usually very obscure; the pain being but slight or discoverable only by considerable pressure, and the swelling or tension of the abdomen occurring only at a late period of the disease. Its most important symptoms are the low fever, the constant thirst, the hectic flushings of the face, the emaciation, languor, and regularly increasing debility by which it is accompanied. It rarely proves fatal till after many months have elapsed; and its effects are found after death to be thickening and increased density of all the peritoneal coverings, increased vascularity or blackness of their surfaces, which in many cases are beset with vast numbers of minute greyish-white tubercles, and effusions of serum with lymph or pus wherever the adjacent organs are not connected together by the adhesions. The treatment of chronic peritonitis is usually unsatisfactory and of doubtful benefit. Local bleedings should be frequently employed, and blisters or other counter-irritants should be applied over the abdomen. The diet should be light and nutritious, and, as often as they seem necessary, mild purgatives may be administered. Frictions of ointments containing mercury or iodine are also useful, and iodine should be administered internally when the patient is of a scrofulous constitution.

PERIWINKLE, or **PEERIWINKLE**, the vernacular name for the well known species of *Turbo* which is hawked about the streets and sold in great quantities, especially to the poorer classes. In very hot weather and the decline of the year they are often unwholesome, especially if there be any predisposition to disordered functions of the abdominal viscera prevalent. Instances have been known where the introduction of a cargo of periwinkles into a village has been followed by a fearful amount of death consequent upon attacks similar to cholera, if not cholera itself. Taken in moderation and when in high condition, they do not seem to be an unhealthy food. The Linnæan name for the species is *Turbo littoreus*. Pennant states the belief of the Swedish peasants that when these shells creep high up the rocks, they indicate a storm from the south. Linnæus quotes Ström, the *Norwegian*, for a different augury when it creeps up the strand; he says that it denotes a land wind and a calm at sea,—'quando littora adscendit, indicat ventum à terra, pacatum ad litus.' The food of the periwinkle is generally considered to be vegetable only. [TURBINIDÆ.]

PERIZONIUS, JAMES VOORBROEK, born at Dam in the province of Groningen, in 1651, studied at Deventer and afterwards at Leyden under *Grævius*. He chiefly applied himself to philological and historical studies. In 1674 he was appointed rector of the gymnasium of Delft; in 1681 he was made professor of eloquence and history at Franeker. In 1693 he removed to Leyden as professor of history and the Greek language. He died at Leyden in 1715. Perizonius was one of the most distinguished scholars that Holland has produced. He published numerous dissertations on subjects of classical learning, and editions of Qu. Curtius, of Dictys Cretensis's 'Trojan War,' and of other Latin and Greek authors. Niceron, in his 'Mémoires,' has given a list of his works, which however is not complete. Among his more important works, the following deserve notice: 1, 'Animadversiones Historicæ, in quibus quamplurima in priscis Romanarum rerum utriusque linguæ auctoribus notantur; multa etiam illustrantur atque emendantur,' 8vo, Amsterdam, 1685. In this work the author compares many passages of various historians relating to particular events, and also to other subjects of language, habits, and civil polity; it is a work full of erudition, and useful to classical scholars; 2, 'De Usu atque Utilitate Græcæ Romanæque Linguæ;' 3, 'Rerum per Europam Sæculo XVI gestarum Commentarii historici,' a work imitated by Russell, in his 'History of the Sixteenth Century;' 4, 'Disquisitio de Prætorio;' 5, 'Dissertatio de Ære Gravi;' 6, 'Dissertatio de Morte Judæ;' 7, 'Origines Babylonicæ et Ægyptiacæ,' 2 vols. 8vo, Leyden, 1711; a work, the importance of which has been superseded by the more recent investigations into Egyptian chronology and antiquities. The 'Opuscula Minora' of Perizonius, consisting of orations and dissertations, were published at Leyden in 1740, with a biography of the author. Perizonius left his MSS. to the Leyden library.

PERJURY, by the common law of England, is the offence of falsely swearing to facts in a judicial proceeding. To constitute this offence the party must have been lawfully sworn to speak the truth by some court, judge, or officer having competent authority to administer an oath; and, under the oath so administered, he must wilfully assert a falsehood in a judicial proceeding respecting some fact material to the subject of inquiry in that proceeding. In a legal sense therefore the term has a much narrower import than it has in its popular acceptation. It is said by Sir Edward Coke (3 *Inst.*, 166) that 'the deposition must be direct and absolute, and not *as I think*, nor *as I remember*, nor *as I credit*, &c.;' but this doctrine has been long since exploded; and it is now clear that a person may commit perjury by swearing that he *believes* a fact to be true which he *knows* to be false. It is immaterial, with reference to the offence of perjury, whether the false statement has received credit or not, or whether any injury has been sustained by an individual in consequence of it. The characteristic of this offence therefore, by the law of England, is not the violation of the religious sanction of an oath, nor the wrong done to the person or property of another, but the injury done to the administration of justice by false testimony or information in a judicial proceeding. (*Fifth Report of Commissioners on Criminal Law*, p. 23.)

The history of this offence in the common law is entirely dependent upon the history of the trial by jury. [JURY.] Where perjury is mentioned by Bracton and Fleta, these ancient authors exclusively allude to the offence of jurors in giving a wilfully false verdict; and as the jury appear to have been originally merely witnesses, speaking from their personal knowledge of the facts, and sworn to *speak the truth*, their misconduct in giving a false decision might be justly treated as perjury. As population and civilization increased, the character of the trial by jury was changed, and witnesses were called in order to inform the jurors respecting facts of which the latter were commonly ignorant, though the institution was originally founded upon the presumption that they must necessarily be acquainted with them. It is probable that this alteration did not take place at once, but that it was one of those gradual introductions by means of which laws silently adapt themselves to changes in national habits and circumstances. At all events, there is no trace in the statutes, or in the reported proceedings of the courts, of any penal law against perjury in witnesses, as distinguished from that of jurors, earlier than the reign of Henry VIII.; the date of the introduction of the witness's oath to speak the truth, in use at the present day, is unknown, and no form of process for securing the attendance of witnesses (except where they were added to the jury) seems to have existed before the reign of Elizabeth. [JURY.] These facts tend to show that the offence of perjury has been gradually moulded into its present definite character, by the corresponding change in the functions of the jury. This change however was complete in the time of Sir Edward Coke, as he defines perjury nearly in the same terms in which it is described in more modern text-books. (3 *Inst.*, 163.)

A defendant in equity is guilty of perjury by false swearing in his answer to a plaintiff's bill. The defendant is in fact also a witness, for he is bound to answer on oath to the matter contained in the bill, and the plaintiff may read the whole or any integral portion of the defendant's answer as evidence against such defendant. In the case of an answer in equity, the offence of false swearing falls exactly within the definition given at the head of this article.

The punishments of perjury by the common law were, discretionary fine and imprisonment, and the pillory, which latter punishment was abolished in 1837. To these was added an incident probably derived from the punishment of jurors in antient times, namely, a perpetual incapacity to give evidence in courts of justice. A further punishment was authorised by the statute 2 George II., c. 25, s. 2, by which it was enacted that imprisonment with hard labour for seven years might be awarded, or transportation for a like period.

Subornation of perjury consists in wilfully procuring any person to commit perjury; and it is essential to this offence that the false oath should be actually taken. The same punishment is assigned to subornation as to perjury.

Besides perjury and subornation of perjury at common law, the statute 5 Eliz., c. 9, contains a legislative enactment respecting these offences; but as this enactment is more limited than the common law, both in the definition of the crime itself and in the punishment to be applied to it, it has seldom been used in recent times; and within the last century there have been few if any instances of prosecutions under this statute. There are also many statutes by which oaths are required as a sanction to statements of facts under a variety of circumstances, and otherwise than in judicial proceedings; and these statutes frequently declare that false swearing in such cases shall amount to perjury, and be punishable as such. The Commissioners on Criminal Law have pointed out the practical objections to provisions of this kind, and have suggested a mode of rendering the law upon the subject more precise by drawing a line of distinction between the dangerous crime of false testimony in courts of justice and mere false swearing to facts on other occasions. See *Fifth Report*, pp. 25 and 50.

By the 5 & 6 William IV., c. 62, declarations may now be substituted for oaths in many extrajudicial proceedings. [OATH.]

PERM, an extensive government of Russia, is situated partly in Europe and partly in Asia, between 56° 30′ and 61° 30′ N. lat. and 53° 20′ and 64° 10′ E. long. It is bounded on the north by Wologda and Tobolsk, on the east by Tobolsk, on the south by Orenburg, and on the west by Viatka. The area, according to Schubert and most other writers, is about 125,000 square miles, or more than double the area of England and Wales. The population, according to Schubert, is 980,000, but according to Hörschelmann and Cannabich, it is 1,270,000; M. Köppen however made it amount, in 1838, to 1,488,800.

This government is mountainous, and is divided by the Ural mountains, which traverse it from north to south, into two unequal parts, the smaller of which is in Asia. But though the loftiest summit of the Ural chain, the Pavdinskoï-Kamen, is 6400 Paris feet above the level of the sea, the chain rises so gradually that travellers approaching it on the road from Perm to Ekaterinenburg are disappointed in finding themselves at the summit (which, on this road, it is true, is only 1500 feet) without perceiving that they were making an ascent. The breadth of the chain varies from seven to seventy miles, and the part belonging to the government of Perm is 460 miles in length. The mountainous parts are covered with forests, in some of which there are immense marshes. The southern parts of the government, on the European side, are fertile and well cultivated, but the other portions are more suitable to pasture than tillage. The course of the rivers is determined by the Ural chain. The principal river on the west side is the Kama, among the numerous affluents of which is the Tchoussovaia, which flows from some lakes at the foot of the chain, and joins the Kama above the town of Perm. On the other side of the mountains, the Sosva, the Toura, and the Sceth flow eastward to join the Tobol. There are above [illegible] lakes, most of them east of the mountains. There are also sulphureous and other mineral springs. The climate is unequal, being very rigorous in the mountains and in the eastern part, but milder towards the south-west. It is however generally healthy. Agriculture employs a great number of hands, but the government does not produce corn sufficient for the consumption of the inhabitants. Rye, barley, oats, potatoes, and flax are grown. The climate is unfavourable to horticulture. The forests, of which a very large proportion belongs to the crown, consist of the pine, the larch, the birch, and the lime-tree; in the south-eastern part the oak, the ash, the birch, and the elm are found, and in the districts of Tcherdyne and Werkhotourie, the cedar. These forests, in which, as in other provinces, enormous waste is committed, supply fuel for smelting the produce of the mines. Game and fur-bearing animals abound. The government of Perm owes its riches to its minerals, and the working of the mines employs the greater part of the inhabitants. They produce iron, copper, platinum, a little lead, gold, silver, salt, marble, jasper, agates, amethysts, loadstone, and some diamonds. Of late years they have yielded on an average 250 poods (pood = 36 lbs.) of gold and 100 poods of platinum. The richest gold-mines are those of Beresoff. The crown possesses twenty-five forge-smelting-houses, in which 33,000 masters and workmen are employed; private individuals have 99 smelting-houses for iron and 35 for copper. The mines of the Ural mountains yield annually about 300 poods of gold, 200,000 poods of copper, and 5,500,000 poods of iron. The greater part of these products belongs to the government of Perm, which also produces about seven million poods of salt annually.

The number of domestic animals is, in round numbers, about 580,000 horses, which are necessary for the service of the mines and the carriage of their produce; 65[illegible] horned cattle; 680,000 sheep; 390,000 swine; and [illegible] goats. The Baschkirs breed a great quantity of bees: formerly they had camels, but the race appears to be extinct. The Woguls, in the north, have a few reindeer.

Three-fourths of the inhabitants are Russians. The remainder are Permians, descended from the antient inhabitants of the country between the Ural mountains and the White Sea, and various Tartar races. All the inhabitants profess Christianity, with the exception of about 3[illegible] Tartars and Baschkirs of both sexes, who are Mohammedans, and a very few Tcheremisses and Woguls, who are still pagans.

There are some manufactures of cloth, leather, soap, candles, &c. Trade is very brisk, partly in consequence of the facility for water-carriage on the Kama and its tributaries, and partly owing to the thirty-nine annual fairs, eighteen of which are held in the towns, the most considerable being that of Irbit. With respect to education, Perm is under the university of Kasan, but education is confined to a very small portion of the inhabitants. According to Schmidtlin, whose book was published in 1835, there were, by the latest accounts that he could procure, which seem to have been of 1832, 62 schools, with 123 teachers and [illegible] pupils, which was one scholar out of 294 inhabitants; taking the population at that time, as he does, at about 1,200,000.

The town of PERM, the capital of the government, is a modern town, having been built in obedience to a ukase of Catherine II., issued in 1780. It is situated in 5[illegible] N. lat. and 56° 30′ E. long., at the conflux of the Iagousc[illegible] and the Kama. The streets are broad and regular, the houses almost all of wood, and the town is surrounded by a boulevard planted with trees. There are only two churches, so that it does not look like a Russian town. It is described by Mr. Engelhardt as a dull town, destitute of resources. The population is about 10,000. It is a bishop's see. Ekaterinenburg, with 12,000 inhabitants, is a place of much greater importance. [EKATERINENBURG.] Kungar, at the junction of the Iron and the Sylwa, a fortified town with 6000 inhabitants, has manufactures of leather and soap. Within a mile of the town, on the banks of the Sylwa, there are caverns in the rock, which appear to have been formerly inhabited by many thousand families. Solimansk, at the conflux of the Uffolka and the Kama, has 5000 inhabitants, five churches, and two convents. The salt-works at Solimansk belonging to the crown yield 1,300,000 poods annually; and those belonging to the Stroganoff family, four millions and a half of poods. Owing to the road to Siberia passing through this town, it has a considerable trade. There is a botanic garden, in which the principal plants of Russia and Siberia are cultivated. Nischnei-Newiansk has 12,000 inhabitants, who have considerable manufactures of lacquered or japanned ware. Irbit, or Irbizk, on the Neiwa, near its confluence with the Irbit, has 3500 inhabitants, and is celebrated for its annual fair, which is frequented by Bokharian, Persian, Armenian, Greek, &c. merchants. The value of the goods brought to the fair is about 35 millions of rubles, and is annually increasing. In 1836 the value of Russian goods was 30,387,830 rubles; of European, 395,800; of Chinese, 3,258,420; of Bokharian, 745,000; horses, 15,000: total, 34,800,000 rubles. Irbit is a neat, regularly built, and rapidly improving town.

PERMUTATIONS. [COMBINATIONS.]

PERNA. [MALLEACEA, vol. xiv., p. 385.]

PERNAMBUCO, a seaport in Brazil, situated in 8° S. lat. and 34° 50′ W. long. It consists of two towns, Recife and Ollinda, nearly three miles distant from one another. The Citade do Recife consists of three different parts, called Bairro do Recife, Bairro de São Antonio, and Bairro de Boa Vista. The Bairro do Recife is built on the south-eastern extremity of a low and sandy peninsula formed by the mouths of two small rivers, the Capibaribe on the south, and the Biberibe on the north; being contiguous to the harbour, it is the seat of the commerce. The harbour is formed by a recife, or chain of reefs, which extends along the whole coast of the projecting portion of Brazil, from Bahia on the south to Cape S. Roque on the north. Opposite Recife this reef runs parallel to the shores and about 200 yards from it, and resembles a large flat wall, elevated about six feet above low-water mark. This reef, which is perpendicular on the land-side, and slopes gradually towards the open sea, is interrupted by a break north of the northern extremity of Recife. This break, which is rather narrow, is the entrance of the port. Inside the reef the water is not agitated by the swell of the sea, and vessels are completely sheltered. The port itself is divided into two parts by a shoal. The southern part, called Porto do Mosqueiro, is only used by vessels not drawing more than 14 feet of water. Larger vessels remain in the northern harbour, opposite the entrance, which is called Pouço, and is sometimes exposed to a swell from the sea, especially during spring-tides, which rise five feet. The town is indifferently built, and the streets are narrow, but generally paved. The Rua das Cruzes, which is the only wide street, contains many substantial houses. The storehouses are extensive. A stone bridge leads from Recife to the Bairro de S. Antonio, which occupies the western part of an island formed by two branches of the Capibaribe. Its streets are better than those of the Recife, and have raised foot-ways laid with bricks; but they are not paved, and are generally sandy. There is a small square, surrounded with neat houses, and forming a kind of bazaar, consisting solely of shops, in which a variety of articles are sold. The treasury and the governor's palace are situated in S. Antonio. This part of the town is united to the Bairro de Boa Vista by a bridge chiefly of wood. It is built with great irregularity on an undulating plain, and has lately increased more than the other parts of Recife, many neat country-houses having been erected in the plain, which are surrounded by groves of cocoa-nut trees. As the tide enters the rivers some distance above the places where the three towns are built, the water is not fit for drinking. A reservoir has accordingly been constructed near Ollinda, by forming a sort of barrier, denominated a varadoiro, across the river Biberibe, which impedes the farther advance of the tide, and accumulates the fresh-water above. This barrier, which also serves as a bridge or passage over the river to Ollinda, is in part covered by a handsome archway, below which the water passes, partly through circular spouts, and partly through larger and square channels. From this place the water is carried in canoes to Recife. Recife has a college, with three professors of Latin, one of philosophy, and another of eloquence and poetry.

Ollinda is beautifully situated upon a cluster of eminences which are connected with the mountains farther west. It was once a considerable town, but has been on the decline for the last two centuries. It is rather well built, contains many convents, an episcopal palace, finely situated; a botanical garden of trees and exotic plants, mostly brought from Asia; and a college, with professors of Greek, Latin, French, geography, rhetoric, universal and ecclesiastical history, philosophy, dogmatic and moral theology, and drawing. Ollinda contains about 1200 houses and 8000 inhabitants, and is inhabited by rich individuals and men of letters. The Citade do Recife contains more than 60,000 inhabitants, chiefly occupied in its extensive commerce. S. Antonio is by far the most populous of the three towns, and most of its inhabitants are mechanics. The exports of Pernambuco, in 1828, consisted of 1,513,120 arobas of sugar, 35,400 bales of cotton, 53,000 hides, 200 puncheons of rum, and some other articles to a less amount, as leather, drugs, Brazil wood, &c. In the same year were imported 40,000 casks of cod, mostly from England; 24,000 casks of flour, from the United States and Germany; 10,000 pipes of wine; 300 pipes of brandy; 400 pipes of olive-oil; 600 pipes of vinegar; great quantities of British manufactured goods, especially of cotton; silk goods from France and China; and several other articles of less amount. The number of vessels which annually depart from this port to Europe and North America is about 200.

The town of Pernambuco was taken by the Dutch in 1630, and remained in their possession to 1654. The Dutch did more for its public works in that short period than has been done ever since.

(Henderson's *History of Brazil;* Spix and Martius *Reise in Brasilien.*)

PERNAU. [LIVONIA.]

PERNIS. [FALCONIDÆ, vol. x., p. 184.]

PERODICTICUS, Mr. Bennett's name for a *Lemuridous* species, probably, in his opinion, the animal noticed and imperfectly represented by Bosman under the name of *Potto.*

Generic Character.—Face somewhat lengthened. *Limbs* subequal. *Tail* moderate. *Index* very short, the ungueal phalanx alone exserted.

Dental Formula:—Incisors $\frac{4}{6}$; Canines $\frac{1-1}{1-1}$; Molars $\frac{4-4}{3-3}$?

Mr. Bennett further describes the upper incisors as being subequal, and the lower as slender and sloping (*declives*); the canines as conic, compressed, with the anterior and posterior margins acute; the first upper molar as smallest, the second larger, and both conic; the third as acutely tuberculate, the tubercles being two externally and one internally; the fourth like the preceding, its internal tubercle rather larger than the rest (absent in the young specimen); the lower molars are described as consisting of two, conic and equal, and a third externally acutely bituberculated, and having one internal tubercle; the rest absent.

Example, *Perodictus Geoffroyi*, Bennett.

Description.—Colour chestnut, paler below, with a few ash-coloured hairs interspersed; fleece woolly.

Locality.—Sierra Leone.

This, with another animal (*Aulacodus Swinderianus*, Temm.), was presented to the Zoological Society of London by Mr. Boyle, colonial surgeon, Sierra Leone. The brine into which they had been put upon their deaths, which occurred upon the homeward passage, unfortunately proved too weak for their perfect preservation, but they were, on their arrival, transferred to strong spirit, with the view of preserving them as much as possible.

Mr. Bennett gives the following as the synonyms of this highly interesting animal: *Potto*, Bosman (*Guin.*, ii. 35, No. 4?); *Lemur Potto*, Gmel. (Linn., *Syst. Nat.*, 42?); *Nycticebus Potto*, Geoff. (*Ann. Mus.*, xix., 165?); *Galago Guineensis* (Desm., *Mamm.*, 104, No. 127?); and describes the head as rounded with a projecting muzzle, the nostrils lateral, small, sinuous, with an intermediate groove extending to the upper lip, the tongue rough with minute papillæ, rather large, thin, and rounded at the tip, and furnished beneath with a tongue-like appendage, which is shorter than the tongue itself, and terminates in about six rather long lanceolate processes, forming a pectinated tip. The eyes are small, round, somewhat lateral and oblique; the ears moderate, open, and slightly hairy both within and without; the body rather slender, and the fingers moderately long. The index on the forehands is excessively short, the first phalanx being concealed, and the ungueal phalanx (the only phalanx free) being barely large enough to support a rounded nail, which did not exist on the specimen, but of which there was an apparent *cicatrix*. Nails of all the other anterior fingers flat and rounded; those of the hinder hands similar, except that of the fore-finger, which, as in the *Lemurs* generally, is long, subulate, and curved. Tail of moderate length, covered with hairs resembling those of the body. Hairs generally long, soft, and woolly, each of them mouse-coloured at the base, rufous in the middle, and paler at the tip; some few tipped with white. This arrangement produces on the upper surface and on the outside of the limbs a chestnut hue, slightly mixed with grey; the under surface is paler. Muzzle and chin almost naked, and having only a few scattered whitish hairs. Length of the head two inches and two-tenths; of the body six inches; of the tail one inch and six-tenths, or, including the hairs, two inches and three-tenths. Breadth of the head, in front of the ears, one inch and four-tenths; distance between the eyes four-tenths; from the anterior angle of the eye to the end of the nose seven-tenths; from the eye to the ear fifteen-twentieths; length of ears behind, five, of their aperture eight, breadth five-tenths. Elaborate measurements of the anterior and posterior limbs are given by the author, to which we refer the reader.

Habits.—Mr. Boyle describes the animal as slothful and retiring, seldom making its appearance except in the night-time, when it feeds upon vegetables, chiefly, he believes, the *Cassada*. The colonists know it as the *Bush Dog*.

Mr. Bennett remarks that this genus is readily distinguishable from the other *Lemuridæ* by the comparative length of the tail. In this, he observes, in the moderate elongation of the face, in the moderate size of the ears, in the equality of the limbs, and especially in the extreme shortness of the index of the anterior hands, reside its essential characters. The latter character is regarded by Mr. Bennett as especially important, and he considers it as indicating its typical station in a family, all of which are distinguished from the neighbouring groups by a variation in the form of the index or of its appendages. 'In the *Lemuridæ* generally,' says Mr. Bennett, in conclusion, 'the nail of the index of the hinder hands is elongated and claw-shaped, and unlike those of the other fingers, which are flat, as in the monkeys. This is frequently accompanied by an abbreviation of the index of the fore-hands, which becomes in *Loris*, Geoff., very considerable, and is in *Perodicticus* carried to its *maximum*, that organ being here almost obsolete.' (*Zool. Proc.*, 1831.) [LEMURIDÆ; OTOLICNUS.]

PERO'NIA. [CYCLOBRANCHIATA, vol. viii., p. 249; LIMAX, vol. xiii., p. 486.]

PERONNE. [SOMME.]

PEROUSE, JEAN FRANÇOIS GALAUP DE LA, a distinguished French seaman and navigator of the last century, was born at Alby in the department of Tarn, in 1741. He entered early into the French navy, and was appointed midshipman in 1756. He distinguished himself in the battle of Belleisle (1759), and was taken prisoner. After the peace of 1762 he returned to his native country. In 1773 he visited the East Indies, where he served to 1777. In the war from 1778 to 1783 he distinguished himself on several occasions, and in the beginning of 1782 he was sent with three vessels to take possession of the establishments of the Hudson's Bay Company, on the shores of the bay from which the company derives its name. He took Fort York on the 24th of August, without resistance, as there was no garrison, and after having ordered the fort to be destroyed, he re-embarked and abandoned it. Having been informed that several Englishmen had escaped into the woods, and fearing that they would perish with hunger or fall into the hands of the savages, he left some provisions and arms, an act of humanity which was acknowledged by the English with gratitude. At Fort York he found the manuscript of Hearne's 'Journey to the Coppermine River,' which he was inclined to take to France, but Hearne declaring that it was his private property, he restored it to him, on the express condition that it should be printed on his return to England. The promise was made, but only performed thirteen years after.

After the re-establishment of peace (1783), the French government wishing to rival the English in making discoveries in the Pacific, La Perouse was appointed commander of a squadron, consisting of two frigates, the Boussole and Astrolabe. He sailed from Brest on the 1st of August, 1785, and went round Cape Horn. After doubling Cape Horn, he sailed to 60° N. lat., and then coasted along the western coast of North America to Monterey in Upper California, which coast had previously been examined by Cook and Vancouver. From Monterey he went to Canton, and thence along the eastern coast of Asia to Avatsha in Kamtchatka. This is the most important part of his voyage, as he surveyed a coast which previously was very imperfectly known. From Avatsha he sent one of his officers, Lessep, with an account of his voyage, to Paris by land. After leaving Avatsha he sailed to the Navigators' Islands, where the Astrolabe lost her captain and eleven of the crew, who were killed by the natives. After touching at the Friendly Islands, he sailed to Botany Bay, where he found that Governor Phillip had arrived for the purpose of founding the first British colony in Australia. From this place he sent to Europe the continuation of the account of his voyage, and after leaving Botany Bay he was never heard of. It was supposed that his vessels were wrecked, and the French [illegible] sent several ships to ascertain his fate. It was finally ascertained that his vessels had been wrecked on one of the islands of Santa Cruz, also called Queen Charlotte Islands. This island is called by the English Wanicoro, or Vanicolo, and by the French Isle de Recherche. (La Perouse, *Voyage autour du Monde*.)

PERPENDICULAR (overhanging), the name given in geometry to a line or plane which meets another line or plane without inclining to one side or the other, so as to appear to proceed directly towards the other line or plane. The subject will be considered in a mathematical point of view under RIGHT ANGLE.

PERPETUAL MOTION. [MOTION.]

PERPETUATION OF TESTIMONY. A party who has an interest in property, but not such an interest as enables him immediately to prosecute his claim, or a party who is in possession of property and fears that his right may at some future time be disputed, is entitled to examine witnesses in order to preserve that testimony, which may be lost by the death of such witnesses before he can prosecute his claim, or before he is called on to defend his right. This is effected by such party filing a bill in equity against such persons as are interested in disputing his claim, in which bill he prays that the testimony of his witnesses may be perpetuated. This is the only relief that the bill prays. If the prayer of the bill is granted, a commission issues to examine the witnesses, whose depositions are taken in the usual way in suits in equity. The depositions, when taken, are sealed up and retained in the custody of the court which grants the commission. When they are required to be used as evidence, they can be so used, by permission of the court, by the party who has filed his bill or those who claim under him, and they can be read by the direction of the court as evidence on a trial at law, if it is then proved that the witnesses are dead, or from any sufficient cause cannot attend. If the witnesses are living when the trial takes place, and can attend, they must be produced. A defendant to such a bill may join in the commission, and may examine witnesses under the commission, and he is entitled to use their depositions as evidence in his favour at a future trial. (1 Mer., [illegible])

A bill to perpetuate testimony may be filed by any person who has a vested interest, however small, in that thing to which he lays claim. The parties, defendants to such [illegible] are those who have some adverse interest to the plaintiff. In order that the testimony which the plaintiff seeks to perpetuate may be good evidence for him at the trial, he must make all proper parties defendants to his bill, who may be generally described to be such persons as would be necessary parties to a bill in equity by the plaintiff to enforce [illegible] maintain his rights, if a court of equity could take [illegible]zance of the matter, and the question between the [illegible] and such parties could then be raised. The evidence [illegible] taken may be read at the hearing of a cause, or at a trial at common law against all such parties to the bill, and [illegible] who claim through or under them.

A bill to perpetuate testimony and a bill to examine witnesses De bene esse are sometimes confounded. The [illegible] to perpetuate testimony has been already described. [illegible] bill to examine witnesses De bene esse is only filed when an action has been brought, and the plaintiff is afraid that his witnesses, owing to age or infirmity, may die before the [illegible] may take place, or he has only one witness to an important fact. Both these are in a sense bills to *preserve* or *perpetuate* testimony; but the one is filed before the matter which may be in dispute can be the subject of judicial investigation, and the other is filed when an action has been already brought. As courts of law can now examine witnesses on oath upon interrogatories in an action depending in those courts (1 Wm. IV., c. 22), an application to a court of equity for such purpose is no longer necessary.

Witnesses may be examined *De bene esse* in a suit in equity, when it is necessary to secure their evidence at a period of the suit prior to the regular time for examination of witnesses in the cause. But this is only a provisional examination, and the evidence can only be used in case the witnesses cannot be examined at the proper time for the examination of witnesses in the cause. [DEPOSITION.]

PERPETUITY, the technical term for a yearly payment or annuity which is to continue for ever; also called a perpetual annuity.

PERPETUITY. (Law.) [SETTLEMENT.]

PERPIGNAN, a town in France, capital of the department of Pyrénées Orientales, at the junction of the little river Basse, or Canals, with the Tet, 424 miles in a direct line south of Paris, or 564 miles by the road through Orléans, Limoges, Cahors, Montauban, Toulouse, and Narbonne.

Perpignan was anciently a mere hamlet, called Coreb, which gradually increased and became the capital of Roussillon. Having passed with the rest of that province into the hands of the kings of Aragon, it became in 1349 the seat of a university founded by Pedro, one of those kings. In 1475 it was besieged and taken by famine, after a vigorous resistance, by Louis XI. of France. Having been restored to Spain, it was again taken in 1642 by Louis XIII., and was included in the cession of Roussillon to the French. In the wars which followed the French revolution, the Spaniards were defeated under the walls of this town by the French, A.D. 1793. In 1604 Perpignan was made by transfer the seat of a bishopric.

The town is situated partly on the slope of a hill, and partly in the plain at its foot, on the right or south bank of the Tet, over which are two bridges. It is fortified by an old wall and by bastions and outworks of later construction. A strong citadel commands the town on the south side. The fortifications were all thoroughly repaired in 1823. There are barracks for 3000 men, built by Louis XIV., and occupying one side of the parade. Perpignan is divided into the old and new towns. The streets, with the exception of one or two, are narrow and dark, and the houses are ill built. The cathedral is the most remarkable building, and, but for the want of a porch, would be a fine structure. There are three or four other churches and a convent. The town-hall, the court-house, the mint, and the theatre, are all inferior structures.

The population in 1831 was 16,272 for the town, or 17,114 for the whole commune; in 1836 it was 17,618 for the commune. The manufactures are woollen cloth and woollen stuffs, lace, leather, soap, and sails. Cork-cutting is carried on. The trade of the town is facilitated by its situation on the only high road from France into Spain at this end of the Pyrenees, and by its vicinity to the Mediterranean, from which it is distant about six miles: the chief articles of commerce are the red wines of Rivesaltes, the liqueur wines of Collioure and other places, and the stout red wines of Banyuls, all produced in the department; brandy, oil, silk, wool, iron, and cork. There are six yearly fairs. There are at Perpignan a seminary for the priesthood; a high-school, with a cabinet of natural history attached to it; a museum, a library of 15,000 volumes, a school for linear drawing and architecture, and a school of music; an agricultural society, a botanic garden, a departmental nursery, a government sheep-fold for merinos, and a government stud; two hospitals, one of them military; a theatre and public baths; a subordinate court of justice, a commercial court (*tribunal de commerce*), and several government offices, administrative and fiscal.

The diocese comprehends the department; the bishop is a suffragan of the archbishop of Alby. The arrondissement has an area of 331 square miles, and comprehends seven cantons or districts, each under a a justice of the peace, and 81 communes. The population in 1831, was 72,814; in 1836, 76,224.

PERRAULT, CLAUDE, born at Paris in 1613, has earned a memorable name in the history of art as the designer of one of the finest monuments of modern architecture. He was the son of an advocate, and was brought up to the medical profession, but extended his studies to other branches of science, particularly mathematics and architecture. His attention became more especially directed to architecture on being engaged by Colbert to undertake a translation of VITRUVIUS, the first edition of which appeared in 1673, in a folio volume, with plates after his own drawings. If he did not always comprehend the meaning of that exceedingly obscure writer, he had in the meanwhile given indisputable proof of his practical ability and superior taste in architecture in the east front and colonnades of the Louvre, in regard to which edifice, Bernini (invited to Paris in 1665) and other eminent artists had been consulted. It appears to have been at the instance of his brother Charles that Perrault entered into the competition, in which he bore off the prize from his rivals; and his superiority on this occasion has by one of his biographers been attributed to his being unshackled by professional prejudices and habits. For some remarks on this deservedly celebrated façade, we refer to PARIS, p. 228; and shall here merely add, that notwithstanding its defects, which would now be avoided by one of far inferior talent, it is certainly a chef-d'œuvre of art for the same age which had admired a Maderno and a Borromini.

Perrault's other chief works are the Observatory (not particularly remarkable in point of design), and the Grotto, &c., at Versailles. The monument which, after the Louvre, would have best maintained his fame, the grand triumphal arch at the entrance of the Faubourg St. Antoine, was never executed, notwithstanding the foundations were built, and a temporary plaster model of the whole was erected. Besides his translation of Vitruvius, an enlarged edition of which appeared in 1684, he published an abridgement of it, 1674; a work 'On the Five Orders,' fol., 1683; 'Essais de Physique,' 4 vols. 4to., 1680; and a work on natural history; to which may be added a posthumous one (1700), giving an account of several machines of his invention. He died at Paris, Oct. 9th, 1688.

PERRAULT, CHARLES, brother to the preceding, born Jan. 12th, 1628, possessed also some talent for architecture, which procured for him the appointment of 'premier commis des bâtimens du roi.' He is now chiefly known as the author of the 'Parallèle des Anciens et Modernes,' Paris, 1690, wherein he exalts the latter at the expense of the former; and whatever may be thought of his judgment, he must be allowed to have shown no little courage when he ventured to express his preference of such writers as Scudéri and Chapelain to Homer. Such an extravagant opinion was hardly worth serious refutation, yet it was formally opposed by Boileau, in his 'Reflexions on Longinus,' intended as an answer to the 'Parallèle,' and this literary squabble was prolonged for some time. Of Perrault's work entitled 'Les Hommes Illustres qui ont paru en France pendant ce Siècle,' fol., the first volume appeared in 1696, the second in 1701. A collection of his miscellaneous pieces in verse and prose appeared at Paris in 1676, previously to which he had produced some other poems, which have long since been forgotten. One of his most interesting literary productions is his own Mémoires, first published at Avignon, in 1759. He died in 1703.

PERRAULT D'ARMACOURT, son of Charles Perrault, was also a writer, and is still remembered by his 'Contes des Fées,' which contain the nursery stories of Cinderella, &c., and may be considered as a classical work in that branch of literature.

PERROT, N. [ABLANCOURT.]

PERSE'A GRATI'SSIMA is the Avocado Pear of the West Indies, and receives its name in consequence of the resemblance in form between its fruit and that of a European pear. In reality it is a Lauraceous plant, allied to the Sweet Bay of our climate. The tree is about the size of an apple-tree; the leaves are oblong, veiny, and the flowers small, and of a greenish-yellow colour. The fruit is the size of a large pear, and is regarded as one of the best produced in the West India Islands. In the inside it is yellow, and contains a kernel enclosed in a soft rind. In taste it is said to resemble the peach, but to be much more agreeable, though not so sweet. It is sometimes eaten with pepper and salt, but more frequently with a little sugar and lime-juice. Three varieties are mentioned, the red, the purple, and the green.

Persea gratissima.

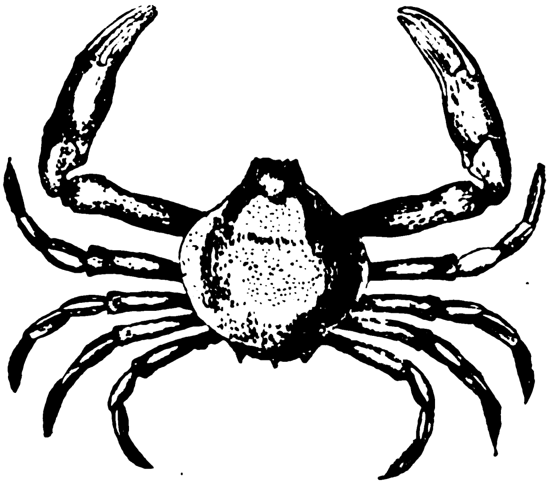
PERSE'PHONA, Dr. Leach's name for a genus of brachyurous crustaceans, placed by M. Milne Edwards among the tribe of *Leucosians*. [Oxystomes, vol. xvii., p. 110.)

Generic Character.—External and internal stems of the *exterior jaw-feet* gradually lessening from their base, the external stem being very obtuse at the extremity. *Carapace* rounded, depressed, and dilated on each side. *Front* rather advanced. Great joint of the abdomen of the male composed of three pieces soldered together. First pair of feet much stouter than the others, which have their two last joints compressed.

Example, *Persephona Latreillii.*

Description.—Anterior part of the shell gradually and obtusely dilated, covered with granulations; three equal recurved spines at its posterior part; arms tuberculous. Length two inches and a half.

Locality, unknown.



Persephona Latreillii.

PERSE'POLIS (Περσέπολις) is mentioned by Greek writers after the time of Alexander as the capital of Persia. The name however does not occur in Herodotus, Ctesias, Xenophon, or Nehemiah, who were well acquainted with the other principal cities of the Persian empire, and make frequent mention of Susa, Babylon, and Ecbatana. Their silence may be accounted for by the fact that Persepolis never appears to have been a place of residence for the Persian kings, though we must conclude, from the account of Arrian and other writers, that it was from the most antient times regarded as the capital of the empire. The kings of Persia appear to have been buried here or at Pasargadæ. There was at Persepolis a magnificent palace, which at the time of Alexander was full of immense treasures, which had accumulated there from the time of Cyrus. (Diod. Sic., xvii., 71; Strabo, xv., p. 729.) We know scarcely anything of the history of Persepolis. The palace of the Persian kings and a part of the city were burnt by Alexander (Arrian, iii. 18; Curt. v. 7; Strabo, xv., p. 729; Diod. Sic., xvii. 70); but it still continued to be a place of considerable importance after his time (Diod. Sic., xix. 22). We read of an attempt by Antiochus Epiphanes to plunder it, which did not succeed. (2 *Mac.*, ix. 1, 2.)

There has been considerable dispute respecting the Persian name of Persepolis. Oriental historians say that it was Istekhar or Estekhar (D'Herbelot, *Bibliothèque Orientale*), and many modern writers suppose that Pasargadæ and Persepolis are only different names for the same place, and that the latter word is the Greek translation of the former. There are however strong reasons for believing that they are distinct places. [Pasargadæ.]

Persepolis was situated in an extensive plain, near the union of the Araxes (*Bendemir*) and Cyrus (*Kur*). The situation appears to have been very healthy and favourable to longevity. Mr. Rich, when he visited the spot, heard of several persons who had attained the age of a hundred. (*Narrative of a Journey to Babylon and Persepolis*, p. [illegible].) The ruins of Persepolis, which are usually called by the inhabitants Tchil-Minar, that is, 'the forty pillars,' are described at great length in Sir R. K. Porter's 'Travels,' vol. i., p. 576, fol. [Persepolitan Architecture; Arrow-headed Characters.]

PERSEPOLITAN ARCHITECTURE. The remains of buildings on the site of Persepolis, or in its vicinity, are few and so imperfect as to render it impossible to judge of the style of architecture beyond a few particulars. It seems to have had much in common with that of Egypt, and yet to have differed materially from it in various respects. Of tombs and sepulchral chambers hewn out of the perpendicular face of rocks, there are several specimens at Naksh-i-Rustam; yet these bear little similarity to the subterranean or excavated catacombs of Egypt, which are generally of very great extent, and consist of one or more passages leading to different apartments; whereas these antient Persian excavations are very shallow, and consist chiefly of an architectural frontispiece or portico richly adorned with sculpture and other decorations. Such are those at Naksh-i-Rustam; also the tomb of Darius, the son of Hystaspes, at the foot of Mount Rachmed, near the river Bendemir, the antient Araxes. This monument has a portico of four columns, whose capitals have figures of the foreparts of animals projecting from their sides. There are also two rows of sculpture above the portico.

The present inhabitants call the remains of Persepolis itself Tak-Jamschid, or the residence of Jamschid (supposed by them to have been its founder); and by the Mohammedans, Tchil-Minar, or the Forty Columns, of which number however scarcely half are now remaining. These columns, and some other parts of the palace to which they belonged, stand upon an eminence or terrace formed by levelling the surface of a marble rock, and which extends upwards of 400 yards from north to south, and about [illegible] from east to west. Though it may be described as a parallelogram in its general shape, this platform is not perfectly regular in plan, being indented by projections and recesses which follow the sinuosities of the superficies of the rock itself; neither is it one uniform level throughout, those parts which were covered with buildings being somewhat elevated above the rest. The height above the plain from which the rock rises varies considerably in different places, in some being not more than 14 feet, and in others 40. On every side except the east, where it adjoins a hill forming a sort of screen or background to it, the platform is enclosed by walls or parapets constructed of large blocks of masonry; and that opposite the loftier ground to the east, the western (1425 feet in extent), may be considered the principal front, and accordingly here we find the entrance, not however in the centre, but about midway between that and the north-west angle. The ground is here somewhat more than 20 feet below the terrace, owing to which there is a considerable ascent, which is not formed by wide flights of steps in a direct line leading to the entrance, but by two [illegible], ramps or flights in contrary directions, which return to the upper landing-place. Facing this latter, but at a little distance from it, is a *propylon*, or lofty mass with a doorway, similar to those in Egyptian architecture.

little beyond it a second entrance of the same kind. Like the Egyptian, these propyla diminish upwards, and are crowned by a cavetto, or hollow cornice: they are also adorned with fanciful colossal figures of animals, partly in low and partly in high relief, sculptured on their sides, and among these monsters are some representing winged horses with human heads. It is probable that these propyla led into some enclosure serving as the chief or entrance court of the palace; but that cannot now be determined, nor in what manner the principal mass of building now remaining could have been made to display itself conspicuously from such an enclosure; because, instead of being on the east side facing the entrance, it lies on the south or right hand of the entrance, and in such manner as to extend more westward, consequently it would have been necessary to turn back to it in that direction from any court beyond the propyla. Neither is it certain whether this edifice was any part of the palace itself or actual residence, or only a temple belonging to it. The plan would seem to favour the latter supposition, because, from what can now be made out from it, this structure contains within, not a spacious hall suited for entertainments, but one filled with lines of columns in every direction (as is evident from the position of those now remaining), so as to form a number of aisles intersecting each other. Such a grove-like arrangement of numerous pillars is altogether unlike anything in Grecian architecture, and more in accordance with that of the Arabians, some of whose buildings, the mosque at Cordova for instance, are similarly filled with lines of columns. A similar dense disposition of pillars prevailed also among the Egyptians; and for an example of it among the latter people, we refer to the plan of the temple at Edfu [EGYPTIAN ARCHITECTURE, p. 316], where both the pronaos and vestibule are in the same manner *polystylar*, or filled with columns, although they occupy a smaller space, and are consequently not so numerous.

The columns at Persepolis are of grey marble, 5 feet 9 inches in diameter, and about 72 feet, or nearly thirteen diameters in height; therefore of very slender proportions, and so far very different from Egyptian columns. Neither do they otherwise resemble them, except in their dissimilarity from the Grecian orders and in the capriciousness of their decoration. Of some of these columns the shafts are ornamented with a kind of zigzag or vandyke pattern, after the manner of the fragment found near the Treasury of Atreus at Mycenæ; while others are fluted, but the channels are exceedingly narrow, being forty, or double the number of those of a Doric column. The bases and capitals are still more singular, both of them being very deep and of fanciful shape and outline. In fact the capitals are composed of so many divisions that the lowermost of them seem to belong as much to the upper part of the shaft as to the capital itself; or if all are included as parts of that member of the column, it must be reckoned at one-fifth of the entire height. Among their fanciful ornaments occur small scrolls, which some have thought to bear a resemblance to Ionic volutes, but it certainly requires a very strong imagination to detect the similarity, although a tolerable resemblance of an Italian Ionic capital may be seen in the drawing of a Persepolitan one by holding the latter sideways, so that the scrolls, which are there one above another, are brought into a horizontal direction. Other Persepolitan capitals have figures of unicorns or other animals projecting from them laterally beneath the epistylium.

Besides the building above mentioned, there are traces of various others behind it, on the south side: among the rest, the remains of two *polystylar* halls; but even including these, the plan would have been exceedingly limited and inadequate to the accommodation required for the court of a prince and a numerous retinue, unless the buildings originally extended themselves much beyond the actual ruins, and consisted of several stories. Eastward of the first described large hall is another very spacious one, perfectly square in plan, and with two entrances on each of its four sides, but without columns; it is therefore questionable whether it was not a court, or was else originally divided into separate rooms.

Even were these ruins in a more perfect state, they would not, as a solitary example, go very far towards elucidating the architectural style of the antient Persians. Some points of resemblance between it and Egyptian architecture have already been pointed out, namely, lofty square-beaded gateways, or propyla, terrace-like platforms, and polystylar apartments, in which the columns are arranged phalanx-wise, to which may be added the mode of decorating doors, and the practice of covering the entire surface of walls with figures or inscriptions, as is the case with the fronts of the terraces at Persepolis. Even the sculpture itself shows the state of that art to have been nearly the same as among the Egyptians, the drawing of the figures being rude and stiff, and they being nearly all represented in profile, without any attempt at grouping, while the clumsy expedient is adopted of indicating a king or chief personage by making such figure larger than the rest. It is not likely that all these circumstances of resemblance were merely casual coincidences; but neither is it possible to offer any hypothesis that would account satisfactorily for many striking points of disparity, particularly as regards both the proportions and decoration of columns, which, being the principal features in every style, would be those most likely to be copied, with more or less exactness, where any imitation was aimed at. Instead of this, the Persepolitan style appears to have been most licentious in regard to columns, and in this respect not only dissimilar from but greatly inferior in taste to the Egyptian. The sculptures of Persepolis, though of no value as works of art, serve to elucidate some passages in Greek and Roman-writers which relate to Persian affairs.

There are in the British Museum some specimens of Persian sculpture brought from Persepolis.

(Niebuhr, *Reisebeschreibung*, &c., ii. 121, &c., who has given a plan of the buildings and various drawings of the monuments and the reliefs; Ker Porter's *Travels*, vol. i., p. 576; Le Bruyn; Chardin; Morier; Hirt, *Baukunst*, &c.)

PERSEUS, son of Philip V., king of Macedonia, began at an early age to serve in his father's army, and distinguished himself by some successes against the barbarous nations which bordered on Macedonia. His younger brother Demetrius was carried away as a hostage by the consul Flamininius at the time of the peace between Rome and Philip, and after remaining several years at Rome, where he won the favour of the senate, was sent back to Macedonia. After a time he was again sent by his father to Rome, on a mission, in consequence of fresh disagreements which had sprung up between the two states. Demetrius succeeded in maintaining peace, but after his return to Macedonia, he was accused of ambitious designs, of aspiring to the crown, and of being in secret correspondence with Rome. Perseus, who was jealous of him, supported the charges, and Philip doomed his younger son to death, but not daring to have him openly executed, for fear of the Romans, he caused him to be poisoned. It is said that having discovered his innocence, his remorse and his indignation against Perseus hastened his death. Perseus ascended the throne in the year 179 B.C.

Perseus had been brought up by his father with sentiments of hatred against the Romans for the humiliation which they had inflicted upon Macedonia; however, he dissembled his feelings at the beginning of his reign, and confirmed the treaty existing between his father and the senate. But he soon began to prepare himself for war, and he endeavoured to form alliances with the states of Greece, and especially with the Achæans. The senate, hearing of this, sent legates to Macedonia to examine the state of affairs. Eumenes, king of Pergamus, a staunch ally of the Romans, was also closely watching the doings of Perseus, and he even went to Rome to report to the senate the hostile preparations of the Macedonians. On his return from Italy, as he was going to visit the temple of Delphi, an attempt was made upon his life by assassins hired by Perseus. Eumenes escaped, and the Roman senate declared Perseus to be the enemy of Rome, B.C. 172.

The consul P. Licinius was appointed to proceed with an army to Macedonia. At the same time commissioners were sent to Greece to exhort the allies of the Romans to join in the impending struggle against Perseus. Perseus had a conference with Q. Marcius, one of the commissioners, who granted him a truce, during which the king might send ambassadors to Rome to plead his cause. When the commissioners returned to Rome, they boasted of having deceived Perseus by holding out the hope of peace, in order to give time to Rome to prepare for war, whilst the delay could only be of disadvantage to the king, whose army was ready to take the field. Some of the older senators are said to have disapproved of this conduct as more deserving of the name of Punic than of Roman faith, but the majority of the senate, 'who cared more for what was advantageous than for what was honest,' supported the commissioners. (Livy, xlii. 47.) The legates of Perseus, after being heard by the senate, were dismissed without any satisfactory answer. Licinius, on arriving in Thessaly, 171 B.C., met the army of Perseus on the banks of the Peneus, but only partial engagements took place, in one of which the Roman cavalry was defeated, but in another it had the advantage, after which both armies went into winter-quarters. The following year, 170 B.C., seems to have been spent by both parties in preparations and desultory engagements. The consul Hostilius Mancinus made some attempts to enter Macedonia from Thessaly, but did not succeed. His legate Appius Claudius, being sent to Lychnidus in Illyria, attempted to surprise a town called Uscana, which was held by Perseus, but he was foiled, with the loss of most of his men. Meantime the exactions of the Roman prætors Lucretius and Hortensius had indisposed several of the cities of Greece against Rome, and produced a feeling favourable to Perseus. Those officers plundered Chalcis in Eubœa, a town allied to Rome, and allowed their soldiers to abuse the wives and children of the citizens. A citizen of Chalcis, who came to Rome to complain, said it had been found much safer to shut the gates against the Roman prætors than to receive them, for those who had shut their gates had escaped unhurt, whilst the allies of Rome were plundered. The people of Abdera, being required to furnish a heavy contingent of money and corn for the army, asked for a respite, but Hortensius entered the town, beheaded the principal citizens, and sold the rest as slaves. Envoys being sent to Rome by those unfortunate cities, the senate ordered the Abderites to be restored to liberty, and Lucretius, being summoned to Rome, was tried before the tribes, and fined a million of ases. (Livy, xliii. 4, 7, 8.) The Roman commissioners to the friendly states of Epirus, Ætolia, and Achæa, acted with less disregard to appearances, but with equal dishonesty. Those states, like all weak countries that submit to the dictates of a powerful stranger under the specious name of alliance, were divided into two parties: one willing to keep on friendly terms with Rome, but still mindful of their national honour and independence; the other servilely devoted to Rome. The leaders of the latter party sought the favour of the Roman consuls and prætors by accusing those whose views were not the same as their own, of being secret enemies of Rome. Some of the persons thus accused were summoned or in other words transported to Rome, to await the pleasure of the senate.

In the next year, 169 B.C., the new consul Q. Marcius came to take the command of the army against Perseus. He entered Macedonia unopposed, and took possession of the town of Dium, but finding it difficult to get supplies for his army, he withdrew to the frontiers of Thessaly, retaining possession however of the strong defile of Dium, which commanded the entrance of Macedonia on that side. On this occasion, Polybius, with others of his countrymen, being sent by the Achæans to offer their assistance to the consul, remained some time with the Roman army.

In the year 168 B.C., Paulus Æmilius was sent to command the army against Macedonia. He passed the mountains from Thessaly and advanced to Pydna, where he met Perseus with his army. The Romans found means to break through the Macedonian phalanx, and a frightful confusion and butchery followed, in which 20,000 Macedonians are said to have lost their lives. This single battle decided the fate of a powerful and antient kingdom; all Macedonia submitted to the Romans. Perseus fled, almost alone, without waiting for the end of the battle. He went first to Pella, the antient seat of the Macedonian kings, then to Amphipolis, and from thence to the island of Samothrace, whose asylum was considered inviolable. Thence he attempted to escape by sea to Thrace; but a Cretan master of a vessel, after having shipped part of his treasures, sailed away, leaving the king on the shore. The king's attendants having also forsaken him except one, Perseus, with his eldest son Philip, came out of the temple where he had taken refuge, and surrendered to the Romans. He was treated at first by Æmilius with considerate indulgence, but was obliged to parade the streets of Rome with his children, to grace the triumph of his conqueror. He was afterwards confined, by order of the senate, at Alba in the mountains of the Marsi, near the lake Fucinus, where he died in a few years. His son Philip also died at Alba. Another and a younger son is said to have become a scribe or writer to the muncipality of Alba.

PERSEUS (constellation). The mythological story of Perseus is well enough known: in the heavens the constellation is surrounded by Andromeda, Aries, Taurus, Auriga, Camelopardalus, and Cassiopeia. Of the two principal stars α and β (the latter of which is called Algol), the former is situated in the breast of the figure, the latter in the head of Medusa, which he carries in his left hand. The following are the principal stars;—

PERSHORE. [WORCESTERSHIRE.]

PERSIA, or PERSIS (Πέρσις), called in the Old Testament Paras (פָּרַס), and by the Arabic and Persian writers Fars, or Farsistan, is used in two significations: first, it is applied to the country originally inhabited by the Persians, and secondly, to the various countries in Asia included in the Persian empire founded by Cyrus, which extended from the Mediterranean to the Indus, and from the Black Sea and the Caspian, to the Persian Gulf and the Indian Ocean.

Persis proper was bounded on the north and north-west by Media, from which it was separated by the mountain range known to the antients under the name of Parachoathras (Ptolem., vi. 4; Strabo, xi. 522), on the south by the Persian Gulf, on the east by Carmania, and on the west by Susiana, from which it was separated by rugged and inaccessible mountains. (Strabo, xv. 728.) The country included within these limits is, according to Chardin's estimate, as large as France. The southern part of it near the sea-coast is a sandy plain, almost uninhabitable on account of the heat and the pestilential winds which blow from the desert of Carmania. (Plin., xii. 20; Strabo, xv. 727.) But at a short distance from the coast the ground rises, and the interior of the country towards the north is intersected by numerous mountain-ranges. The soil upon these mountains is very poor and barren, and though there are some fertile valleys among them, they are generally fit only for the residence of nomadic shepherds. This part of Persia was the original seat of the conquerors of Asia, where they were inured to hardship and privation. In the inner part of the country however there are many well watered and fertile plains, in the largest of which Persepolis is situated. (Strabo, xv. 7[illegible]; Ptolem., vi. 4.)

The Persians were divided into several herds or tribes, of which the principal were the Pasargadæ, Maraphii, and Maspii, and of these the Pasargadæ were the noblest, the chief clan of which, called the Achæmenidæ, the royal family of Persia belonged. (Herod., i. 125.) In addition to these tribes, Herodotus mentions the Panthialæi, Derusiæi, and Germanii, as agricultural tribes; and the Daï, Mardi, Dropici, and Sagartii, as nomadic tribes.

Herodotus says (vii. 61) that the Persians were originally called Artæi; which word probably contains the same root as Arii, the original name of the Medes (Herod., vii. 62), and *Arya*, the word by which the followers of the Brahmanic religion are designated in Sanscrit. The same root occurs in Aria and Ariana, from the latter of which the modern Persian name Iran seems to be derived. [ARIANA.]

The only places of importance in Persis were PERSEPOLIS and PASARGADÆ, of which an account is given in separate articles.

---

* This star is Flamsteed's 16, according to Mr. Baily.

PERSIA is called **IRAN** by the natives. The form and boundaries of the country to which this name is applied, are distinctly marked by nature. It lies between 25° and 40° N. lat. and 44° and 70° E. long., constituting an elevated table-land, surrounded by mountain-ranges, which mark the edges of the table-land, and separate it either from the sea or from the low countries which enclose it on the east, north, and west. On the south the table-land, or rather the ranges which enclose it, come close to the Persian Gulf and the Indian Sea. On the east of the table-land are the extensive plains which are watered by the river Sind, or Indus; and on the north the still more extensive plain which surrounds the lake of Aral, and extends to the eastern shores of the Caspian Sea. These desert plains are known to the natives by the name of Turan. A narrow and very low tract of land separates Iran from the Caspian Sea, and a somewhat more elevated and rather undulating plain divides it from the high range of Caucasus. Along the mountain-chains which form its western border, are the great plains drained by the Tigris and Euphrates. Thus the table-land of Iran is surrounded on all sides by lower countries, but it is connected with the mountain-ranges of Eastern Asia and Asia Minor by two chains. The chain which unites it with the Himalaya and Kuen-Luen mountains, in Eastern Asia, lies between 34° and 37° N. lat., and between 68° and 73° E. long., and is known by the name of Hindu Cush. At the most north-western extremity of Iran is Mount Ararat. From that high pinnacle a mountain-chain runs westward, and unites the table-land with the mountains of Asia Minor. This chain is called the Armenian Mountains.

The surface of the table-land of Iran, with the mountain-ranges enclosing it, according to a very rough estimate, may occupy an area of between 1,600,000 and 1,700,000 square miles, or about one-twelfth of the surface of Asia. The table-land is generally level, interspersed with low and rocky ridges of comparatively small extent, which are like islands or oases in the sandy sea which surrounds them. The level tracts, which occupy an immense space, and lie contiguous to one another, are either covered with loose sand, or sand impregnated with salt; but both these kinds of sand are nearly destitute of vegetation. Along the interior base of the mountain-ranges which extend along the edges of the table-land, there are large tracts the soil of which is generally fertile wherever there are means of irrigating the fields. However even in these tracts there are numerous ridges of rocks, which render cultivation always difficult, and frequently impossible.

This extensive country is at present divided into three independent states. The western half of it constitutes the present kingdom of Persia, or Iran, and the eastern is divided between the sovereigns of Afghanistan and Beloochistan. Of the two last-mentioned countries an account is found under their respective heads.

The modern kingdom of Persia extends between 25° and 40° N. lat., and from 44° to 62° 30′ E. long., and borders on the east on the kingdoms of Afghanistan and Beloochistan. The plains along the northern boundary are inhabited by several tribes of nomadic Turkomans as far west as the shores of the Caspian Sea, which constitutes the boundary-line on the north as far as 49° E. long., and washes it as far north as 38° 40′, where the line begins which separates Persia from Russia. This line commences on the shores of the Caspian Sea, at the mouth of the Astarah river, and runs along its course to its junction with the Kala Kishi; it then follows the course of this river to its source in the Talish Mountains. This range, which extends to the west of north, constitutes, as far as 39° N. lat., the boundary-line, which, farther north, passes to the Bala-rud river, and thence to the Aras river. The last-mentioned river separates Persia from Russia as far as the base of Mount Ararat, which is situated at the junction of the three empires of Russia, Turkey, and Persia. The western boundary line of Persia passes over the mountains of Kurdistan, which enclose the table-land of Iran on the west. North of 35°, the greater part of these mountain-ranges are subject to Turkey, the boundary-line between Turkey and Persia passing between the lakes of Van and Urumi or Urumiyeh; but south of that parallel, the whole of the mountain-system is now included within the territories of Persia, which, south of 33° N. lat., extend to the banks of the Tigris and Shat el Arab. According to a rough estimate, the surface of Persia is half a million of square miles, or considerably more than double the area of France. It includes the western half of the table-land of Iran, and also the low narrow tract which separates the table-land from the Caspian Sea, as well as a small portion of the low plain which lies to the west of the table-land on the banks of the Tigris.

Surface and Soil.—The following description of this country begins at the north-eastern angle, between 62° and 61° E. long., where the continuity of the mountain-range which constitutes the northern border of the table-land is interrupted by a wide break. Through this break the Heri-rud, or river of Herat, which rises within the table-land, finds its way to the wide plain of Turkestan, where it is joined on the right by the Thajen (Tedjen) and Murghab, and on the left by the Meshed river. East of this break the mountain-range runs uninterrupted, though with unequal elevation, eastward to the great mountain mass called the Hindu Cush. But west of the break, the mountains spread out into an elevated region, the general direction of which is south-east and north-west. In some places this mountain-region is 200 miles wide, but it grows much narrower between 57° and 54° E. long., where it approaches the shores of the Caspian Sea. This mountain-region, which descends rapidly towards the plains of Turkestan, but with a less rapid descent towards the south, is called the mountains of Khorasan, and is traversed by numerous ridges of hills, which run to the north of north-west on the northern edge of the region, but farther south, to the west of north-west, until the latter ridges decline to the west as they approach the Caspian Sea. The most elevated part of the region seems to be nearly in the middle, where the plains on which the ridges are based are perhaps near 3500 feet high, while the plains south of the mountain-region perhaps do not exceed 2500 feet in elevation. The ridges themselves are of moderate height, and seldom rise more than 1000 feet above their base. They are only covered with snow for one or two months in the year; and this circumstance, added to the want of rain and the general dryness of the atmosphere, renders them unfit for maintaining perpetual streams of water. The ridges themselves are rocky, and frequently steep, but of inconsiderable width, so that the longitudinal valleys which are enclosed by them are frequently 20 miles in width, and sometimes 100 miles long: such is the long valley which extends from Meshed on the south-east to Shirwan on the north-west. The declivities of the ridges are destitute of wood, except on the north side of the mountain region, called the Attak, where some trees occur, but they do not exhibit a vigorous growth. Though the rocky masses are generally without vegetation, some parts are covered with grass, and afford pasture during a great part of the year. The soil of the valleys, or rather plains, consists principally of gravel washed down from the rocky eminences, or of clay, which, when it has no moisture, is as barren as the rock itself. No kind of cultivation is possible without careful irrigation; but as water is scarce, only a very small portion of these plains can be cultivated. The numerous ruins of villages and towns in these plains show that a much greater portion of them was formerly under cultivation, and this change is chiefly if not entirely to be attributed to the continual predatory inroads of the wandering Turkomans, who inhabit the northern plains. The valleys are as destitute of trees as the mountains, except a few poplars or chinars (*Platanus orientalis*), which rise above the huts of the peasants, or the fruit-trees of the orchards, or perhaps a few other trees which have been planted on the margin of a watercourse.

Where the mountain-ranges approach the Caspian Sea and turn to the west, between 56° and 55° E. long., they probably occupy less than sixty miles in width, and their most elevated summits are not much higher than those of the ridges farther east. But west of 55° E. long., or west of the mountain pass of Bastam, they incline gradually a little to the south, and proceed in that direction to 52° E. long., where they again gradually decline to the north of west, until they terminate on the banks of the river Sefid-rud, at the pass of Rudbar. This portion of the range, which has received the name of the Elburz Mountains, forms a segment of a circle, the concave side of which is turned to the Caspian Sea. Near the point where the change in the direction of the range takes place is Mount Demavend, which rises to the height of 14,700 feet. Its declivities show many unequivocal signs of its having once been an active volcano. That portion of the Elburz Mountains which lies east of Mount Demavend, though considerably higher than the mountains farther east, probably nowhere exceeds 7000 or

8000 feet in height above the sea-level: the snow disappears from its summits about the beginning of May. The mountainous portion of the range may occupy a width of about 15 or 20 miles, but the lower hills which skirt it on the south and north increase its breadth to 50 or 60 miles. That part of the Elburz Mountains which lies west of Mount Demávend is much higher, several of the ridges being covered with snow even in the beginning of June. It consists of three elevated ranges, which, together with two valleys, cover a space about 30 miles wide, and on both sides are skirted by a belt of hills. Between the northern belt of hills and the shores of the Caspian Sea is a narrow strip of low land, called the Plain of Mazanderan and Ghilan.

The tract of country which extends along the southern side of the Elburz Mountains, and between it and the desert in the interior of Iran, may vary between 20 and 30 miles in width. In its eastern districts, where the adjacent mountains do not rise to a great height, it is ill provided with water, and resembles in soil and nearly every other particular the valleys of the mountain-region of Khorasan; but west of 53°, in the vicinity of Mount Demávend, where the mountains rise to a greater elevation, and are covered with snow more than half the year, numerous small rivers descend from them, and the valleys through which they flow are well cultivated. A change in the fertility of the country however occurs west of 51° E. long., where the most southern of the three ranges, composing the Elburz Mountains, does not rise so high as the two others which lie farther north; and being covered with snow only a few months in the year, it can only feed a small number of rivers. Irrigation is consequently very limited, and an undulating, stony, barren plain generally occupies the tract between the mountains and the desert. But the two valleys, which are enclosed by the three chains, and drained by the two branches of the Shahrud, called the Shahrud of Talkán and the Shahrud of Alamút, are very well watered, carefully cultivated, and populous. Each of these valleys is about 30 miles long, and they vary in width from two to three miles. By their union the Shahrud river is formed, which falls into the Sefid-rud above the pass of Rudbar; and the valley in which it flows for about 30 miles is wide and fertile. The northern declivities of the mountains are without wood.

The Elburz Mountains do not descend with a steep declivity towards the north, but are skirted by a hilly tract varying from twenty to thirty miles in width. The hills sink lower as they advance farther north and approach the shores of the Caspian Sea. The valleys between them are narrow; they may more properly be called ravines, scooped out by the torrents which descend from the range, and which, during the rains, run with inconceivable force. Up to a great elevation above the sea they are covered with thick woods of oak, beech, elm, walnut, and brushwood, with which cypresses, cedars, and box-trees are intermingled. On the gentle declivities of these hills, especially those which are some thousand feet above the sea-level, wheat and barley are cultivated to a considerable extent, and others serve as pasture-ground for cattle. Dairies are numerous, and well attended to.

The narrow tract of level ground which surrounds the southern extremity of the Caspian Sea, and goes under the name of the Plain of Ghilan and Mazanderan, extends from the mouth of the river Gourgan, which falls into the most south-eastern angle of the sea, to the mouth of the river Astarah. This tract considerably exceeds 300 miles in length; the width varies greatly, being much less to the west than to the east. West of 51° E. long. it is perhaps in no part more than four or five miles across, but it widens considerably farther east: the greatest breadth occurs between 52° and 53° W. long., where it is 30 miles wide in the meridian of the towns of Amol and Balfrush. Farther east it again grows narrower. This low tract is very little elevated above the level of the Caspian Sea, and as this sea, according to the latest measurement, is a hundred feet below the level of the Black Sea, it is evident that the plain of Ghilan and Mazanderan is below the sea-level. This circumstance must be considered one of the causes which give to this plain such an extraordinary climate, as is found nowhere else without the torrid zone, though this region is more than 14 degrees from the tropic of Cancer. The other causes which operate in producing this extraordinary phenomenon are the great expanse of water to the north, and the high range of mountains which enclose it on the south. Like the intertropical countries, this plain has a rainy and a dry season. Heavy gales commence in the month of September from the north and north-east, which drive the clouds against the mountain-wall of the Elburz, and the rain descends in torrents, accompanied by terrific thunder-storms. In a few hours large tracts of land are laid under water, and in the course of a few days all the small rivers which descend from the range inundate the adjacent country, and the roads are converted into almost impassable torrents. In the plain the rain continues to the middle of January; but on the slopes of the mountains it is converted into snow about the beginning of November. The water in the rivers is thus quickly diminished in quantity, and as their courses are rapid, the country soon becomes dry again. The quantity of snow which then falls in the higher parts is enormous. It is stated to rise in many places from one to two fathoms, and to carry away houses and villages. The mountaineers leave their abodes and retire to the plain. The melting of the snow in February and March does not produce inundations, owing to the short course of the rivers and the gentle slope of the hills. The spring, from March to May, is the most pleasant and healthy season. In summer, though rains are less frequent, the air contains much moisture, and the plain is almost continually enveloped in vapour and fogs, which give rise to several kinds of fevers and other dangerous diseases. The heat in summer is frequently oppressive. It is observed that a hot southerly wind sometimes springs up during the winter season, which instantly changes the temperature in a most remarkable manner, and dries wood and other inflammable substances to such a degree as to render them liable to take fire from the slightest spark. It sometimes lasts only a quarter of an hour, but generally twenty-four hours, and is immediately followed by a gale from the north-east, which brings snow and rain. This southerly wind is called by the natives the Bagdad wind. It is difficult to explain how it acquires such a degree of heat and dryness, as it blows over a country covered with snow.

This extraordinary climate produces a luxuriance of vegetation which is rarely met with even between the tropics, and is only exceeded by that of the coasts of Malabar and Chittagong, and of some islands of the Indian archipelago. The swampy tracts along the shores of the Caspian Sea are overgrown with saline plants and canes, which are extensively employed in building and for domestic purposes. At a short distance from the shores begin the forests, which cover the whole plain, and extend to a considerable elevation up the slopes of the hills. These forests contain numerous small villages, surrounded by extensive orchards and plantations of mulberry-trees and rice-fields, rice being the only grain which is cultivated. The vines frequently occupy large spaces, as well as the orchards, which produce figs, peaches, apricots, pears, apples, plums, and cherries; the pomegranate tree grows wild. It is however to be observed that in the lower and western portion of the plain which constitutes the province of Ghilan, the sugar-cane and orange-trees, which abound in Mazanderan, do not succeed, and are only cultivated as ornamental plants; cotton also does not grow, and the fruits have an acid and harsh taste. The sugar-plantations in Mazanderan are very extensive, and cotton is one of the principal objects of cultivation. In Ghilan the peasants are mostly occupied with the rearing of silk and the cultivation of rice. The plain of Mazanderan is somewhat more elevated than that of Ghilan, and its climate less humid, which evidently arises from the smaller elevation of the Elburz mountains at the back of Mazanderan than at the back of Ghilan, and the greater breadth of the plain.

The western portion of the plain of Ghilan separates the Caspian Sea from the table-land of Azerbijan, which constitutes the most northern portion of the great table-land of Iran, and lies between 36° and 40° N. lat. and between [illegible] and 49° E. long. A small portion of it, north of the river Aras, belongs to Russia. The general elevation of this table-land is 4500 feet above the sea-level, and perhaps nowhere sinks lower, though in many parts it rises higher, and in some parts to 6000 feet. Along its eastern side extends a mountain-range, which begins on the banks of the Sefid-rud, opposite the termination of the Elburz Mountains at the pass of Rudbar, and extends nearly parallel to the shores of the Caspian Sea in a north-west and northern direction to the banks of the Aras, where it terminates not far from that river on the boundary-line between Russia and Persia. This range, which is uninterrupted, is about 150 miles long, and about 20 miles wide. It is called the Massula Mountains. It rises from 6000 to 7000 feet above the sea-level, or about 2000 feet above the table-land. To the west of it, and at a distance varying from 6 to 30 miles from the Massula Mountains, is another and apparently higher range, which, even at the mountain-passes, exceeds 8000 feet of elevation; and in Mount Sevellan (north of 38° N. lat.) rises to about 12,000 feet: but this range is broken by the river Sefid-rud below Miana, and does not extend far north of Mount Sevellan. The table-land of Azerbijan is bounded on the west by the numerous ranges of the Kurdistan Mountains. The surface of the table-land in general is hilly, but the hills do not rise into mountains, except between 36° 30′ and 37° 30′ N. lat., where several high ranges occur, as the mountains of Kibleh and the Kalifan Koh, which perhaps rise to 2000 feet above their base. This tract seems to contain the highest portion of the table-land, and the ranges of hills form a connection between the Kurdistan Mountains and the Massula Mountains. The levels between these ranges are not in general extensive enough to be called plains, though in some parts they are several miles wide. But farther north, several of them from extensive plains, among which that surrounding the lake of Urumiyeh is by far the largest. Though in several places traversed by narrow and low ranges of hills, which terminate at a small distance from the shores of the lake, the plain extends in general from 20 to 30 miles from it, and at Tabriz even 50 miles. From the hills and mountains which enclose the basin of the lake an immense number of perennial streams descend, and are much used for irrigation. The rice-fields are extensive, and produce rich crops: the meadows are equally large, and horses, buffaloes, cows, and sheep are abundant on the pasture-grounds. But the greatest wealth of this plain consists in its large orchards, which yield abundance of peaches, nectarines, apricots, plums of all sorts, cherries, pears, apples, and grapes. There are also plantations of poplar and chinar, but the mountains and hills are generally devoid of wood. In the other plains, which are much less in extent, and have not the advantage of abundant water, the cultivation is limited, and they are chiefly used as pasture-grounds by the nomadic tribes. The climate of this table-land is cold in winter, but very temperate in summer. During several of the winter months it is covered with snow, and the cold is sometimes very intense, except on the plain around lake Urumiyeh, where the winters seem not to differ much from those of Northern Italy. The royal family of Persia abandon the town of Teheran in summer, and retire to Sultaniyah, in the southern districts of the table-land.

The mountains of Kurdistan occupy a broad belt of country along the western edge of the table-land of Iran. Mount Ararat may be considered as standing at the northern extremity of the mountains of Kurdistan. Its summit is 17,310 feet above the sea level, and it is the highest mountain in western Asia, or to the west of the Hindu-Coosh. The plain which extends along its northern base, and which attains an elevation of about 5500 feet above the sea level, separates it from the mountains which enclose the Black Sea on the south and east. From its southern base mountains branch off to the south and south-west, which enclose the lake of Van, and extend considerably in width, so that near [illegible]° N. lat., the whole country between the plains of Urumiyeh and the river Tigris is occupied by mountain-ridges and valleys, a space extending about 180 miles from west to east. The ranges which enclose the lake of Van seem to be the most elevated part of the Kurdistan mountains, the summits of Supan Tagh, Nimrud Tagh, Argerosh Tagh, and idesh Tagh rising above the snow-line. The mountain region extends from the lake in a south-eastern direction, and does not seem to decrease in width until it approaches [illegible]° N. lat., where it is probably not much more than 100 miles wide. Farther south it grows still narrower, and south of 35° it is hardly more than 70 or 80 miles wide, a breadth which it preserves to its termination, which may be fixed in 30° N. lat., where the mountains of Farsistan begin. The last-mentioned range may be considered as the continuation of the mountains of Kurdistan. The northern portion of this extensive mountain region, and as far south as 35° N. lat., is nominally subject to the Turkish emperor; but the nomadic tribes which inhabit it are independent under their hereditary chiefs, who frequently make predatory excursions into the neighbouring countries. This portion, with the exception of the road which leads from Tabriz, in Persia, to Van, and thence to Diarbekr, has seldom been visited by European travellers. It seems that the whole is almost entirely occupied by mountain-ranges, and that the valleys are narrow, but there are excellent pasture-grounds on the declivities of the mountains. Some summits appear to attain a great elevation, especially Mount Jawar, near 37° N. lat., nearly in the centre of the region. That portion of the Kurdistan mountains which lies south of 35° N. lat., and is subject to Persia, has lately been visited by many of our countrymen. The central portion of this region consists of a succession of mountains and narrow valleys, but towards its eastern and western edges there are wide valleys, or rather plains, a part of which is under cultivation, though the larger portion is generally used as pasture-ground. The mountains differ from those which surround the table-land of Iran, especially in their declivities being wooded with oak, which, near the base of the mountains, grows to a large tree, but higher up is stunted. The plains and valleys of this region probably occupy one-third of the surface. The ridges, frequently four, five, or even six in number, run in the direction of the whole range, and are frequently united by transverse ridges. But there are also several valleys which run across the ranges, as is evident from the courses of the rivers; for nearly all those rivers which join the Tigris south of 30° N. lat., and traverse this mountain region, do not rise within the range, but to the east of it, on the plains of the table-land of Iran, such as the Great Zab, the Diáyálah, and the Kerkhah. Though several summits and ridges attain a great elevation, being for nine or ten months covered with snow, only two summits rise above the snow-line: one of them is situated on the most western ridge, called Kebir Koh, near 33° 15′ N. lat., and the other in the ridge, called Koh Mungasht, near 31° 25′ N. lat.

That part of the great plain traversed by the Euphrates and Tigris, which belongs to Persia, lies between the mountains of Kurdistan, and the banks of the Tigris and Shat el Arab. It is about 100 miles long, and, on an average, 30 miles wide. The lower portion of it, which lies along the great river, and comprehends nearly one-half of the country, is swampy and uninhabited, owing to the badness of the air, and the difficulty of draining the ground. About fifteen miles from the banks of the river, the country is considerably higher, but as the soil is composed partly of sand and partly of a hard clay, it cannot be cultivated, except along the banks of the rivers, and even there cultivation is very limited. The greater part of the country is a waste, which does not yield pasture, except for camels. This more elevated tract is called Chad, or Kaaban.

The country which lies east of the Kurdistan mountains, and between them and the Kuweer, or Salt Desert, belongs to the table-land of Iran. Its general elevation above the sea in the southern districts exceeds 4000 feet, and rises in some parts to 6000 feet; but north of Ispahan it sinks down to 2500 feet, and in some places even lower. It is a plain traversed by numerous ridges of rocky hills, which generally run from west to east, and sink gradually into the desert farther east. Few of these hills are more than 1000 feet above their base, and generally not half so much. The valleys are open and wide, in some parts exceeding ten or fifteen miles in width; they are also very long. Here too, as in most places on the table-land of Iran, cultivation is limited for want of water. As the eastern ridge of the Kurdistan mountains does not rise high enough to be covered with snow for many months, the rivers which descend from them are scarcely provided with water during a great part of the year; and the little that they furnish is absorbed in irrigation. The valleys are consequently, for the most part, uncultivated, except in the vicinity of the villages, and these villages only occur at great distances from one another. It is however certain that a much greater portion of these valleys was formerly under cultivation, and that the decrease of agriculture in these districts must be ascribed to an oppressive government and the incursions of the nomadic tribes which are in possession of the mountains of Kurdistan.

The mountain region of Farsistan and Kerman occupies the whole of Persia south of 30° N. lat., from the mouth of the river Tab to Cape Jask (from 50° to 58° E. long.), a distance nearly 500 miles in length, and nearly 200 miles in average width. On the south it is washed by the Persian Gulf, and on the north it borders on that part of the great desert which is called the desert of Kerman. Along the shores of the gulf is a low and sandy tract, varying in width from 20 to 30 miles, the soil of which is impregnated with salt. It has a very hot dry climate, and produces nothing but dates. The natives call it *Dushtistan* or *Gurmsir*, that is, the warm region. No river falls into the Persian Gulf which is navigable, even for small boats, more than a few miles inland. It is asserted that the Gurmsir is slowly increasing in width by the retiring of the sea. At the back of this low tract the country rises in steep and bare rocks to the height of mountains, and constitutes an elevated region which extends more than 100 miles inland, where it stretches out in a plain traversed by low rocky ridges running east and west. About 50 miles from the sea, the lowest part of the mountainous tract is about 2500 feet above the sea-level, but where it approaches the plain it attains the height of 4000 feet. This mountainous region is called *Sirhud* (the cold country), in opposition to Gurmsir. In its northern districts, where it is connected with the mountains of Kurdistan, the rocky ridges, which traverse the surface longitudinally from west to east, rise to 7000 or 8000 feet, and in these parts they are partially wooded. But south of 29° N. lat. they do not appear to attain so great an elevation, rising probably only from 1000 to 2000 feet above their base, which in many places cannot attain a great elevation above the sea, as the valleys enclosed by the ridges produce the date. The ridges, though generally of inconsiderable width, are numerous, and the valleys are narrow, except towards the north, where they are from 15 to 20 miles across. The mountains are barren and destitute of vegetation, but the valleys are rich in fruits, and even grain, where they can be irrigated. The plain which extends along the northern side of the mountain region, and which is from 60 to 100 miles in width, has a soil strongly impregnated with salt, and contains several smaller salt lakes, besides the large salt lake of Bakhtegan. It would form a portion of the great desert, if it were not divided from it by a nearly continuous series of oases, which stretch east and west through it, between 29° and 30° N. lat., and which are enclosed on the north and south by two low ridges of rocky hills. This narrow fertile tract, called the *Nurmanshîr*, produces some grain, but it is particularly rich in several kinds of fruit, which attain great perfection.

Having surveyed the countries which surround the Great Desert of Iran on the north, west, and south, we shall notice the desert itself, as far as it is included within the boundary of Persia. The desert has its greatest width on the eastern border of Persia. Between the Nurmanshîr and the town of Herat it is more than 350 miles across. Pottinger says that from the mountains of Beloochistan, which between 60° and 62° E. long. form an extensive mountain region which advances as far as 31° N. lat., a narrow though at intervals very lofty ridge branches off in a northern direction, and extends, between 59° and 60° E. long., so far to the north that it seems to be united to the Khorasan Mountains to the westward of Herat. This ridge divides the sandy desert of Seistan from the salt desert of Persia, and in or near it the town of Khubbee seems to be situated, which is said to be at an equal distance from the Nurmanshîr and the town of Herat. Farther west the desert is not so wide, but near 55° E. long. it is probably still 250 miles across. From 55° E. long. it narrows more rapidly, so that at its western extremity, which occurs between 50° and 49° E. long., south of the town of Casbin, it hardly exceeds 30 or 40 miles in width. The desert is called by the Persians Kuweer. 'The nature of this desert,' says Fraser, 'varies in different places. In some the surface is dry, and even produces a few of those plants which love a salt soil; in others we find a crackling crust of earth, covered only with a saline efflorescence. A considerable portion is marshy, and during winter the melting of the snow and the increase of the torrents occasion an accumulation of water in the low parts. In the hot months much of this is evaporated, and leaves behind a quantity of salt in the form of cakes upon a bed of mud. In certain spots sand predominates, either in the shape of heavy plains or wavelike hillocks, easily drifted by the wind, and sometimes so light and impalpable as to prove extremely dangerous to travellers, who are not unfrequently buried in its heaps.' In several parts of this desert rocks rise abruptly, though in general only to a moderate elevation. These rocks usually form short ridges, and serve only as a place of refuge for the robbers, with whom the desert is infested along the roads. In several places however the rocks extend over several square miles, and contain between them small plains or valleys, in which water is found for the greater part of the year, and which are cultivable and inhabited. They thus constitute extensive oases. The largest of these oases form a series across the desert between Herat and Ispahan, extending from the first-mentioned town westward to Tubbus, from Tubbus southward to Yezd, and from Yezd westward to Ispahan. The towns of Tubbus and Yezd are situated in the most extensive of these oases. The smaller oases, which are traversed by the road that connects these towns, are generally 20 or 30 miles distant from each other, and in some places the distance is still greater.

Rivers and Lakes.—The table-land of Iran, together with the mountain regions which surround it on the north and south, is very sparingly watered. The southern mountain-ranges are too bare and also too low to attract sufficient moisture to form perennial streams, except in a few places. The northern mountains give rise to a much greater number of watercourses; but as soon as they enter the plain, and sometimes before, the small volume of water which they bring down during the greater part of the year is absorbed in irrigation, and only a few of these streams reach the desert, where they are lost in the dry and thirsty soil. Only those parts of Persia which are included in the plains of Ghilan and Mazanderan, in the table-land of Azerbijan, and in the mountains of Kurdistan, are well watered. The rivers of Ghilan and Mazanderan have a short course, but they are usually navigable for some miles from their mouths, where the woods on their banks do not form an impediment. The most considerable river in the table-land of Azerbijan is the Sefid-rud (or White River), which is also known and marked on our maps by the Turkish name of Kizil Uzen or Ozien. It rises within the mountains of Kurdistan, south of 36° N. lat., and traverses the most mountainous portion of the table-land of Azerbijan; it runs by a very circuitous course, first east-north-east for about 100 miles, and then about the same distance northward; when near 37° 30′ N. lat., it breaks through the western chain of the mountains of Massula, and turns to the south-east, in which direction it flows upwards of 80 miles, draining the valley between the two ranges of the Massula mountains. When it approaches the western extremity of the Elburz range, it is joined from the east by the river Shahrud, which drains the valleys of the western portion of the Elburz mountains, and runs about 100 miles. After its junction with this river, the Sefid-rud flows for about 30 miles in the narrow valley which separates the Elburz mountains from the eastern Massula range, and enters the plain of Ghilan, through which it flows into the Caspian Sea. The whole course of the Sefid-rud may be about 350 miles. On the table-land of Azerbijan the bed is generally many hundred feet, and sometimes a thousand feet, below the adjacent country. Thus it cannot be used for irrigation, and though the banks are less elevated above the pass of Rudbar, still the waters can nowhere be used to fertilise the country. In the plain of Ghilan the current is not rapid, but the river is not navigated, there being no place of any importance on its banks, which are very low and swampy. Two rivers, each running about 100 miles, fall into the lake of Urumiyeh, the Aji, which runs some distance north of Tabriz, and the Iaghâtu, which falls into the lake not far from the most south-eastern angle. Both are extensively used to irrigate the valleys through which they flow, and also the plain of Urumiyeh. The rivers which drain the mountains of Kurdistan and its numerous valleys are not navigable within the mountains, as their course is frequently broken by rapids and cataracts; and where they enter the plain, they are not navigated, the adjacent country being nearly uninhabited. Three of these rivers run between 200 and 400 miles: the Diáyâlah, which joins the Tigris below Bagdad; the Kerkhah, which falls into the Shat el Arab a few miles below Kornah; and the Karoon or Kuran, which joins the same river at the point near its mouth where it begins to divide into numerous branches.

As a great part of the soil of Persia is impregnated with salt, the few lakes which occur are salt also, except in Ghilan and Mazanderan, where there are several small lakes of fresh water. The most considerable of the lakes of Persia is that of Urumiyeh or Shahee (called Spauta by Shahed, which is more than 80 miles long, and about a third of that distance in extreme breadth. The greatest depth of the water is four fathoms, and the average depth about two fathoms; but the shores shelve so gradually, that this depth is rarely attained within two miles of the land. The water is much salter than that of the ocean. It is stated that its specific gravity is 1·165, while that of the Atlantic near the equator is 1·028, and that of the Baltic only 1·0049. A vessel of 100 tons burden, when loaded, is said not to draw more than from 2 to 3 feet. A gale of wind raises the waves only a few feet, and as soon as the storm has passed, they subside in a few minutes. It contains no fish, but the smaller classes of zoophytes are found in considerable quantity. The lake receives a great number of rivers, some of which are considerable, as the Aji and Jaghatu, but it has no outlet. The mountain region of Farsistan contains the salt lake formerly called Bakhtegan, but now Deryá-e-Niriz, or the Lake of Niriz. This lake has no outlet, and the country on its shores is without vegetation and uninhabited. [Bakhtegan.]

Climate.—The climate of the plain of Ghilan and Mazanderan has already been described. That of the Ghermsir, or the low and sandy tract along the Persian Gulf, is distinguished by its great heat and dryness, and is therefore the country most suitable to the growth of date-trees, which only bear valuable fruit where these two circumstances concur. It is extremely unhealthy during the summer heat, and is then almost entirely abandoned by the inhabitants, who retire to the adjacent mountains. In the interior of the table-land the climate is very hot in summer, but cold in winter. In summer however the air is dry and the sky cloudless. In winter it is not so dry, and a good deal of snow falls, not however sufficient to render the dry and sandy soil fit for maintaining constant vegetation. The quantity of snow which falls on and near the mountain regions appears to be much greater than that which falls in the centre of the table-land; and this probably is one of the principal reasons why the former exhibit a considerable degree of fertility, especially where the vegetation can be supported by irrigation; while the central part of the table-land is a desert, and the oases within this desert are more fit for plantations of fruit-trees than for the cultivation of grain. *Fraser* observes that about the end of November he found the whole plain surrounding Teheran, which is near the most northern edge of the table-land and not far from the foot of the Elburz range, covered with snow; and at the arrival of Morier at Teheran, about the middle of March, there was still ice. The month of April is cold, and northern winds then prevail. As these winds come from the mountains, which are then entirely covered with snow, they are very cold. The mild weather does not commence before the end of April, when the transition from cold to heat is very rapid. In this season the thermometer at sunrise stands between 51° and 55°, but at noon it rises to 70°, and in the afternoon a very hot south-eastern wind generally blows, which renders the heat in the streets nearly insupportable. On the 19th of April the thermometer rose to 82°. The climate of Teheran during the summer is subject to sudden though not great changes, which may probably be ascribed to the vicinity of the mountains. The climate is much more regular and constant in the other mountain regions.

Productions.—Agriculture is well understood and carefully attended to, as is evident from the means of irrigation employed, and especially the subterraneous aqueducts. But extensive tracts, which were formerly under cultivation, are now a desert, or serve only as pasture-ground, owing to the predatory incursions of the neighbouring wandering tribes. In other tracts, which are cultivable, grain is not raised, but they are kept in their natural state as pasture-ground for the Ilyats, or wandering tribes who live within the boundaries of the empire.

Rice, wheat, and barley are the most usual crops, but there are also millet (*Holcus sorghum*), maize, lel, or mashmung, dal, a species of vetch, and several kinds of beans and pease; cotton, indigo, sugar, tobacco, and madder are raised in many places, but especially in Mazanderan. The fruit-trees are managed with great care and skill, and many places are distinguished by their excellent fruit, which furnishes a considerable article of internal trade. The date grows only in the Ghermsir and some of the lower valleys in the mountains of Kerman; but other fruits grow in most places, and more especially in the oases in the middle of the desert. These fruits are apricots, peaches, nectarines, plums, apples, pears, quinces, figs, pomegranates, mulberries, currants, cherries, almonds, walnuts, and pistachio-nuts. The vine plantations are very extensive, though wine is made only in a few places by the Christians. The melons of Persia are distinguished by their size and flavour. The chief culinary vegetables are turnips, carrots, cabbages, lettuces, cauliflowers, radishes, celery, onions, garlic, parsley, and cucumbers. Forest-trees do not occur, except on the northern declivity of the Elburz mountains. The oak, which covers large tracts of the mountains of Kurdistan, does not grow to the size of a timber-tree. One of the most remarkable vegetable productions of Persia is the plant from which assafœtida is obtained. The poppies which produce opium are cultivated all over the table-land, and in many places saffron also is cultivated.

The domestic animals of Persia are camels, horses, asses, mules, black cattle, buffaloes, sheep, and goats. There are three sorts of camels in Persia; those with one hump, those with two, and a third produced by the union of these varieties; the last are preferred on account of their strength, docility, and patience. They carry from 700 to 1100 lbs. English. The Persian horses are noted for their beauty, strength, and speed, especially those of the Turkoman tribes. The race has been much improved by crossing with Arabian horses. It is hardly possible to conceive what journeys they are able to perform. The finest horses will fetch from 80*l.* to 100*l.* Even the common horses are good and strong, and a kind of pony, called *yaboo*, is much esteemed for strength and endurance. Asses are numerous, and some of them of superior size and description. Mules are used for the transport of goods more than any other animals; they are very strong, and usually carry about three cwt. The black cattle of the plain of Mazanderan are distinguished by size and beauty, and they have the Indian hump. Sheep are very numerous in all the parts possessed by the nomadic tribes; they are principally of the fat-tailed kind.

Though Persia, owing to the want of forests and the barrenness of the soil, is not largely stocked with wild animals, there is a great variety in the different parts. The lion is found on the plains along the Tigris, in Farsistan, and some other places. [Lion.] Leopards, cheetahs or hunting leopards, tiger-cats, lynxes, and bears, are more numerous. Hyænas, wolves, jackals, and foxes abound. Antelopes are numerous, and several sorts of deer are found. The wild ass (onager), called by the natives *gour khur*, is not often met with, but it is found over all the plains and rocky regions of the country, particularly in the deserts of Khorasan and the extensive valleys of Farsistan and Irak Ajemi. Wild boars, porcupines, and hares are common. Among the most remarkable wild animals are the *argali*, or mountain-sheep, and the *boz* or *pazan*, or mountain-goat. Birds are numerous only in a few places. Pheasants inhabit the plain which surrounds the south-eastern corner of the Caspian Sea; and bustards, partridges, desert-partridges, herons, wild ducks, and pelicans occur in many places. Blackbirds, thrushes, and nightingales are frequently heard in the underwood of the plains of Ghilan and Mazanderan, and in the thickets of roses which embellish every garden. Fish abounds only in the Persian Gulf and the Caspian Sea. Sturgeons and sterlets in great numbers ascend the small rivers which fall into the Caspian Sea, though not in such shoals as in the Volga. As the Persians themselves are not fond of fish, they have permitted the Russian fishermen to establish themselves near the mouths of these rivers, where they prepare caviar and isinglass, but the body of the fish is thrown away. Locusts frequently lay waste extensive tracts of country. Bees are common in many places, and much honey is collected. The silkworm furnishes the principal article of commerce in the plains of Ghilan and Mazanderan, but it is also reared in several other places.

Iron is abundant in many places, but it is not much worked. Lead mines are worked in some districts on the table-land of Azerbijan, and in Farsistan and Kerman. Copper has been discovered in Azerbijan and other places. Antimony is also found, but it is little used. Rock-salt is plentiful, and great tracts of the plain are covered with salt incrustations. Several kinds of bitumen are met with in some places, among which is naphtha and the celebrated momy or mummy, which is only collected in Farsistan, in the vicinity of the town of Darab or Darabgherd.

Inhabitants.—The population of Persia is differently estimated. Some think that it hardly exceeds seven millions, but others increase it to fifteen millions. It consists of a great number of nations, who speak different languages; but all of them belong to the Caucasian race. Many of these nations still adhere to a wandering life; it is even said that one-fourth of the population consists of nomadic communities, who form almost a distinct class from the nature of their habits and their modes of gaining a livelihood. That portion of the population which has fixed abodes consists of Persians and Parsees, of Armenians and Arabians.

The Persians, who are distinguished among the nations of Western Asia by the politeness of their manners and the degree of scientific knowledge which they have acquired, constitute the bulk of the population, and are merchants, agriculturists, and manufacturers. The number of the Parsees is small; and they appear to be numerous only in the oasis of Yezd. Their language differs considerably from that of the Persians; they are not Mohammedans, but adhere to the religion of Zoroaster, as it is contained in the Zend Avesta, and adore fire as the symbol of the divinity. They are distinguished by the purity of their life and their honesty in all transactions, and occupy themselves mostly with agriculture and the raising of fruits. Many of these fire-worshippers, when persecuted by the Mohammedans after the conquest of their country by the Caliph Omar (A.D. 642), left their homes and emigrated to India, where numerous communities still exist at Surat and Bombay. In India they are merchants, and highly esteemed for their honesty. The Armenians live in all the great towns, where they are merchants: they also cultivate the ground, and are particularly numerous in the western districts of the table-land of Azerbijan, where they exclusively occupy whole villages, and have obtained the esteem of the Mohammedans by their industry in agricultural pursuits. Arabians form the bulk of the population in Dushtistan or Gurmsir, where they gain their livelihood as fishermen, seamen, planters of date-trees and merchants.

The wandering tribes of Persia are comprehended under the general term of *Iliyats* or *Ilat*, and are found in every part of Persia; but many of them have become inhabitants of cities and villages. These tribes are accordingly divided into *Shehr-nishin*, or dwellers in cities, and *Sahra-nishin*, or dwellers in the field. A considerable number of them adhere to their original mode of life, and live all the year round in tents, in the winter keeping to the plains, and in summer seeking the pasture of the mountains. The wealth of the Sahra-nishin consists in cattle. They breed camels and horses for sale, and their sheep yield milk, which is made into *raughan* (liquid butter), and sold throughout the country. Their peculiar privileges consist in liberty to range over districts from which no one can exclude them. In the summer they ascend to high mountain-plains and the declivities of the mountain-ranges, where they find abundant pasture, which is called *yaïlâck*, and in the winter they keep to their *kishlâck*, or tracts which enjoy a warmer climate. They pay a tax to government, which is collected by their own chiefs, and are obliged to furnish a certain number of soldiers to serve on foot and on horseback, for which service however the individuals are paid. They are difficult to discipline, owing to their clan-like propensities. They feed principally on the produce of their flocks, and eat sour milk, cheese, dough, or butter-milk, and much raughan. Some of these tribes have the almost exclusive possession of large tracts of country, and consist of a great number of individuals. The most numerous are the Lurs, who inhabit that portion of the mountains of Kurdistan which lies south of 34° N. lat., and comprehends the province of Luristan, together with the mountainous part of Khuzistan. They are subdivided into two great tribes: the *Proper Lurs* occupy the country called Luri Kuchuk, which is situated between the Kerkhah on the west, and the Dezful, a tributary of the Kuran, on the east. They consist of 58,000 families. To the east of the Dezful are the Bakhtiyâris, whose country is called Luri Buzurg, and extends over the mountains of Khuzistan. They consist of 28,000 families. A small number of these tribes are Shehr-nishin, but their country contains towns and villages inhabited by persons who do not belong to these tribes. The language of the Lurs differs slightly from that of the Kurds in the province of Kermanshah, and a person conversant with one dialect can perfectly understand the other. Major Rawlinson is inclined to regard both dialects as derived from the old Farsí, the Farsí Kadím, as it is called. The mountains west of the river Kerkhah are in possession of some Kurdish tribes, among which the Guran, Mikri, and Rewendi are the most numerous: the two last-mentioned tribes contain about 12,000 families each. Many of them, especially the Mikri, have almost entirely abandoned their wandering habits, and cultivate the ground.

The Kurds are also in possession of a large tract of the mountain-region of Khorasan, on the northern border of the table-land of Iran. They do not originally belong to that country, but, according to Morier, were transplanted thither by Shah Ismael, to protect the neighbouring countries against the predatory incursions of the Turkomans, who inhabit the desert plains of Turkistan, and who frequently entered Iran by the large break which occurs in this part of the mountain-range. Only 4000 families were originally settled there, but they have increased to more than 50,000. They effectually protect the frontier, but have themselves become robbers, and frequently lay waste the neighbouring valleys and plains, and raise the standard of rebellion against the sovereign of Persia. They are governed by five chiefs, of whom the khan of Kubushan is the most powerful. He has from 25,000 to 30,000 families under him, of which number two-thirds are Sahrâ-nishín. They have preserved their language, which also resembles the old Farsi, but have adopted the dress of the Persians. To the south-east of these Kurds, between the towns of Mushed and Herat, there is a tribe of Arabs, which was transported to this country from Nejd by Shah Ismael, for the same purpose. They originally consisted of from 2000 to 3000 tents, but have increased to about 6000 tents. They retain their pastoral habits, and are almost all Sahrâ-nishín, or dwellers in the field. They are of the Sunni sect, and partly preserve their language, though they have changed their national costume.

Besides these tribes, which almost exclusively occupy large tracts of country, there are others which are dispersed over other parts, but constitute only a small portion of the population. They are all of Turkish origin, with the exception of the Lak, or Lek, who are considered Persians, and are dispersed throughout the country, but their principal seats are about Cazvin, and in the provinces of Fars and Mazanderan. Their total numbers are reckoned at about 20,000 houses, and they live partly in cities and partly in the plains. Among the Turkish tribes the most remarkable is that of the Kajar, to which the present sovereign family belongs. It came from Turkistan to Persia under Oguz Khan, grandson of Gengis, and settled near Cazvin and Erivan. It is a small tribe, not containing altogether more than 4000 houses. All the members of the tribe are now Shehr-nishin, or dwellers in cities. The Afshars, from which tribe the family of Nadir Shah sprung, number altogether about 20,000 houses, and are dispersed over Irak Ajemi and Khorasan. They principally reside in towns. The most numerous of the Turkish tribes are the Shekagi and the Shah-seven, whose principal seats are in Azerbijan. The first-mentioned tribe consists of about 50,000 houses, and from it the greatest number of the Persian foot-soldiers are drawn. The Shah-seven are calculated at 20,000 families, and make also excellent soldiers. They live mostly in tents, and speak Turkish.

Political Divisions, Provinces, and Towns.—Persia is divided into several governments, whose limits however are frequently changed, and accordingly geographers preserve the antient division into provinces, though in this respect also some changes have been introduced. The provinces are at present twelve in number. Seven lie along the western boundary-line: Azerbijan, Kurdistan, Luristan, and Khuzistan, along the border of the Turkish empire; and Farsistan, Laristan, and Kerman, along the shores of the Persian Gulf. The interior of Persia is occupied by the two large provinces of Irak Ajemi and Khorasan; and along the shores of the Caspian Sea extend the provinces of Ghilan, Mazanderan, and Astrabad.

1. Azerbijan. [AZERBIJAN.]

2. Kurdistan comprehends the mountain region of the Kurdistan range between 36° and 34° N. lat., about the sources of the rivers Sefid-rud, Diyalah, and Kerkhah; it is separated from the Pashalik of Bagdad on the north by the eastern range of the Kurdistan Mountains, called Shahu Mountains, and farther south chiefly by the course of the river Shirwan, a branch of the Diyalah. It is main

separated from Luristan by the river Kerkhah. It is divided into two parts; the north-eastern part, called Ardelan, is subject to a Kurdish chief, and the south-western, called Kermanshah, principally belongs to Persia. The first part, comprehending the country surrounding the upper branches of the Sefid-rud, which is about one-third of the province, consists of a succession of well-wooded mountains and narrow valleys, and has excellent pasture-grounds. It contains Sehnah, the residence of the Kurdish chief, who lives in a sumptuous palace, built on a small hill in the middle of the town. It contains, according to Rich, between 4000 and 5000 families, among which 200 are Jews, and 50 Chaldæan Christians of the Catholic communion. Kermanshah also is principally mountainous, but there are fine wide open valleys along the rivers Shirwan and Kerkhah, and pretty extensive plains near the outer edges of the mountain region: both the valleys and plains are generally well cultivated. Kermanshah, the capital, a flourishing town, is situated in the southern extremity of a fine plain, through the centre of which runs the Karasu, an affluent of the Kerkhah. It contains about 12,000 houses, and has many public buildings. It carries on a considerable commerce, being on the great caravan road which passes across the mountains between Bagdad and Hamadan, Ispahan, and Teheran. This road seems always to have been a great thoroughfare, and ruins of great antiquity occur along it. About six miles from Kermanshah, on the face of the mountains which enclose the plain on the north, are excavations and sculptures of great extent, called Takt-i-Bostan. Where this range of mountains terminates on the east, on the banks of the river Kerkhah, are the sculptures of Besittoon. [Besittoon.] About 30 miles farther east, also near the road, there are extensive ruins, among which those of a temple of Artemis are the best preserved. They occur near a village called Kengawar, which is about 30 miles west-south-west of Hamadan. [Ecbatana.]

3. Luristan, which lies between the Kerkhah and the Dizful, an affluent of the Kuran, is entirely occupied by mountains and narrow valleys, except some plains of moderate extent near the outer ridges of the mountain region. These plains alone are under cultivation, the remainder serving only as pasture-ground to the different tribes of Lurs who inhabit it. In the centre of the mountains is an extensive tract, 70 or 80 miles in length, in which no human dwelling is met with, and which is traversed in its length by the road leading from Dizful in the province of Khuzistan to Khorrám-abad. There is no town in this province, except Khorrám-abad, which stands in a fertile and tolerably extensive plain at the northern extremity of the mountain desert. The town contains about 1000 houses, and is built on the south-western face of a steep rock, on which a strong fortress and palace are erected.

4. Khuzistan comprehends the southern part of the mountains of Kurdistan and that part of the plain of the Tigris which belongs to Persia. It is therefore naturally divided into two portions. The plain, which is in possession of some Arab tribes, contains good pasturage in the northern and western districts, and here the wandering Beduins pitch their tents. But the southern and eastern portion of it is a sandy desert, occasionally intersected by extensive morasses, and only cultivated in some places on the banks of the rivers, where rice and some wheat and barley are raised. There are also a few plantations of date-trees. In this part of the plain is the town of Dorak, or more properly Felahi, on the banks of two of the branches of the river Jerabi: it is a large place, the walls of which are two miles in circumference; but notwithstanding this, the houses are few, as the majority of the people live in the suburbs under the shade of the date-trees. This town is celebrated for its manufacture of Arabian cloaks, which are exported to all parts of Persia and Arabia. Endian, which is situated near the most southern extremity of the province, on both banks of the Tab, has some trade with Básra, or Bassora, and from 4000 to 5000 inhabitants.

The mountainous part of the country contains several plains and valleys of great extent, which are fertile, but only partially cultivated, among which the valley of Ram Hormuz, which is 40 miles long and from six to eight miles wide, is distinguished by its soil and picturesque beauty. Between the higher ranges of the mountains and the level plain runs a hilly tract several miles wide, which contains a large portion of cultivable land, though at present only the borders of the rivers are under cultivation. It is however the most fertile portion of the province. The high mountain-ranges in the eastern districts of the province are in possession of Lurish tribes, which have almost entirely settled in villages, and cultivate the ground. Tobacco is extensively grown and exported. The present capital of the province is Dizful, on the river of the same name, a considerable place, with 20,000 inhabitants, and a fine bridge over the river. About 10 miles south-west of this town are immense heaps of ruins, on both sides of the river Kerkhah, which mark the site of Susa. [Susa.]

The second town of the province, and formerly the capital, is Shuster, which stands not far from the high mountain-ranges on the river Kuran. The houses are good, being principally built of stone, but the streets are narrow and dirty. There is a considerable manufacture of woollen stuffs, which are exported to Bassora in return for the Indian commodities brought from thence. It has lately suffered much from the plague; but the population still amounts to 15,000. The town is supplied with water by extensive hydraulic works. The mountains east of Shuster are traversed by roads leading to Irak Ajemi and Farsistan; and though they are now little frequented, the extensive ruins which exist in the valleys and plains along these lines of road show that large towns were once situated on them. They have not however been visited by Europeans, being situated in a country which offers few attractions, and is in possession of tribes which pay little obedience to the king of Persia. According to the information which Major Rawlinson has collected from the natives, there are extensive ruins in the plain of Mal Amir and others near Gilgird. He thinks that those in the plain are the ruins of the town of Eidij, and that the others belong to the Susan of the Scriptures. There are also sculptures near Gilgird, which are like those of Besittoon. These ruins are the most northern of the numerous remains of antient magnificent buildings which are dispersed over the mountain region of Farsistan as far as the town of Darabgherd on the borders of the province of Kerman, and which evidently show that this part of Persia was once the seat of a rich and powerful monarchy.

5. Farsistan, or Fars, the antient Persis, comprehends nearly one-half of the Dushtistan, a low, hot, sandy strip which extends along the shores of the Persian Gulf, the northern portion of the mountain-region of Farsistan and Kerman, and the hilly plain which extends north-eastward to the lake of Bakhtegan and the Great Desert. The mountain-ranges, which in this part separate the table-land of Iran from the Persian Gulf, are hardly more than 30 or 40 miles wide, but exceedingly steep towards the sea. They consist of three or four rocky ridges, which can only be crossed by narrow roads over rugged mountain-passes. The most frequented road leads from the harbour of Bushire to the towns of Kazerun and Shiras. It passes to Kazerun over four ridges through the kotuls (mountain-passes), Mulloo, Khescuht, Komaredge, and Tag-i-Turkan. Between Kazerun and Shiras the kotuls Dókhter and Pirazun are to be traversed; for though Kazerun is situated on the table-land, there are several ridges on it which rise to a considerable elevation, especially in the northern districts. The less mountainous portion of the table-land, which lies farther south, contains several salt lakes. Though there are many well-cultivated districts in this province, a great portion of it is nearly desert, especially towards the north. The southern part of the coast, east of Ras (Cape) Berdistan, is occupied by Arabs, who acknowledge the authority of the iman of Muscat; and in the northern districts there are some tribes of Kurds. In that part of the coast which is subject to the iman are the town and harbour of Congoon, near Cape Berdistan. The town is stated to have 6000 inhabitants, and some trade is carried on with Bassora, Muscat, and the different towns on the Persian and Arabian coasts. Near it is an excellent roadstead, where a frigate may lie at anchor in safety. The principal commercial place is Bushire, or Aboushehr. [Aboushehr.] The principal towns in the interior, from west to east, are Behaban, Kazerun, Shiras, Firoze-abad, and Darabgherd. Behaban, near the boundary-line of Khuzistan, is situated on a very mountainous tract, but in an extensive and highly-cultivated plain: it is about three miles in circumference, and contains nearly 10,000 inhabitants. The mountains between this place and Shiras are nearly uninhabited. Kazerun, in a valley 30 miles long and seven or eight wide, was once a considerable place, but has been depopulated by civil wars. In 1809 it contained 3000 or 4000 inhabitants. Shiras,

the capital of the province, and for some time the residence of the kings of Persia, stands in a fertile plain, surrounded by extensive gardens. It is six miles in circumference, but a great part of the area is covered with ruins. The houses are generally small, and the streets narrow and filthy. None of the edifices are remarkable for antiquity or beauty, except the great Bazar, or Bazar-i-Wukell, which is a magnificent arcade nearly half a mile long and perhaps forty feet wide. It is constructed of yellow burnt brick and arched at the top, with numerous skylights, which, with the doors and windows, always admit sufficient light and air, whilst the sun and rain are completely excluded. It affords accommodation to several hundred shopkeepers. This town carries on a considerable trade with Yezd, Ispahan, and Bushire. Through Bushire it receives goods brought from India and Europe, which it exports to Yezd and Ispahan, receiving in return the manufactures of those two cities. The population is variously stated at 40,000 and 60,000. This place contains several manufactures of cotton, glass, iron, and gunpowder. The swords are made of steel brought from India, from the town of Lahore, and much prized, though less so than those of Khorasan and Kerman. The glass-houses are very extensive, and the manufactures are exported to all parts of Persia. The wine, made by the Armenians who are settled in this town, is thought to be equal to any in Asia. Shiras is also famous for its roses and the rose-oil which is obtained from them. Near the city are the tombs of the Persian poets Sadi and Hafiz. Firoze-abad, a town situated in a fertile plain, contains about 4000 or 5000 inhabitants. Darabgherd, a town containing from 15,000 to 20,000 inhabitants, is surrounded with groves of orange and lemon trees, and the juice of their fruit constitutes a considerable article of export to other parts of Persia. The tobacco cultivated here and at several other places in the neighbourhood is the best in Persia, and perhaps in the world. It is sent to distant places. North of this place is the pass of Ursinjan, which leads to Robat in Kerman, and runs for two miles between perpendicular mountains.

In no part of Persia is the number of ruins so great as in Farsistan. The most remarkable are those of Persepolis [PERSEPOLIS], which are situated north-east of Shiras, at a small place called Istekhar or Istakhr. The ruins of the antient town of Shapur are situated north-west of Kazerun, where they cover an area six miles in circumference, amidst rocks and precipices, many of which are decorated with sculptures similar to those near Persepolis. A statue from 15 to 20 feet high, now mutilated, is found in an immense cavern at Shapur. At Mourghab, 49 miles north-north-east of Istakhr, are other extensive ruins, resembling those of Persepolis, among which a building, called by the natives Musjed-i-Madre Solyman, is remarkable. It is considered by some persons to be the tomb of Cyrus the Great. [PASARGADÆ.] Near the great ruins of Persepolis are the Naksh-i-Roostan and the Naksh-i-Rejib, both of which are considered to be the tombs of kings of the Sassanian dynasty. Very extensive ruins occur in the neighbourhood of Firoze-abad. They occupy a large space in the plain, about 17 miles in length and half that distance in width, but have not been examined by European travellers. Other ruins of some extent occur in the neighbourhood of Darabgherd, and in several other places.

6. Laristan occupies the country between Cape Berdistan and the island of Kishm, and consists of the Dushtistan, or the low tract along the sea, and a hilly country. The low coast is in possession of the Arabs, who are subject to the iman of Muscat. The hilly country, which is about 100 miles in width, is sterile along the low plain, but seems to contain a great number of fine valleys, which produce dates and other fruits, and also grain. But as this country has seldom been visited by European travellers, we are very imperfectly acquainted with its capabilities. There are several small harbours on the Persian Gulf. The capital, Lar, is at the foot of a range of hills, in an extensive plain, which is covered with palm-trees. It contains about 12,000 inhabitants, and is celebrated for the manufacture of swords, muskets, and cotton cloth. The bazar is the noblest structure of that kind in Persia. It is built in the same manner as that of Shiras, but on a much grander scale, the arches being more lofty, the breadth and length greater, and the work in every way superior. The houses are commodious. The only water used is from large cisterns, in which it is collected during the wet season. Tarun, east-north-east of Lar, is as large and populous as Lar, but meanly built: it carries on a considerable commerce with Muscat, Gombroon, and Shiras.

7. Kerman occupies the south-eastern part of Persia, extending along the Persian Gulf from Cape Jask to a place opposite the island of Kishm, and thence northward to the borders of the desert, of which the adjacent southern part is considered as included in this province, and called the desert of Kerman. The desert is sandy and impregnated with salt, and here and there intersected by short rocky ridges. The remainder of the province, which extends more than 200 miles from south to north, but less from west to east, is nearly unknown, except the tract along the shores of the gulf, and another tract in the interior, between [illegible] and 30° N. lat. That part of the coast east of 57° E. long., which lies along the narrow entrance of the gulf, is extremely mountainous, and the rocks come close up to the sea, where they form a lofty coast. The short valleys in these mountains are well watered, afford pasturage all the year round, and contain fine plantations of date and other fruit trees. This is particularly the case where the coast runs south and north between the small town of Sereea and the large town of Mináb or Mináw. Between these two places the mountains retire from the shores, and thus a plain is formed which is very fertile; it is termed by the natives the Paradise of Persia. It abounds in every kind of fruit. The mountains then run northward, and form as it were a large gulf, retiring more than 50 miles from the sea, and then returning to it to the north of Bunder Abassi, or Gombroon. The plain thus formed rather resembles the sandy tract called Gurmsir than the country surrounding Minab, being sterile and producing nothing except dates. That portion of the Gurmsir which is within Kerman is subject to the iman of Muscat, who however pays a certain annual sum to the king of Persia. That portion of the interior of Kerman which has been visited by European travellers comprehends the Nurmanshir, a district about [illegible] miles in length, and from 20 to 30 miles wide, in which are several small towns, surrounded by large orchards and extensive cultivated grounds, and comparatively small sterile tracts. Two mountain-ranges enclose this district on the south and north. The southern range is of considerable elevation, and covered with snow during the greater part of the year. Between the Nurmanshir and the town of Kerman is a desert, with a few oases of moderate extent, and about the town itself there is a large tract of very fertile country. West of the town, to the very boundary of Farsistan, there are numerous rocky ridges, with difficult passes, and several large villages, with a good deal of cultivation round them. The town of Kerman, which was destroyed in the civil wars of Persia in 1794, still contains a population of 20,000 souls, of whom a small portion are Guebres: there are also Armenians, Jews, and Hindus. The trade is still considerable, and it is celebrated for its manufactures of shawls, matchlocks, and carpets, which are chiefly exported to Khorasan and the northern provinces, and in return for which are received drugs, skins (from Bokhara), furs, silk, steel, and copper. These articles, as well as pistachio-nuts, carpets, rose-buds, and bullion, are sent to India, from whence spices, cotton manufactures, broadcloth, china and glass wares, hardware, indigo, tin, lead, and iron are received. The bazar, which is extensive and well built, is abundantly supplied with articles of every description; and there are nine large caravanserais within the walls, and a number of inferior ones both within and without. In the unknown country between Kerman and the harbour of Gombroon, and on the road connecting these two towns, there is said to be a large place called Sultanabad. [GOMBROON.] Of Minab nothing is stated but that it is a large place with very commodious houses.

Opposite the town of Gombroon, and about 9 miles from it, is the island of Kishm, the largest in the Persian Gulf. It is 60 miles long, but the widest part does not exceed 12 miles. It is separated from the mainland by a narrow channel, which is very intricate, but navigable for the largest ships. It is stated that Kishm once contained upwards of 200 villages and towns, but they have been reduced to [illegible] that number. The inhabitants live by fishing and agriculture; and the island produces dates, wheat, and vegetables, with a few grapes, mangoes, and water-melons. There are two towns; Kishm, at the southern extremity, with [illegible] inhabitants, and Laft, on the northern side. At Bassadore, at the western extremity of the island, the East India Company had an establishment some years ago. Not far from Kishm is Hormuz. [Ormuz.]

8. Khorasan, or Khorassan, extends over a large part of the Great Desert, and over nearly the whole of the mountainous region which lies north of it. According to the Persian geographers, it once comprehended the whole of northern Persia as far as the neighbourhood of the Indus, and consequently nearly the whole of the country now subject to the king of Afghanistan. At present however its eastern boundary lies near 62° E. long., and even the town of Herat is subject to the Afghans, who however acknowledge that it belongs to Persia, and annually send a present to Teheran, as a sign of this acknowledgment. In that portion of the desert which lies between Herat and Yezd, numerous oases occur; most of them are small, but some are of considerable extent, and contain large towns. Among these towns are Gunabad with 30,000 inhabitants, Boshrewyah with 20,000 inhabitants, and Tubbus with a still larger population. Our information respecting these places has indeed only been obtained from natives, whose statements have usually been found to be very incorrect and exaggerated. But the wide valleys which lie between the desert and the declivities that form the descent from the table-land of Iran to the low sandy plains of Turan, must possess a considerable degree of fertility, as there are several large towns here, and the villages are numerous and populous, in spite of the frequent incursions of the Turkomans and Kurds. The latter were settled in a wide and very fertile valley which extends from the town of Mushed in a north-western direction for more than 100 miles, for the purpose of protecting the country against the invasion of the Turkomans; but they frequently themselves lay waste the most fertile portion of Khorasan. The most important town is Herat, the population of which is estimated at 45,000 by Conolly; it had been formerly stated at 100,000. It is built in a plain, which is 15 miles wide, 30 miles long, well watered, and covered with orchards, vineyards, fields, and villages. The city occupies an area of four square miles, and is encircled with a lofty wall and wet ditch. It forms a square, and has a gate in each side, and two in that which fronts the north. From each of the four principal gates a spacious bazar leads towards the centre of the town, where they terminate in a small square, which, like the bazars, is arched at the top. The town contains 1200 shops, 17 caravanserais, 20 public baths, many public reservoirs for water, and a great number of mosques. The manufactures are numerous, and supply carpets of wool and silk, and sword-blades, both which articles are used all over Persia. The commerce is very considerable, as the place is situated on the only great thoroughfare which leads from India to the western countries of Asia. The vicinity supplies some articles of commerce. Dry fruits and horses are sent to India, and to the western countries assafoetida, saffron, pistachio-nuts, mastic, manna, a gum called *birzund*, a yellow dye called *zyrsuch*, and carroway seeds. From India, Cashmere, Cabul, and Bokhara, shawls, indigo, sugar, chintz, muslin, leather, and skins are imported, most of which are re-exported to Mushed, Yezd, Kerman, and Ispahan; and from these latter places there are received in return, dollars, tea, china-ware, broadcloth, copper, pepper, and sugar-candy; dates and shawls are imported from Kerman. The shortest road from Herat to Teheran runs along the northern border of the Great Desert, and on it there are two places of importance, Toorbut (20,000 inhabitants) and Toorshish, but this road is not much used. The most frequented road runs from Herat in a north-west direction to Mushed, and thence westward through Nishapoor and Subzewar to Shahrood and Bostam. Mushed or Meshed occupies a larger space than Herat, but many of the houses are uninhabited and in ruins. The population amounts to 45,000, which however is often doubled by the number of pilgrims who visit the shrine of Imam Reza. A very wide avenue leads from the eastern to the western walls of the town, and is only interrupted by the tomb or shrine of Imam Reza. In the middle of it is a canal, and on both sides well furnished shops. The mausoleum is a magnificent building of great extent, and kept in good condition. A silver gate, the gift of Shah Nadir, opens into the chief apartment, which rises into a noble dome and branches out into the form of a cross. Neither Jew nor Christian is permitted to enter this building. The city has many mosques and sixteen medresses or colleges. There are also some manufactures; the most famous are those of steel, especially sword-blades. The silk manufactures also are of some importance; good velvet and some simple stuffs are made. A great number of persons are occupied with making jewellery, especially polishing and setting of turquoises for the pilgrims, who buy an immense number of them. Several utensils, as cups, plates, dishes, &c., are made from talc and exported. Mushed carries on a considerable trade with Bokhara, Balkh, Candahar, Yezd, Shiraz, Ispahan, and Herat. The town of Nishapoor, which was once a very large place, now contains only 8000 souls. In its neighbourhood are the famous turquoise mines, which are about 40 miles from the town towards the north-west. Subzewar contains about 1000, Shahrood 3000, and Bostam 4000 inhabitants. In the neighbourhood of these towns cotton is grown to a great amount.

The wide and fertile valley which runs from Mushed north-west, and is in the possession of the Kurds, contains some places of note. The largest is the town of Kabooshan, which contains from 15,000 to 20,000 inhabitants, and is the seat of the most powerful of the five chiefs of the Kurds. It has some commerce in wool, woollen stuffs, tallow, butter, and sheep-skins. Some distance east of the town is the celebrated fortress of Kelat Nadiree (the fortress of Nadir), which, according to the information obtained by Fraser from the natives, is in a valley from 50 to 60 miles long by 12 or 15 in breadth, surrounded by mountains so steep that a little assistance from art has rendered them quite impassable, the rocks being scarped into the form of a gigantic wall. A small river runs through this valley, and the only points of access occur where the stream leaves it; and even these are fortified by towers and walls, which are considered impregnable. The valley is well cultivated, and contains 2000 families in twenty or thirty villages.

9. Irak Ajemi, the largest of the provinces of Persia, comprehends a considerable portion of the Great Desert and the countries which enclose its north-western extremity on the west and north, and which in their different parts display a great variety of natural features. South of Ispahan (32° 30′ N. lat.), the mountains of Kurdistan terminate abruptly towards the table-land of Iran, and the country which lies between them and the desert, a space of more than 100 miles, consists of long and wide valleys running west and east and terminating in the desert. Little water is found in them, except after the melting of the snow, and only a small part of them is cultivated, though the soil seems rather fertile. North of Ispahan, as far as 30° N. lat., the Kurdistan mountains do not terminate abruptly, but between them and the plain there is a mountainous district, containing wide, fertile, and well watered valleys. East of this district extends a plain, about 40 or 50 miles wide, traversed by several broad and low ridges, and terminating on the border of the desert. It contains only a few cultivated tracts. That portion of Irak Ajemi which lies north of 35° N. lat. belongs to the table-land of Azerbijan: its surface stretches out in a plain consisting of gradual ascents and descents, and furrowed by deep valleys in which the rivers flow. Though nearly the whole of this province is destitute of trees, it has excellent pasturage and many well cultivated tracts. The surface is considerably higher than the plain farther east, and therefore the climate is not so hot in summer. The range of the Elburz mountains, with its well watered and fertile valleys, and its high summits, is included in Irak Ajemi, as well as the hilly country which skirts its southern base, and which is generally well cultivated, being irrigated by the rivers that descend from the southern declivity of the Elburz mountains.

That part of the desert which is included in Irak Ajemi contains an oasis of considerable extent, in which the town of Yezd is situated. The oasis has a sandy soil, and is mostly enclosed by mountains. But though it is sparingly watered, it produces much silk and fruit: the wheat that is raised is only sufficient for forty days' consumption, and large quantities of grain are imported from Ispahan. On the north, east, and south, the Great Desert spreads out to a great extent; but on the west, a series of small oases connect that of Yezd with the more fertile districts east of Ispahan. The town of Yezd is very large, containing about 8000 houses and 50,000 inhabitants, among which 3000 or 4000 families are Guebres, or fire-worshippers. These industrious people likewise constitute a great part of the population of the villages of the oasis. Yezd is remarkable as a commercial and manufacturing town. Its commercial importance arises from the caravan routes, which here cross one another. Two of these routes come from Herat and Mushed; two from the west, from Ispahan and Shiras; and one from the south, from Kerman. Thus this town is the entrepôt of the commerce between India, Turkistan, and the western countries of Asia. Its silk manufactures are more extensive than those of other towns, and a great variety of silk stuffs are manufactured. Though a considerable quantity of silk is grown in the oasis, still much is imported from Ghilan. Cotton is also manufactured to some extent, as well as carpets and felts; and much sugar-candy is made and exported. The summers are very hot, but the winters are cold. A good deal of snow falls, but it does not lie long on the ground.

Ispahan, or, more correctly, Isfahan, is still perhaps the most populous town in Persia, though much less so than it was in the time of Chardin, when it was the residence of Shah Abbas the Great, and was stated to contain between 600,000 and 1,000,000 inhabitants. At present the population is said to amount to between 100,000 and 200,000. It stands on the banks of the river Zeinderud, which during the heats of summer has little water, but in the spring months is equal to the Seine at Paris in winter. The mud walls are 24 miles in circuit. The streets are crooked, narrow and dirty, and unpaved, like those of most Persian towns. Ispahan contains a great number of magnificent palaces, large private buildings, spacious caravanserais, and handsome bazars, most of which however are now in a state of decay. On the southern side three nobly-constructed bridges cross the river; and near them, within the town, is a number of shady avenues of trees, which render that part of the city a very paradise, and lead to the great bazar of Shah Abbas. This extensive building is vaulted above to exclude the heat, but it admits air and light: it is now nearly abandoned. In a still worse condition is the Maidan Shah, or Great Square, which is 700 yards long and 200 wide, and enclosed by a double range of arched recesses. The houses in its vicinity are no longer inhabited, the very doors are built up, and a blank row of archways occupies the place where the most brilliant shops formerly displayed their wares. The other bazars are still partly crowded, but most of the numerous caravanserais have been converted to other and meaner purposes. The most sumptuous of the palaces is the Chehel Sittoon, with its hall of columns inlaid with mirrors so as to resemble pillars of glass. This building is situated in the centre of a garden, divided, according to the Persian fashion, into compartments by walks and canals bordered with poplars and stately chinars. There are also many other palaces, each with its own garden. Many of the mosques and medresses are in ruins; but a few of them are still in good preservation, especially the medress built by the mother of Shah Abbas, the gates of which are covered with wrought silver. Near the town is the suburb of Julfa, which is inhabited by Armenians, and contains a population of 12,500. The commerce of Ispahan with India, Bokhara, Shiras, Kerman, Bagdad, and Teheran is very great. The manufactures are various and numerous: in that of gold brocade it has attained unrivalled excellence.

The plain which extends from Ispahan to Teheran contains the towns of Kashan and Koom. Kashan is one of the most flourishing towns in Persia: it owes its prosperity to its manufactures of silk and cotton stuffs, brocades, carpets, and especially copper wares. It is as large as Shiras, but better peopled. Koom, which lies farther north, a large place, but almost entirely in ruins, was formerly celebrated for its manufactures of silk: at present it is only noted as a place of pilgrimage. Among the shrines of this sacred place, that of Fatima, the sister of Ali Reza, the eighth iman, is the most celebrated. Her tomb is in the centre of a lofty mosque, adorned with mosaic work in coloured tiles, and fitted up with rich carpets. The dome is covered with gilt tiles. There are some medresses, or colleges. In the mountainous country west of these towns are Khonsar and Hamadan. Khonsar is built in a long narrow valley, between steep and barren mountains, and is six miles in length, though not more than a quarter of a mile in width. It consists of isolated houses, surrounded by extensive orchards, and contains 2500 families. Hamadan is on or near the site of the antient town of Ecbatana. [ECBATANA.] North of Hamadan, on the table-land of Azerbijan, lies the town of Zenjan, a populous and thriving place, which derives its importance from being situated where the roads from Hamadan and Teheran to Tabriz meet. West of this town, near the boundary-line of the province of Azerbijan, or rather within the last-mentioned country, are extensive ruins, called Takht-i-Soleiman, which Major Rawlinson supposes to be those of the antient town of Ecbatana of Atropatene, or the Ecbatana of Dejoces. South-east of Zenjan, and at no great distance from it, is Sultaniyah, a town quite in ruins, in which the reigning royal family has built a palace, to which they retire when the heat in Teheran becomes oppressive. East of Zenjan is the famous pass of Rudbar, where the river Sefid-rud forces its way between the mountains of the Elburz and Massula ranges to the plain of Ghilan. It is more than 30 miles long, and the river dashes down between the rocks with incredible velocity. On the road from Zenjan to Teheran is Kazvin, or Casbin, one of the largest and most commercial towns of Persia, the population of which is differently stated at 20,000 and 60,000. It carries on a considerable commerce with Tabriz and Resht in Ghilan, and has manufactures of silk, carpets, and sword-blades.

Teheran, or Tehran, the present capital of Persia and seat of government, is situated on a plain about eight miles from the base of the Elburz range, in a country without trees, and only covered with verdure during the spring. The town is about four miles in circumference, surrounded by a strong and high mud wall flanked by numerous towers and a dry ditch. The streets are narrow and crooked; the houses are built of sun-dried bricks, and are mean, with the exception of a few palaces. The only building of consequence is the citadel, which contains the palace of the sovereign and his officers; but these buildings are much inferior in magnificence and beauty to the palaces of Ispahan. The population, which is rapidly increasing, varies according to the seasons. In winter and spring it may amount to 100,000, but when the king goes to Sultaniyah, it is diminished by one-third of that number. In the neighbourhood are the royal country-houses called Takht-i-Kujeriah and Nigaristan, and the ruins of Rai, the Rhagæ of the antients, and once the capital of the Parthian empire. The ruins consist of heaps of earth and rubbish, strewed with broken bricks and crockery. On these ruins is built the village of Shah Abdul Aazeem, which contains about 500 mud huts. About 70 miles east of Teheran, on one of the mountains of the Elburz range, is the fortress of Firuz-kuh, which is thought impregnable and of great importance, as it commands the principal and most accessible of the mountain-passes which lead over the range to the plain of Mazanderan. On the caravan route which leads from Teheran to Mushed are the towns of Semnoon, with from 4000 to 5000 inhabitants, and Damghan, with 2000 inhabitants.

10. Ghilan comprehends the western portion of the low plain which surrounds the southern shores of the Caspian Sea. It is the lowest part of the plain, and more subject to inundations and continual rains than Mazanderan, which lies farther east. During the greater part of the year it is properly a swamp, covered partly with forest-trees and partly with plantations of mulberries and rice-fields. There are no villages in this country, the peasants residing either in single dwellings or in small communities seldom exceeding eight houses. In some places there are bazars, which, as well as the small clusters of huts, are situated in the midst of the forests or plantations of mulberry-trees. Resht, the capital of Ghilan, one of the most commercial places in Persia, is situated in the midst of a forest at some distance west of the mouth of the Sefid-rud. The population is variously stated between 50,000 and 80,000. The houses are of a superior construction, and the streets generally well paved. Its commercial connections extend to Mushed and Herat, Teheran and Ispahan, and also to Badku and Astrakhan. There are several extensive manufactures of silk stuffs. The commerce with Astrakhan is carried on by means of the port of Enzillee, which is about [illegible] miles from Resht, and separated from it by a lagoon. The lagoon is from 30 to 40 miles long, from 12 to 15 wide, and from 8 to 10 feet deep, but shallower near the banks. It is separated from the Caspian Sea by a narrow and low sandy tract, which has a cut near the middle that serves as the entrance to the harbour of Enzillee. It is about half a mile long, about 500 yards wide, and 8 feet deep; but the bar which lies before it has seldom, except after north-east winds, more than 4 feet of water; and accordingly only small vessels, from 50 to 70 tons burden, can enter the harbour of Enzillee. This harbour lies on the west of the entrance, and is safe, being protected on the north by the narrow strip of land from the surf of the Caspian Sea, and on the south by an island. The town of Enzillee is a collection of

miserable huts, built on the south side of the narrow strip of land opposite the harbour. The population amounts to 2500. The goods to be shipped in this harbour are conveyed from Resht on horses to Peeri bazar, which lies on the banks of a small river, one of the feeders of the lagoon, and at that place they are embarked for Enzillee in boats. Lahijan is a neat well-built town, on an island formed by the bifurcation of the river Sefid-rud. It has a considerable commerce in silk with Resht and Ispahan. The population, according to Fraser, amounts to 15,000, but Monteith reduces it to 7000. The most northern portion of Ghilan is called Talish; the mountains which divide it from the table-land of Azerbijan are in possession of a tribe of mountaineers, who resemble in character and manners the Lesghis of Mount Caucasus, and are only nominally subject to the king of Persia.

11. Mazanderan comprehends the largest and widest portion of the low plain along the shores of the Caspian Sea. Though the country along the sea is very low and marshy, it rises somewhat at a short distance from the shore, owing to which circumstance the inundations produced by the heavy rains are less extensive and of much shorter duration, especially as the rains themselves are less frequent and less heavy, than in Ghilan. The climate is accordingly much more healthy, and several plants are extensively raised which do not succeed in Ghilan, especially the sugar-cane and cotton; but it does not produce so much silk as that province. It is however very well cultivated, and populous. Fraser compares the district between Balfrush and Amol with Bengal. The most western town in Mazanderan is Amol, mainly built on the western banks of a small river, the Herhaz, in a very irregular way, the houses being dispersed, and enclosed by orchards and groves. It contains from 35,000 to 40,000 inhabitants, and has some commerce in silk, the greatest quantity of silk collected in Mazanderan being grown in its neighbourhood. The river is navigable, at least during the greater part of the year, as far as the town for boats; the mouth does not form a harbour, but only some shallow lagoons. [AMOL.] Farther east is Balfrush, the most populous and commercial town in Persia, with 36,000 houses, according to Fraser. [BALFRUSH.] It carries on a very extensive commerce with Astrakhan and Badku, chiefly importing naphtha, which is used as lamp-oil all over Persia: also cloth, paper, hardware, gunpowder, leather, and iron: it gives in return the produce of the country, especially silk and sugar, with smaller quantities of rice, cotton, and timber; and also some articles obtained from the other provinces of Persia and from India. The river Bawul, on which it is built, is navigable for boats from the town to the mouth, where it forms a harbour for small vessels, and where there is a town of moderate extent. This town, called Mushed-i-Sir, is very thriving: it also contains the shrine of a saint. The river near its mouth is 60 yards wide, and from 12 to 15 feet deep, but a bar at the mouth prevents vessels from entering it. Russian vessels which visit the place are accordingly obliged to remain in the roadstead, the larger vessels at a distance of about one mile and a half, and the smaller of about a quarter of a mile. Saree is considered the capital of the province, being a very antient town and the seat of the governor. The walls, which are of mud, with square brick towers, are about two miles in circuit. The streets are unpaved, and often impassable in bad weather. The town contains a population of 30,000 or 40,000, and has some commerce with Astrakhan by means of its harbour Farah-abad, situated at the mouth of the river Tejen, which runs east of the town. At Farah-abad some Russians have established a very extensive fishery, as great numbers of sturgeons enter the river: they send caviar and isinglass to Astrakhan. At this place are the ruins of a large palace built by Shah Abbas the Great.

A great artificial road called *keyabun* was constructed by Shah Abbas the Great, through the provinces of Ghilan and Mazanderan. It begins at Kiskar, the western extremity of Ghilan, traverses the low plains of the provinces of Ghilan, Mazanderan, and Astrabad in their length, and ascends the declivity of the table-land of Iran by the pass which leads to Bostan in Khorasan, whence it is carried within a short distance of Mushed. In most parts it is still used, though it has been damaged in some places by torrents and inundations. It appears to have been 15 or 16 feet wide, and to have been constructed by filling a deep trench with gravel and stones, over which a regular causeway was very firmly built.

12. Astrabad comprehends the eastern portion of the low plain extending along the banks of the Caspian Sea, and the hilly country contiguous to it on the south. It is considered to extend to the banks of the river Attreck, but the country between that river and the Gourgan river, though of great fertility, is uncultivated and uninhabited, on account of the predatory incursions of the Turkomans, who wander about in the desert north of the river Attreck. In certain seasons of the year the Turkomans pasture their herds between the two rivers. The portion of the plain included in this province is in general higher above the level of the Caspian Sea than Mazanderan and Ghilan, and much less wooded. The fruit-trees succeed better, but the quantity of silk which is collected is not great. The climate, like that of Mazanderan, is unhealthy, though less so than that of Ghilan. For a description of its capital Astrabad see ASTRABAD. The commerce is not important. Every year one or two caravans, consisting of from 80 to 100 camels, go to Khiva and Urgendsh, but they are exposed to the attacks of the Turkomans, whose country they must traverse.

Manufactures.—The manufactures of Persia are numerous and of various kinds. All the towns, which once possessed a great population, and have not entirely fallen into decay, have preserved some branch of their numerous manufactures. But they have been much reduced, owing to the constant internal wars which laid waste the country for more than a century, and greatly diminished the population and wealth, and consequently both the power of producing and the means of purchasers. In the manufacture of some articles the Persians are still distinguished, as in several kinds of silk stuffs, especially brocades, and sword-blades, leather, carpets, felt of camel-hair, and jewellery. No machinery being used in the Persian manufactures, the cotton and silk goods lately introduced by the British have obtained a ready sale owing to their cheapness. The greatest number of manufactures are in the towns of Ispahan, Yezd, Herat, Tabreez, Kerman, Kashan, and Mushed. Those of the other towns are generally on a small scale.

Commerce.—The internal commerce of Persia is very considerable. The different regions which compose this extensive empire differ considerably in their natural productions, and the transport alone of commodities gives occupation to a great number of merchants and other people. To this must be added the produce of the manufactures, and the numerous articles which are brought into Persia from the neighbouring countries, especially from India, and are distributed all over the country. This commerce is entirely carried on by caravans. Though this mode of transporting merchandise is much more expensive than that in our country, it is the only mode which can be adopted in Persia, not so much owing to the want of roads, in which however the country is almost entirely deficient, as the impossibility of making them safe against robbers, and more particularly the predatory attacks of the wandering tribes. As the great thoroughfares generally pass within 20 or 30 miles of, and frequently on, the very border of the deserts, which are haunted by those tribes, single travellers would be subject to continual attacks from them, and thus all are obliged to unite in a caravan to secure their safety.

The most frequented caravan route runs on the northern side of the desert. By this road a great quantity of goods is brought from India and distributed over the northern parts of the country. It begins on the Indus at Attock, and runs up the Cabul river to Jillahabad, which is the starting-point of the caravans. Hence they pass to Cabul, and from Cabul in a south-western direction to Candahar, which direction they take to avoid the mountain region on the north, which is inhabited by the tribes of the Eimach and Hazarch. From Candahar they proceed chiefly along the base of that mountain region to Herat. At Herat the road divides. One branch runs west-south-west through several oases of the desert to Tubbus, and thence to Yezd. From the last-mentioned place it reaches Ispahan and Shiras. The other branch runs north-west to Mushed, and thence through Nishapoor to Shahrood and Teheran. Conolly gives us an idea of the extent of trade carried on by this road when he says, that the duties levied on the merchandise sold at Mushed amount to 15,000 tomans, or nearly 10,000*l.*, and according to this estimate, the whole amount of their value can hardly be less than half a million of English money. He enumerates also the articles, and indicates the countries from which they are brought, as from Ispahan and Yezd, fine velvet, silks, cotton-stuffs, felt, shoes, sugar, and candy-sugar; from Cashan, gold and silver, kimcob, cotton-socks, ink-stands, lamps of bronze, pots, and other utensils of copper; from Shiras, dates, tobacco, lemons, laquered-ware, ornaments made of ivory, and mats; from Kerman, shawls, candy-sugar, opium, henna, and indigo; from Sind and Hind, sugar, candy-sugar, spices, musk, amber, corals, precious stones, leather, kimcob, Indian and British muslins, and indigo; from Cashmire and Bokhara, shawls, saffron, paper; from China and Russia, by the way of Bokhara, lamb-skins (more than 120,000), stuffs made of camel-hair, tea, and Russian manufactures, as shagreen, broadcloth, satin, nankeen, china, glass, utensils of iron, copper, brass, cutlery, looking-glasses, needles, &c. Since the navigation on the Caspian Sea has increased, Russian goods are brought from Resht and Balfrush. From Herat are brought to Mushed, carpets, assafœtida, lead, saffron, pistachio-nuts, mastix, manna, gummi, ispiruck (a yellow dye), and caraway-seeds.

When the commerce of Gombroon was flourishing, a caravan-road led from that seaport to Kerman, and thence to Shiras, Ispahan, and Cashan, but that road is at present very rarely used. The great roads which lead over the mountains of Kurdistan from Teheran and Kazvin, either south-westwards through Hamadan and Kermanshah to Bagdad, or north-westward to Tabriz and thence to Erzerum and Sivas, are much frequented. A well frequented road leads also from Tabriz to Teflis in Georgia.

The foreign commerce of Persia is less important than the internal trade. Fraser, who had many opportunities of collecting information on that point, gives the following table:—

In the year ending May 31, 1821, the whole amount of exports from Persia to India at the port of Bushire, according to official reports, was stated at about . .	£305,000
That from Balfrush is estimated by the merchants there to be annually about 215,000*l*., but in order to include the whole remaining exports from Ghilan and Mazanderan, let it be stated at . .	250,000
Allow for exports from the smaller ports on the Persian Gulf, including the islands .	10,000
The commerce with Bagdad, which is considerable, particularly in silk, of which 12,000 maunds shohee are sent thither, may be taken at	200,000
That with the rest of Turkey, including a similar quantity of silk . . .	200,000
That with Teflis and Georgia . .	200,000
The exports to Bokhara and the states to the eastward	50,000
That with Arabia	10,000
	£1,225,000

According to this statement, Fraser finds that the exports of Persia are under a million and a half sterling. Though we think that nearly all his statements may be considered as approximations to truth, we must observe that he has omitted the exports to India by the way of Herat, and that he has also greatly underrated the exports of the places on the Caspian Sea, when he makes the exports from these harbours, excluding Balfrush, but including Resht, only amount to 35,000*l*. per annum. He himself states the export of silk from Ghilan to Astrakhan, in another of his numerous and instructive works on Persia, at 20,000 maunds shohee, and, according to his own statement, we must increase the second item of his list by at least 200,000*l*. The exports of Resht, besides silk, are rice, gall-nuts brought from Kurdistan, otter-skins, and cotton-cloth. The imports consist of iron, copper, hardware, looking-glasses, glass, cutlery, paper, tea, silver and gold wares from Moscow, and utensils of wood.

Government.—Persia is an absolute monarchy, in which the will of the sovereign is not, as in almost all the monarchical states of Europe, controlled and limited by institutions which have existed for a long time, and which cannot be infringed without exciting universal discontent. Institutions and a political order of this kind formerly existed, but they have been annihilated in the continual intestine wars which have desolated Persia during the last century. In Persia the word of the king is law, and the life and property of the subject are in his hands. He delegates his power to the governors of provinces, reserving to himself the power of life and death, with which he entrusts only the governors of the royal blood, and such persons as are sent to govern distant provinces or such as are in a state of rebellion. The governors of the provinces are called sardars, and those of smaller districts kulombegs. The tribes of the Iliyats however are not subject to these governors, but are under their own hereditary chiefs, who often pay very little respect to the orders of the king, whenever they think that they can do so with safety. The administration of the law is not exercised by the governors, but by courts. There are two different kinds of courts in Persia, the sherrah courts and the urf courts. The former decide matters according to the Koran and the traditional commentaries on it; the second, according to the customary laws of Persia. The limits between these two different kinds of law-courts are not fixed, but vary with the character and disposition of the sovereign. A sovereign of a strongly religious bias is inclined to refer all cases to the sherrah, while other sovereigns have tried to invest the urf courts with the chief authority. The supreme judge in the sherrah courts is the Sheik-al-Islam, who decides matters in the last instance, aided by the advice of the mooshteheds, or chief pontiffs. In every town there is such a judge, and in the larger ones also a cauzee, who is aided by a council of mollahs. The urf is administered by the king himself, and his governors and delegates. The courts are held in public, and the monarch sits for a certain time each day in his hall of audience, to hear appeals, to receive petitions, and to decide such cases as come before him.

The army of Persia consists of about 40,000 men regularly disciplined, of which only about 20,000 are organised on European principles. But the king can in a few weeks collect an army of 100,000 men, the greatest part of which number is supplied by the tribes of the Iliyats, and consists of irregular cavalry.

Language.—The history of the language of Persia, like that of the empire, may be divided into various periods, since, under each of the dynasties of which we have any remaining monuments, there was apparently a change in the dialect of the kingom. What this was in the infancy of the Persian empire is a point which, though often discussed, is far from being satisfactorily ascertained. Some say that the Zend and the Pehlvi were the two prevailing languages; the former being spoken in the north, the latter in the south. Others assert, not without foundation, that the Zend was not a vernacular but a sacred language, and that Zeratuhst, or Zoroaster, having composed in this language his book on religious and moral duties, entitled 'Zend Avesta,' two Pehlvi words which signify 'living soul,' the dialect in which that work was composed was called 'the language of the Zend;' while, if we are to believe Sir William Jones (*Works*, vol. iii., p. 113), who had it from a disciple of Zoroaster, *Zend* was the name of the character in which the books are written, and *Avesta* that of the language. [Zend.] Be this as it may, the Zend must have fallen into disuse at a very early period, being intelligible only to a few; since, in order to propagate the religious tenets of the *Zend Avesta*, the priests deemed it necessary to have the work translated into Pehlvi. It was undoubtedly extinct before the commencement of the vulgar æra, and we are told that among the *Guebres* of Guzerat, who still adhere to the doctrines of Zoroaster, there are few if any acquainted with it. As to the Pehlvi, so called either from the heroes or warriors who spoke it in former times, or from *Pahla*, the name for Media or Parthia among the natives, it was at first spoken nearly at the same time with the Zend, and attained to a high degree of perfection under the Sassanian kings. Indeed it was the common language of the nobility and the court, until, by the removal of the seat of the empire to the southern provinces, and the edict issued by Baharam Gour (A.D. 351), prohibiting the use of the Pehlvi in his dominions, that language gradually fell into disuse, and made way for the Parsi, or the idiom of Farsistan (Persis proper). This language, being more expressive and rich than the former, and being countenanced by the sovereign, and spoken by the courtiers, received the name of *Zeban Deri* (the language of the court), to distinguish it from that of the country where the Pehlvi and other rude dialects still prevailed under the generic denomination of *Zebán Parsi*. It has been lately asserted by an eminent philologist, Frank, that the Parsi is the mother of the Sanscrit; others, with Schlegel, maintain that the contrary is the case; but if we consider the greater simplicity of the Parsi, the former opinion seems the most probable. There can however be no doubt that the Zend, as well as the Parsi, has a common origin with the language of the Brahmans, while the Pehlvi is closely related to the Chaldee. Leibnitz has not hesitated to assert that the resemblance between the Teutonic languages and the Parsi was so great as to allow any German of education to understand at once whole Persian verses. After the conquest of Persia by the Arabs, Mohammedanism became the prevailing religion, and Arabic by degrees the language of the learned. At first it was cultivated for the purpose of reading the Korán. The addition not only of words, but of whole sentences, soon became a necessity, partly because words were wanting in Parsi to express many new ideas, and partly from an affectation of elegance, the Persian poets and rhetoricians striving to imitate the Arabian writers, whom they considered as their masters. The Arabic words thus introduced remained in some instances unchanged, or were merely altered in such letters as could not easily be pronounced; but in others they were changed and inflected according to the genius of the Parsi language. Thus was the modern Persian formed, which not only became general in all the provinces of Persia, but was also introduced into India by a descendant of Timúr, who founded the Mogul empire. But the old dialects of Persia were not entirely extinct. According to the reports of travellers, the Pehlvi is still spoken by the Buddars, a wandering tribe of Shirván, and by a few among the Guebres, or fire-worshippers; and some of the rude Kurdish dialects are considered to be pure Parsi. The modern Persian, though neither so rich nor so expressive as the Arabic, is more harmonious and better suited to all kinds of poetry. The prophet Mohammed was once heard to say that 'the language of Persia would be spoken in Paradise, owing to its extreme softness.' In the simplicity of its grammar it has been compared with the English; in its power of compounding words, with the German. The characters are the same as the Arabic, with the addition of four letters with three points. The Persian books are generally written in the sort of hand called *taalik*; although it is not uncommon to meet with works written in the *neskhi*, as the hand used by the Arabs is commonly called. Other systems or schools of writing seem to have been in use at various periods, such as the *Thuluth*, the *Rakaah*, and the *Tauki*, all of which however were founded upon the Arabic alphabet, and differed only in the shape of the letters.

To European students who wish to acquire a knowledge of the Persian language, the following elementary works may be recommended:—Sir William Jones, *Persian Grammar*, in the fifth volume of his *Works*; Gladwin's *Persian Moonshee*, Calcutta, 1801, in 4to. A new Persian Grammar, by Duncan Forbes and Sandford Arnot, Lond., 1828. Those of Lumsden and Richardson are also valuable works. In Germany, those of Dombay, Vienna, 1804, and Wilken, Leips., 1805-8, are most in use. Of Dictionaries we have, besides those of Meninski and Baretto, that of Richardson, reprinted by Wilkins, Lond., 1806, and the abridgment made by Hopkins, Lond., 1810.

Literature.—The literature of which the Magi were in possession, until the introduction of Islám, has scarcely anything to show in its old dialects, the Zend and the Pehlvi, but such parts of the books of Zoroaster as have been preserved, the commentaries upon the same, and the Persepolitan inscriptions, which are for the most part unintelligible. It is true, that during the reign of Nushirwán, surnamed 'the Just,' who lived at the close of the sixth century of the Christian æra, and was a liberal patron of literature, some works were written in the Pehlvi dialect, which were extant even after the time of Mohammed; but they have since perished. Of this number is a Pehlvi translation of a collection of moral fables, entitled the 'Fables of Bidpai,' which Barzuyeh, chief physician of Nushirwán, made from the Sanscrit by the orders of that monarch. [Bidpai.] Saad, one of Omar's generals, is likewise reported to have found in the tent of a Persian general, after the battle of Kádesiyyah, a history of Persia in the Pehlvi dialect, extracted from the annals of the Sassanian dynasty, and composed, it is believed, by the command of Nushirwán. As to the Deri or Parsi, after it became the language of the court, it was very much cultivated by the Sassanian kings and their vizírs, many of whom published works in it. Ardeshír Bábegán, the first prince of that dynasty, wrote the 'Kár-námeh,' or a journal of his achievements, as well as a work on morality, which was improved upon three centuries afterwards by Nushirwán. A vizír of this latter monarch, named Buzurj, wrote the '*Zefer Námeh*,' a work which is only known to us through the medium of a paraphrase made by the celebrated physician Avicenna (Ibn Sinnah), about the beginning of the eleventh century. During the first two centuries after the Mohammedan conquest, Persian literature was very little cultivated under the khalifs, who gave the preference to the Arabian. But when the power of the Abbásides began to decline, a number of independent princes arose in the different provinces of their empire, who vied with one another in promoting the cultivation of letters. The accession of the Bouyah family to the throne of Persia, in the tenth century, marked the great epoch of the revival of Persian learning. A sort of rivalship was then called forth by the fact of three contemporary princes, all lovers of letters, reigning at once in the provinces of Persia: Malek Shah Jelal-ed-din, king of Persia proper, of the dynasty of the Seljúkides; Kheder Ibn Ibrahim, sultan of the Ghaznevides; and Kheder Khán, king of Turkistan beyond the Gihon. To the united efforts of these three monarchs, and to their liberal encouragement of letters, the Persian literature may be said to have then been indebted for all its lustre. This flourishing state continued until the beginning of the thirteenth century, when the invasion of Genghis Khán gave a violent shock to all the arts of peace. Then came the invasion of Timúr-lenk in the fourteenth century; but that conqueror, far from discouraging polite literature, adopted the religion and the language of the country, and promoted the fine arts by his boundless munificence. The Turks themselves, who ravaged Persia during the ensuing century, greatly improved their harsh dialect, by mixing it with the language of that country, and one of their sultans, Mohammed II., who took Constantinople, is enumerated among the best lyric poets of Persia. In the sixteenth and seventeenth centuries, under the bloody reigns of the sultans of the house of Sefi, Persian literature sank to the lowest state; even the language was corrupted, and borrowed some of its terms from the Turkish, which was commonly spoken at court. Literature however seems to have somewhat recovered of late, if we are to judge from the works of Sheikh Mohammed Ali Hazín, which Belfour translated (Lond., 1830, 8vo.), and other writers of more modern times. We shall here give, from Sir William Jones, Von Hammer, and other authorities, a rapid sketch of Persian literature. Omitting however the numerous works on all subjects which fill the shelves of the public libraries in Europe, we shall confine our attention to a notice of those which are already known to Europeans either by extracts or translations. After Firdúsi, who wrote at the beginning of the eleventh century his celebrated epic poem entitled 'Sháh Námeh' (or book of kings) [Fir-

DUSI], came Ansarí, who has been called 'the king of poets,' and Asedí of Tús. In the same century flourished the celebrated Abú-l-ola, surnamed Alámí, from his blindness, who published some poems in which he professedly imitated the poets before Mohammed. Abú-l-ola left two disciples, Felekí, who wrote some excellent elegiac poems, and Ibráhím Khakání, who gained great reputation by his odes.

At the beginning of the twelfth century lived Anwarí [ANWARI], a native of Khorassán, and Reshidí Abd-el-Jelil, a native of Balkh in Khorassán. In the ensuing century, the city of Shiráz, which has not improperly been called the 'Athens of Persia,' gave birth to several distinguished poets. Of this number was the celebrated Sadí, who left behind him several works both in prose and in verse, the principal of which is entitled 'Ghulistán' (or bed of roses), a sort of mystic and moral poem, of which several editions and translations have been made. [SADI.] Contemporary with Sadí lived Feríd-ed-dín Attár, the author of a very valuable collection of proverbs, entitled 'Pendnameh' (the book of the council), a complete edition of which was published at Paris in 1819, under the superintendence of the late Sylvestre de Sacy, together with many others of his poetical works. Jelál-ed-dín Rumí, a native of Balkh in Khorassán, who died in 1262, is considered by the Persians as the most perfect model of the mystic school. His great work, entitled 'Mesnavi' (collection of distichs), is so difficult as to be scarcely intelligible without the help of a commentary. The city of Shiráz had also the honour of producing, in the fourteenth century, the most elegant lyric poet of Asia, Shems-ed-dín, surnamed Háfiz, whose works are sufficiently known to Europeans through the translations of Hindley, Rewiczsky, Jones, Von Hammer, &c. [HAFIZ.] Abd-er-rahman Ibn Ahmed, commonly called Nur-ed-dín Jámí, from Jám, his native city, the author of the 'Beharistán,' is also one of the most prolific and most pleasing of the Persian poets. To the same class belongs Abú Mohammed Nizámí, who flourished towards the close of the twelfth century, and is the author of five poems, three of which, 'Khosru va Shirín,' 'Leilah va Mejnún,' and 'Iskhander-nameh' (or the book of Alexander), are epic. Some tales and fables selected from one of his works, entitled 'Makhzen-al-asrar,' have appeared in the original and with an English translation in the 'Asiatic Miscellany,' Calc., 1786. Sheháb-ed-dín Abdallah Beyáni, surnamed Merwarídí, or 'the dealer in pearls,' owing to the sweetness of his versification, wrote a history of Shah Ismail, and a collection of odes and other poems, entitled 'Munis Al-ahbab' (the companion of the lovers), besides a metrical romance of Khosru and Shirin, which he left unfinished. He died in 1516. To the lyric poets of Persia belong also the Turkish emperor Selim I., the unfortunate Shah Allum, and Shah Feth Ali. Of less distinguished names, we might quote those of Khosru of Delhi, Abu Batta of Kermán, and Nání, by each of whom we have five long poems; Mir Ali of Shirván, Ahmed of Kirván, and the Amir Suleymán, each celebrated as the author of a history of Alexander (Iskhander-námeh); Sháhí, who was probably a pupil of Jámi, Hatefí, the emír Khosru, Senái, and Tefalí. The readers who wish to obtain information on the eminent poets of Persia and their works may consult the 'Beharistán' (or spring), by Jámí, some extracts from which were published in the 'Anthologia Persica,' Vindovonæ, 1778; the 'Kashfu-dh-dhanún' (or bibliographical dictionary) of Hájí Khalfah, now in the course of publication at Leipzig, with a Latin translation by Professor Fluegel; the 'Lives of the Persian Poets,' by Daulet Shah of Samarkand, and the continuation of Sám Mirza, entitled 'Tedhkirah ash-shoará' (see the extract from both in the 4th vol. *Des Not. et Ext.*); and lastly, the 'Ateskhede' (or temple of fire), by Loftali Beg, surnamed Azír.

The literature of the Persians abounds in prose fables and moral tales, mostly borrowed from the Indians. Of this class is a Persian translation of the fables of Pilpay, or Bidpai [BIDPAI], entitled 'Anwar-as-sohaylí.' Of the same kind is the 'Mufarraj-al-kolúb,' a version, or rather a paraphrase, of the Sanscrit Hitopadesa. Abú-l-fadhl, the vizir of the emperor Akbar, translated from the Sanscrit a collection of fables attributed to Vishnu Sarma, to which he gave the title of 'Iyár dánish.' The 'Bahar Danuch,' by Kinajut-ullah, was translated into English by Jonathan Scott, under the title of 'Garden of Knowledge,' Lond., 1799, 3 vols. 8vo. The same author published, in 1800, a collection of tales, anecdotes, and letters, translated from the Arabic and Persian. The 'Tootinameh' (or tales of the parrot), by Nakhshebí, were printed with an English version by Hindley, Lond., 1801, who translated likewise the 'Pendeh-i-Attar' (or counsels of Attar), Lond., 1809-14, 12mo. We have also the 'Bakhtyar Nameh' (or the story of Prince Bakhtyar and the ten viziers), by Sir William Ouseley, Lond., 1801, 8vo., Pers. and Engl. Langlés published likewise, in [illegible] his 'Contes, Sentences, et Fables, tirées des auteurs Arabes et Persans,' and Mr. Duncan Forbes has lately translated from the Persian a romance entitled 'The Adventures of Hatun Taï.'

In the department of history the Persians have produced some works which would do honour to any age or people. Mohammed Ibn Emir Khovend Shah, better known to Europeans as Mirkhond, wrote a work in several volumes entitled 'Ruzat-as-safá fi sirat al-Anbiya va-l-Moluk va-l-Kholafa' (or, the garden of purity, or the history of the prophets, kings, and khalifs), of which, besides the fragments given in Wilken's 'Chrestomathia Persica,' Leipzig, 1805, 8vo., several extracts have been published by Jenisch, Vienna, 1792. Jourdain (*Not. et Ext.*, vol. ix.) published in 1814, the history of the Ismaelites or Assassins of Persia, extracted likewise from the work of Mirkhond. De Sacy gave also a French translation of his history of the Sassanian princes in his 'Mémoires sur diverses Antiquités de la Perse' (Paris, 1793, 4to.); and Wilken published in Persian and Latin the history of the Samanides (Gött., 1808, 4to.). Lastly, our countryman Mr. David Shea has translated from the same sources, the 'History of Persia, from Kaiumars to the Death of Alexander the Great,' Lond., [illegible] 8vo. Mirkhond died in 1498. His son Khovend-mir Ghiyáth-ed-dín, commonly called Khondemir, who inherited his father's talents, wrote, besides the 'Kholassat-al-Akhbár' (or cream of the histories), a general history, entitled 'Habíbu-s-seyr' (the friend of the travellers), which, as well as the 'Ruzat-as-safá' by his father, was epitomised by Major David Price, in his 'Chronological Retrospect of Mohammedan History,' Lond., 1811-21, 4to. A translation of Tabarí's 'Chronicle,' a work of the greatest scarcity, in Arabic, was accomplished in the tenth century by Mohammed Balamí, a vizir of Nuh Ibn Nasr, the fourth of the Samanides. The first volume has been translated into French under the auspices of the London Oriental Translation Fund. The 'Lobb-tawárikh' (or marrow of history) by Yahya Ibn Abdallatif of Kazwín, who died in 1351, is also considered an excellent production. Abu Said Abdullah Al-beydawí wrote a universal history from Adam to his own times (A.D. 1276), entitled 'Nidhámu-t-tawárikh' (historical necklace), the eighth part of which, relating to China, was published in Persian and Latin by Müller, Berlin, 1677, 4to. Turán Shah, who died at Ormuz in 1377, wrote a 'Shah Námeh' (or book of kings), an abstract of which is given in the work of the Portuguese traveller Teixeira (*Relacion*, Amst., 1610). 'Matlaa-as-saadeyn' (the rising of the constellations) is a history of the kings of Persia of the family of Timúr, by an author of the name of Abd-er-razzák, whom Galland translated into French, but his version was never printed. Of Mohammed Kásim Ferishtá, an historian of the seventeenth century, we have a valuable work, part of which, on the history of Hindustan, was translated by Dow (Lond., 1768, 3 vols. 4to.), and part on the history of Deccan, by Jonathan Scott (Lond., 1794, 2 vols. 4to.). The entire work has since been translated by Major-Gen. Briggs (Lond., 1829, 4 vols. 8vo.), who has likewise published a lithographed edition of the original text. [FERISHTA.]

We are indebted to Sir William Ouseley for an epitome of the antient history of Persia, extracted and translated from 'Jehán Ara' (Lond., 1799), and to Gladwin for the 'Tuzuk-i-Jehánghir,' a very valuable work on the history and geography of Hindustan, attributed to the emperor Jehanghir. (*Asiat. Miscel.*) But by far the most important work on the history of India, written in Persian, is the 'Akbar-Námeh,' written, by the command of the emperor Akbar, by his vizier Abú-l-fadhl, who was put to death in [illegible]. The two first parts of this work contain a history of that sovereign and his predecessors; the third, entitled 'Ayeen Akbari' (or the institutes of Akbar), contains a geographical and statistical account of India, with much valuable information upon other interesting topics. An English version of the third part was published by Gladwin (Lond., 1777, 4to.; ib., 1800, 8vo.; and Calcutta, 1783-6). [AYEEN AKBERY.] There are also numerous works comprehending short periods of time, or the history of single dynasties and single reigns. The 'Tárikh Al-Mozaffer' contains a history of seven princes of the family of Mozaffer. Shah Baber, or Baber [Baber], the great-grandson of Timúr, left in the Mogul language some valuable commentaries respecting Hindustan, which were translated into Persian by Abd-er-rahim, and thence into English by Dr. Leyden and Erskine. Abd-er-razzâk wrote a history of Shah Rokh (Timúr's son) and his successors, as well as an account of his own embassy to China and Hindostan, a French translation of which has been inserted by Langlès in his 'Collection portative des Voyages' (Paris, 1797-1805, 8vo.). Mollah Sheref-ed-din Ali Jezdi, who died in 1446, wrote a biography of Timúr full of fables, which Petis de la Croix (François) translated into French (Paris, 1722, 4 vols. 12mo.). Sir William Jones published likewise a French translation of a history of Nádir Shah, written by his secretary Mirza Mohammed Mahadi Khân, who attended him in all his military expeditions. [Nadir Shah.] Gladwin translated a history of the same monarch, entitled 'Necessary Information,' by Abd-el-kerim of Cashmere, of whose pilgrimage to Mecca Langlès has given an abstract in his 'Collection.' A history of the same monarch, from Persian sources, was published by Fraser (Lond., 1742, 8vo.). Abú Tálеb Al-huseyni translated into Persian the 'Mulfoozat Timúry' (or institutes of Timúr), which this conqueror is supposed to have written himself in the Jagatai dialect. This work was first translated into English by White (Oxf., 1783, 4to.). It was then published in Persian and English by Stewart (Calcutta, 1785, folio); and lastly an English version by Stewart has appeared (Lond., 1830, 4to.).

In geography the Persians may be said to have derived most of their knowledge from the Arabs. They have a translation of the work of Ibn Haukal, an Arabian geographer of the ninth century [Haukal], as well as of the large work of the celebrated Kazwini, entitled 'Ajáyibu-l-makhlúkát' (the wonders of creation). They possess also a work entitled 'Heft Iklím' (seven climates), by Ar-razi; there is an English version of the first-mentioned work by Sir William Ouseley (Lond., 1800, 4to.). The same may be said of medicine. Geometry and astronomy seem however to have been cultivated by them with greater ardour. Násir-ed-din of Tús, the superintendent of the observatory and astronomical academy of Maragha, translated into Arabic the works of Euclid, which were afterwards commented upon by Mayrak Rashid. [Nasir-ed-din.] The latter author composed, at the command of Hulaku Ilekhan, the astronomical tables known by his name, but which were not completed until five years after that monarch's death (1263). Other tables were drawn up in the first half of the fifteenth century, by order of Ulugh-begh, which were afterwards published in Persian and Latin by Greaves and Hyde, under the title of 'Tabulæ Longitudinum et Latitudinum Stellarum Fixarum ex Observatione Vlug Beigi,' Oxon., 1665, 4to. A Persian calendar, under the title of 'Ruznameh nauruz,' was also printed in the collection entitled 'Vlug Beigi Epochæ celebriores,' Pers. et Lat., by Greaves (Lond., 1650). To the same class belong Bek's 'Ephemerides Persarum per totum Annum' (Vindobonæ, 1695, folio), and Welsh's 'Tabulæ Equinoctiales,' Augsburg, 1676, 4to.

The works on ethics are very numerous. We shall only mention the 'Akhlák-e-nasseri,' so called from its author Nasser-ed-din of Tus, a translation of which was lately announced by the Rev. G. Keene; and the 'Akhlák-e jelali,' published by the Oriental Translation Fund. The works on theology and jurisprudence are no less numerous. There is a Persian translation or abridgement of the Vedas, entitled 'Oupnekhat,' a French translation of which was published by Anquetil du Perron (Paris, 1804, 2 vols. 4to.). The 'Dabistan' was published at Calcutta, in 1811. The commentaries upon the Koran are chiefly in Arabic.

The Persians have paid great attention to their language, as the great number of grammars and dictionaries extant sufficiently shows. We might give the titles of many which have great reputation among the natives, but we shall merely notice the small Persian and Turkish dictionary of Shahidi, which however is only fit for beginners. That of Ardeshir has a higher reputation, as well as the 'Neamet-allah' (Grace of God), used by Castellus in the composition of the Persian part of his Lexicon Heptaglotton, Lond., 1669. But the most celebrated are the 'Ferhang Jehangiri,' by Jemal-ed-din Hossein Ibn Fakhr-ed-din, who dedicated it to the emperor Jehángir; the 'Ferhang Jewhari,' supposed to be a translation of the Arabic one, by Jouhari, which was published at Constantinople, in 1742; that of Seid Ahmed, printed at the same place, 1804; and the Persian dictionary, by the king of Oude, called 'The Seven Seas,' and published at Lucknow, in 1822, fol.

(Sir William Jones, *Works*, Lond., 1807; Sir William Ouseley's *Persian Miscellanies*, Lond., 1795; *Oriental Collections*, by the same, Lond., 1797; *Fundgruben des Orients*; *Notices et Extraits des MSS.*, &c.)

Religion.—Our knowledge of the religion of the antient Persians is principally derived from the 'Zendavesta,' or sacred books of the Persians, which were first made known to Europeans by Anquetil du Perron [Anquetil], and have been more fully explained and elucidated by Kleuker, Eugène Burnouf, Olshausen, Lassen, and other modern scholars. We learn from these books that the inhabitants of the antient Iran, which comprised Cabulistan, Sogdiana, Bactria, Media, and Persia, were originally one race of people, who spoke the same language and believed in the same religion. It was among them that Zerdusht, commonly called Zoroaster, arose, who must probably be regarded rather as a reformer of the antient religion than as the founder of an entirely new system. The time in which Zoroaster lived has been a subject of considerable dispute. Hyde and Kleuker suppose that he was contemporary with Darius Hystaspes; but others, with more probability, assign him a Bactro-Median origin, and suppose him to have lived long anterior to the time of Cyrus. But however this may be, his religious system became the dominant religion of Western Asia from the time of Cyrus to the conquest of Persia by Alexander the Great. Under the Macedonian and Parthian monarchies, the doctrines of Zoroaster appear to have been considerably corrupted by the introduction of foreign opinions; but on the re-establishment of the Persian monarchy by Artaxerxes in the third century of the Christian æra great exertions were made to restore the religion of the Persians to its primitive purity. The exercise of every other worship was strictly prohibited, and the religion of Zoroaster again became the dominant faith of the East, till the rise of the Mohammedan power, and the conquest of Persia by the Arabs in the seventh century, who compelled the greater number of the Persians to renounce their antient faith. Those who refused to abandon the religion of their ancestors fled to the deserts of Kerman and to Hindustan, where they still exist in the present day under the name of Parsees or Farsis, a name derived from Pars or Fars, the antient name of Persia. The Arabs call them Guebers or Khebers, which is derived from the Arabic *Káfir*, signifying an 'unbeliever.'

The principal doctrines of the religious system of Zoroaster may be explained in a few words. He taught the existence of an eternal, holy, and almighty being, who created two other mighty beings, and imparted to them as much of his own nature as seemed good to him. Of these, Ormuzd remained faithful to his creator, and was regarded as the source of all good; while Ahriman rebelled against his creator, and became the author of all the evil upon the earth. This doctrine of a good and an evil principle was the foundation of the whole religious system of the antient Persians. Ormuzd created man and supplied him with all the materials of happiness; but Ahriman marred this happiness by introducing evil into the world, and creating savage beasts and poisonous reptiles and plants. In consequence of this, evil and good are now mingled together in every part of the world; and the followers of good and evil —the adherents of Ormuzd and Ahriman—now carry on incessant war; but this state of things will not last for ever; the time will come, when the adherents of Ormuzd shall everywhere be victorious, and Ahriman and his followers be consigned to darkness for ever. [Ahrimanes.]

The religious rites of the antient Persians were exceedingly simple. They used neither temples, altars, nor statues, and performed their sacrifices on the tops of mountains. (Herodot., i. 131.) They adored fire, light, and the sun as emblems of Ormuzd, the source of all light and purity, but did not regard them as independent deities. The religious rites and ceremonies were regulated by a powerful sacerdotal class, called the Magi. [Magi.]

A full account of the religious usages of the Parsees of India is given by Herbert in his 'Travels,' and by Niebuhr. The practice of exposing the dead to be devoured by vultures, which is described by both of these travellers, agrees with what Herodotus (i. 140) says of the Magi, and also Strabo (p. 735, Cas.).

There are a few followers of the antient religion existing in the present day in Persia, but they are in a degraded and oppressed condition. Sir R. K. Porter remarks (*Travels*, vol. ii., p. 46), that 'from the restraints and fear under which they have been held for so many generations, both the doctrines of their faith and the most solemn rites of their worship have sunk into nothing more than a few hasty prayers muttered to the sun as supreme God: and what they call commemorative ceremonies are now only sad confused shadows of their former religious festivals.' At Bombay however the Parsees are a very active and rich class. They are in fact the proprietors of the greater part of the island. They are described by Lord Valentia (*Travels*, vol. ii., p. 174) as 'generous and splendid in the higher orders, and in the lower, active and intelligent, far surpassing as servants either Mussulmauns or Hindoos. They mostly speak English with propriety. In their persons they are a handsome race, fairer than the natives, though not possessing the clear skin of the Europeans. In their manners they are uniformly conciliatory and mild. They have numerous temples to fire, but their priests have no authority in temporal concerns, nor much spiritual control.'

(Hyde, *Veterum Persarum et Magorum Religionis Historia;* Rhode, *Die Heilige Sage der alten Baktrier, Meder, und Perser, oder des Zendvolks*, 1820; Gibbon's *Decline and Fall*, c. 8; Heeren's *Researches*, &c., 'Asiatic Nations,' vol. i., p. 366-392, Engl. transl.; Herbert's *Travels;* Niebuhr, *Reisebeschreibung nach Arabien*, &c., vol. ii.; Anquetil du Perron's, Kleuker's, Olshausen's, and Eugène Burnouf's editions of the *Zendavesta*.)

History.—The only credible and consistent account which we possess relative to the early annals of Persia is that derived from Grecian writers: for though a correspondence can perhaps occasionally be traced between these statements and the traditions of the Pishdadian and Kaianian dynasties preserved by Mirkhond and Firdusi, the incidents of the latter, and the marvellous exploits and length of reign (sometimes extended to three or four centuries) attributed to several of the monarchs, class them rather with mythological tales or romances of chivalry, than with the sober records of history. At the earliest period of which any trace is preserved, Persia appears to have formed a province of the great Assyrian empire, on the disruption of which it fell under the power of the Medes. Dejoces, the founder of the Median monarchy (about 709 B.C.), has been considered by some writers to be the Kai-Kaus of Oriental story: though others have held this name to be synonymous with Cyaxares, who, a century later, expelled the Scythians (or Trans-Oxian Turks) from Southern Asia. Astyages (Kai-Kobad?), the successor of Cyaxares, was dethroned (560) by Cyrus (Kai-Khosru?), who, according to Herodotus, was his grandson by his daughter Mandane, and who not only established the ascendancy of the Persians over the Medes, but by his victory over Crœsus, king of Lydia, which terminated (546) the dynasty of the Mermnadæ in Asia Minor, and by his conquest in 538 of Babylon and its dependencies, with Phœnicia, extended his empire to the Hellespont and the Syrian Sea. This great prince perished (529) in an expedition against the Scythians, probably beyond the Oxus; and was succeeded by his son Cambyses (529-21), who subdued Egypt. On his death the kingdom was usurped by a Magian, who personated Smerdis, the brother of the deceased monarch: but this impostor was destroyed by the nobles, who raised to the throne one of their own body, Darius Hystaspes (Gushtasp?). In his reign (521-485) the empire was divided into satrapies, and regular taxes introduced: Babylon revolted, and the walls were destroyed. And though a Persian expedition, under the command of Darius himself, against Scythia was a failure, the acknowledgement by Macedonia and Thrace of Persian supremacy extended the empire into Europe. The revolt of the Asiatic Ionians (501) and the aid given them by Athens, was the origin of the long wars of Greece and Persia. The defeat at Marathon (490) of a Persian force sent against Athens, showed the determination and military skill of the Greeks to be formidable; and hence resulted the famous expedition which, in 480, Xerxes, the son and successor of Darius (485-64), conducted in person against Greece. Herodotus states it to have consisted of above five millions of men, including an army of 1,700,000 infantry and 80,000 cavalry, and a fleet of 1200 ships. But this stupendous host, though it ravaged Attica and burnt Athens, sustained a signal naval defeat at Salamis: and the following year (479), after Xerxes had returned to Asia, the land and sea forces were discomfited in the two battles, fought on the same day, of Platæa in Bœotia, and Mycale on the coast of Asia Minor. The Persians were now driven from Europe; and Xerxes, who became more voluptuous and cruel after this disaster, was murdered by the captain of his guards (464).

During the long reign of his son Artaxerxes Longimanus (Ardashir Diraz-dast of Mirkhond, and probably the Ahasuerus of Scripture), the power of the empire greatly declined: the king was buried in the seraglio, while the distant satraps yielded only a nominal allegiance; Egypt was in continual revolt, and the Asiatic Greek cities were recognised as independent by the peace (449) which ended the Grecian war. The short reigns of Xerxes II. and Sogdianus occupy only a year (425): and the rule of Darius II., surnamed Nothus (424-405), presents only revolts at home and intrigues with Greece, where an alliance was formed with Sparta against Athens (411). Egypt threw off the yoke altogether in 414, and remained independent for sixty five years. Artaxerxes II., surnamed Mnemon, succeeded (405-359); and his younger brother Cyrus, attempting, at the instigation of their mother Parysatis (Peri-Zadah?), to dethrone him by the aid of an army of Greek mercenaries, was defeated and killed (401) at the battle of Cunaxa, in the plains of Babylonia, an engagement which was followed by the memorable Retreat of the Ten Thousand. In a war with Sparta, which commenced in 400, the integrity of the empire was threatened by the successes of Agesilaus, who, in three campaigns (396-4), advanced far into Asia: but by fomenting a coalition in the heart of Greece against Sparta, Artaxerxes was enabled, in 387, to conclude the advantageous peace of Antalcidas, by which Persia recovered the Ionian cities and Cyprus, though the latter was not reduced till after ten years' war. The accession of his son Ochus, or Artaxerxes III. (who confirmed his power by the slaughter of all his brothers), was followed by revolts in Asia Minor, Syria, and other provinces: but the former was betrayed by its leader Orontes, and Syria was reduced (351) by Ochus in person, who destroyed Sidon, and advancing into Egypt, expelled the king Nectanebus, and reunited that country to the Persian empire (350). After these successes, Ochus resigned himself to indolence and luxury, leaving the government in the hands of his favourite general, Mentor the Rhodian, and a eunuch named Bagoas, by the latter of whom he was poisoned in 338. Bagoas now placed Arses, the only surviving son of Darius, on the throne, but deposed and murdered him two years afterwards, when, the male line of the royal family being extinct, he invested Darius III., surnamed Codomannus (a great-grandson, by females, of Darius Nothus), with the vacant dignity. This prince commenced his reign (336-30) by ridding himself of the traitor Bagoas: but the invasion of his dominions by Alexander the Great, in 334, left him little opportunity for the exercise of sovereignty. By three great battles (Granicus, 334; Issus, 333; and Arbela, 331) the Persian empire was utterly overthrown; and the unfortunate Darius, flying from the arms of Alexander, was murdered (330) by his own servants, while the whole extent of his dominions from the Hellespont to the Indus fell under the sway of the Macedonian conqueror.

On the death of Alexander (323) and the dismemberment of his vast territories by his generals, Persia fell to the lot of the founder of the Syrian dynasty of the Seleucidæ, Seleucus Nicator (312-280), and remained in subjection during his reign and that of his son Antiochus Soter (280-61). But in the reign of Antiochus Theos (261-48), a germ of independence reappeared in the foundation of the *Parthian* kingdom in the country of Hyrcania (Deilem and Mazanderan) by Arsaces (Ashk?), the first of the house of the *Arsacidæ*, of which thirty monarchs reigned in succession, each bearing the title of *Arsaces*, in addition to his individual name. Arsaces I. reigned only two years (250-48), but his successor Tiridates I. (248-16) established his independence by defeating and taking prisoner (236) the Syrian king Seleucus Callinicus; and under Artabanus I. (216-196) this was confirmed by a treaty with Antiochus the Great. After the reigns of Priapatius (196-181) and Phraates I. (181-174), Mithridates, or Pacorus I. (174-136), extended the Parthian power to the Euphrates and the Indus, and, in 138, took prisoner Demetrius II. of Syria, who had invaded his territories; and the death of Antiochus Sidetes, who perished with his army (128) in an attack on Phraates II., deterred the Syrian kings from further aggressions. Phraates his successor Artabanus II. both fell in battle against the Trans-Oxians, or Turks; but these predatory hordes were repelled by Mithridates II., whose embassy to Sylla (92) was the first intercourse between Parthia and Rome. The reigns of Mnaskires (87-76), Sinatroces (76-69), Phraates III. (69-60), and Mithridates III. (60-54), were occupied by continual civil wars; but the sway of Orodes I. (54-37), who had dethroned and put to death his brother Mithridates, was distinguished by the first war with Rome, and the defeat and slaughter of Crassus with his legions on the plain of Carrhæ (53). In invading Syria and Asia Minor however, the Parthians were repulsed by Ventidius (39); but this defeat was avenged by Phraates IV. (B.C. 37, to A.D. 4) on Mark Antony, who only escaped from Parthia (36) with the loss of the greater part of his army. Some years later however Phraates opened diplomatic relations with Rome, and even sent his sons to be educated at the court of Augustus. The death of Phraates was followed by anarchy and dissension: Phraataces, Orodes II., and Vonones I. occupied the throne for short periods; and under Artabanus III. (14-44) the monarchy began rapidly to decline; the Romans even occupied the country for a short time, and proclaimed Tiridates, one of the Arsacidæ, as king; but Artabanus recovered his throne on the retreat of the Roman auxiliaries of the usurper. The reigns of Bardanes (Werdan?) (44-47), Gotarzes (47-50), and Vonones II. (50-52), contain nothing worthy notice excepting an unsuccessful attempt of the emperor Claudius to nominate a prince named Meherdates in place of Gotarzes; but under Vologeses I. (52-90) a long war with Rome was occasioned by disputes relative to Armenia, which were settled (65) by Tiridates, brother of Vologeses, accepting the Armenian kingdom as a fief of the Roman empire. The Roman alliance remained unbroken under Pacorus (90-107); but the reigns of Cosroes, or Khosru (107-121), Vologeses II. (121-149), Vologeses III. (149-191), and Vologeses IV. (191-209), were marked by almost continual wars with Rome. Ctesiphon, the capital of the Parthian empire, was taken and sacked by the emperor Septimius Severus in 199; and these contests, though they occasioned no loss of territory, greatly weakened the declining monarchy. Under Vologeses V. (209-16) civil wars were superadded to the attacks of the Romans; and his successor Ardwan, or Artabanus IV. (216-26), after maintaining himself for ten years against domestic revolts and foreign invasions, was defeated and killed, A.D. 226, in the last of three battles against Artaxerxes, or Ardeshir, surnamed Babegan, or the son of Babek, a native of Fars, or Persia Proper, who overthrew both the Parthian constitution and monarchy, and established, with the dynasty of the Sassanidæ, a new order of things in the East.

The erection of the *Sassanian* dynasty commences a new æra in the history of Persia (which antient appellation henceforward replaces that of Parthia), and from this period the native annals begin to supply comparatively authentic materials. The reign of Artaxerxes, or Ardeshir Babegan, after he attained undivided power (226-42), was occupied, excepting a short war with the Romans, in regulating his new dominions, and re-establishing in all its antient splendour the Magian faith, to the exclusion of all other religions; and his memory continued to be venerated as long as his descendants occupied the throne, both as the restorer of the Persian monarchy and religion, and as a legislator whose enactments and maxims of government were considered as the fundamental institutions of the country. His son Shahpoor, or Sapor I. (242-72), was a fierce and warlike prince, who conquered Armenia, and by his victory, in 260, over the emperor Valerian (who was taken prisoner, with his army, and died in captivity), taught the Romans to respect and fear the arms of Persia. Syria, Cilicia, and Cappadocia were laid waste with ruthless severity; Antioch was taken and plundered, but the latter part of his reign was less fortunate; Odenathus, prince of Palmyra, and his celebrated wife Zenobia, defied his arms, and Aurelian re-established the Roman frontier in the East.

The reigns of Hormuz or Hormisdas I. (273-4), of Varanes, or Bahram I. (274-7), Bahram II. (277-94), and Bahram III. (294), present no incident of importance except the unfortunate Roman war in the weak reign of the second Bahram, in which Persia was only saved from ruin by the sudden death of the emperor Carus. Narsi, or Narses (294-301), vindicated for a time the renown of the Persian arms by a signal victory (296) over Galerius; but in the next campaign the Persian forces were surprised and destroyed by the Romans, and, by the peace concluded in 297, Narses ceded Armenia and five provinces east of the Tigris. The reign of Hormisdas II. (301-9) was peaceful, but the long and splendid rule of his posthumous son and successor Shahpoor, or Sapor the Great (309-80), who was acknowledged as king even before his birth (Gibbon, ch. xviii.), revived the antient glories of the monarchy. His long war with the Romans (337-63) was contested with the whole force of the two empires, and with varied success. In the battle of Singara (348) Shahpoor triumphed over the emperor Constantius; and the invasion of Persia by his successor Julian, which threatened the dismemberment of the kingdom, was frustrated by the death of that prince and the cowardice of his successor, who purchased a safe retreat by the peace of Dura (363), which restored Armenia and all the cessions made by Narses, with the impregnable fortress of Nisibis. The wisdom of Shahpoor in government was equal to his valour in war; and the kingdom continued in peace and prosperity throughout the reigns of the next three monarchs, Artaxerxes or Ardeshir II. (380-85), Shahpoor III. (385-90), and Bahram or Varanes IV., surnamed Kermanshah (390-401), the founder of the city of that name. Yezdejerd I. (Isdigertes) engaged in no foreign wars, but his reign (401-21) was disturbed by religious dissensions: the Magi murmured at the toleration and favour shown by the king to the Christians, and his friendship for the Greek emperor Arcadius gave rise to the fable that the latter entrusted to him the guardianship of his son Theodosius; but the persecution of the Christians with which his son Bahram V., surnamed, from his love of the chase, Gour, or 'the Wild Ass,' commenced his reign, led to a short and indecisive war with the Romans. The subsequent sway of this prince was glorious and popular; after repulsing with great loss an invasion of the Turks of Trans-Oxiana, he extended his realm to the frontiers of India; and his extraordinary personal prowess has preserved his memory to the present day in Persia as a favourite hero of romance. He perished accidentally in hunting, leaving the crown to his son Yezdejerd II. (surnamed Sipah-Dost, or, the 'Soldier's Friend'), whose reign of sixteen years (442-58) was a period of peace and prosperity. On his death, his younger son Hormuz III. mounted the throne, but was speedily expelled by his elder brother Firouz, or Peroses, who had been furnished with an army by the Khan of the White Huns, or Turks of Trans-Oxiana. Firouz however returned this service by attacking the dominions of his benefactor: in his first invasion he was defeated and taken prisoner, but released by the generosity of the Khan. In a second attempt the Persian army was cut to pieces, and their perfidious king left among the slain, after reigning twenty four years (458-82). His son Palash, the Valens of the Greeks, reigned only four years; but his brother and successor Cavades, or Kobad (486-531), though his addiction to the libertine tenets of Mazdak cost him a four years' dethronement (497-501) in favour of his brother Jamasp, eventually retrieved the kingdom from the vassalage to the Huns, in which the fate of Firouz had left it, and waged a successful war with the Greek emperor Anastasius; and his son, the illustrious Khosru Nushirwan (531-79), raised the Sassanian empire to its highest pinnacle of grandeur and prosperity. For the details of his long and glorious reign we refer to the article KHOSRU. He carried his arms to the Mediterranean, the Euxine, the Sutlej, and the Jaxartes. Trans-Oxiana, the Punjab, and great part of Arabia, obeyed his mandates. Persia was divided into four great vice-royalties, and the excellence of the internal administration, in which the king was aided by his celebrated minister Buzurg-Mihir, has earned for him the proud appellation of 'Just.' But the last years even of Nushirwan were clouded by reverses, and his unworthy son Hormuz (579-90), after losing all the conquests of his father, forfeited his throne and life in a popular revolt headed by Bahram-Tchoubeen, a general who, after saving Persia from the Turks, had been basely disgraced by the king. Bahram attempted to ascend the throne, but Khosru *Perwiz*, son of Hormuz, easily recovered his inheritance (590-628) by the aid of the emperor Maurice, on whose dethronement and death (602) Khosru attacked the Roman empire, under the pretence of avenging his ally, and in sixteen years restored the Persian empire to the limits under Xerxes, by the conquest of Syria, Asia Minor, and Egypt; but these successes were transient, and Khosru, after having been in turn driven from his palaces by the victories of Heraclius, was murdered by his own son Shirouyeh or Siroes. The parricide survived his father only six months, and in four years of confusion and civil war the throne was filled by six kings and two queens, till the accession of Yezdejerd III., in the same year (632) in which Persia was attacked by the Arabs, then commencing the career of Mohammedan conquest. The fate of the kingdom, weakened by internal dissensions, was decided by the battles of Cadesia (636) and of Nehavend (641), the last of which, though the king survived in the condition of a fugitive ten years longer, subverted at once the Sassanian power and the independence of the country.

For more than two centuries after the Mohammedan conquest, the national history of Persia presents an entire blank. The Persians imbibed the religion and literature of the Arabs, to whom they imparted in return their civilization and luxury; but the country was only a province in the empire of the caliphs, and followed implicitly the revolutions of the Ommiyades and Abbasides. [ARABIA; ABBASIDES; MOORS.] But with the decay and division of the power of the Commanders of the Faithful, the spirit of independence revived, and the re-establishment of the kingdom may be dated from the foundation of the *Soffarian* dynasty by Yakub Ibn Lais, who about 868 threw off his allegiance to the caliph, and fixed at Shiras the capital of a dominion including nearly all Persia. But his brother and successor Amer was subdued, in 900, by the Tartar family of the Samanides, who ruled Khorassan and Trans-Oxiana till 999, while Western Persia again acknowledged for a few years a precarious allegiance to the caliph, till the utter disruption of the Abbaside power threw it, about 936, into the hands of the three sons of Bouyah, Amad-ed-doulah, Rukn-ed-doulah, and Moazz-ed doulah, who shared the kingdom among them; while the last-named occupied Bagdad, and exercised, under the title of Emîr-al-Omarâ, absolute control over the person and remaining territory of the caliph. After the death of Amad-ed-doulah, nearly all the dominions of the *Bouyah* (sometimes called *Deilemi*) dynasty were reunited under his nephew or successor Adhad, or Azed-ed-doulah, one of the greatest and most virtuous princes of his time, whose reign of thirty-four years (949-82) is the æra both of the grandeur of his family and of the prosperity of Persia. His successors again divided the kingdom, and wasted their strength in internal dissensions, during which a number of petty principalities rose to independence. One principal branch of the Bouyahs continued however to retain Bagdad and the dignity of Emîr-al-Omarâ, raising and deposing the pontiff-caliphs at their pleasure; but the other, which ruled in Eastern Persia, was subdued, in 1028, by Mahmood, who thirty years earlier had founded the mighty dynasty of the Ghaznevides in Cabul and Khorassan, on the ruins of the Sassanian power, and had carried the Moslem arms, for the first time, into the heart of India. All Persia seemed on the point of falling into the hands of this conqueror and his family, when the prize was snatched from their grasp by the descent from Central Asia of the *Seljookian* Turks, who, originally received as vassals by the Ghaznevide princes, soon asserted their independence, and after defeating Massood, the son and successor of Mahmood, A.D. 1040, in a great battle near Nishapur, compelled the Ghaznevides to confine themselves to Afghanistan and their Indian conquests, and placed their own sultan, Togrul-Beg, in possession of Persia, to which (1055) he added Bagdad and Irak, with the guardianship of the caliphate, deposing the Emîr-al-Omarâ Malek-Raheem, the last of the house of Bouyah. The reigns of Alp-Arslan, the nephew and successor of Togrul (1063-72), and his son Jelal-ed-deen Malek Shah (1072-92), raised the Perso-Turkish monarchy to the highest pitch of splendour and glory. [ALP-ARSLAN.] The Greek emperor Romanus was defeated and taken, and Armenia subdued by Alp-Arslan: the rule of his son extended over great part of Syria, Arabia, and Tartary, while internal prosperity was secured by the wise administration of the famous vizier Nizam-al-mulk; and the reformation of the calendar, by the establishment of the Jelalæan æra (March 15, 1079), shows that the progress of science kept pace with that of conquest. But the unity of the empire was dissolved at the death of Malek Shah: his sons divided and disputed the provinces of Persia; minor branches ruled in Kerman, Anatolia, and Syria; and when Sandjar, the youngest and most warlike of the sons of Malek Shah, succeeded, about 1120, in establishing his own supremacy over most of the eastern parts, the provinces of Azerbijan, Fars, Laristan, &c., were virtually independent under petty princes bearing the Turkish title of *atabek*, who, from being lieutenants of the sultan, had aspired to hereditary rule; while in the mountain country immediately south of the Caspian, the infamous sect of Ismailis, or Assassins [ASSASSINS], had subsisted from the time of Malek Shah. After the death of Sandjar (1156) civil wars recommenced among the Seljookian princes, of which the caliphs availed themselves to recover from them the exclusive possession of Bagdad and and Irak; and though Togrul III. reunited (1175) the remaining provinces, he was overwhelmed and slain (1194) by Takash, shah of Kharism, a former dependency of the Seljookian empire, the viceroys of which had thrown off their allegiance during the reign of Sandjar, and had gradually subdued Trans-Oxiana and Khorassan. Persia now fell under the yoke of the Kharismian sultan, who by the destruction, a few years later, of the Ghaurides (a dynasty which had supplanted the Ghaznevides in Cabul), extended his sway from the Caspian and the Sea of Aral to the Indus and the Persian Gulf. But this mighty power was of short duration: Mohammed, the successor of Takash, became embroiled, through the misconduct of the governor of Otrar, with the ruler of the Moguls beyond the Jaxartes, the redoubtable Gengis-Khan, who in 1218 invaded his dominions with a host of 700,000 men, and in two campaigns drove Mohammed to take refuge in an island of the Caspian, where he died in 1220. His son Jelal-ed-deen Mankberni, a celebrated paladin of Eastern story, maintained for some years a gallant but unavailing struggle, till his death, in 1230, finally dissolved the Kharismian power, and laid Persia prostrate at the feet of the Moguls.

The conquest of Persia by the Seljookian Turks had been softened by their community of faith and their speedy adoption of the manners of the south, but the Moguls detested and despised alike the Moslem faith and the refinements of civilization, and their progress was everywhere marked by merciless slaughter and devastation. On the death of Gengis, Persia fell to the share of his grandson Hulaku, who, in 1258, took and sacked Bagdad, putting to death the last of the Abbasides, and massacring, according to Persian historians, 800,000 inhabitants of the city. The dynasty of *Hulaku* ruled Persia about eighty years. Abaka, his son and successor (1264-82), extended his authority over the Seljookian princes of Anatolia, and formed alliances with the Christians for the recovery of Syria and Palestine; but his armies sustained several signal defeats from the Mamelukes, and of the short reigns which follow, that of Key-Khatu also deserves notice for an unsuccessful attempt (1294) to introduce into Persia a paper currency, which already existed in China. The invasion of Syria was renewed, but again without success, in the reign of Ghazan (1295-1303), who first threw off the nominal allegiance which his predecessors had hitherto paid to the grand khan of Tartary, and embraced, with all his subjects, the Moslem religion. His brother and successor Aljaptu, or Mohammed Khoda-bandah (1303-1[illegible]), founded the celebrated city of Sultaniyah, which he made his capital; but the hereditary Mogul nobles were gradually absorbing all the power of the state, and Abou-Said Bahadur, the son of Aljaptu, and eighth in succession from Hulaku, was the last of his race who enjoyed any authority, though several pageant monarchs were afterwards elevated for short periods. Persia was now divided and distracted by numberless petty dynasties, perpetually at war with each other. The Il Khanians, who possessed Bagdad, Irak, Azerbijan, &c., were perhaps the most powerful of these princes, while the Modhafferians ruled over Fars and Shiras; the Sarbedarians, Molouk-Kurt, &c., occupied Khorassan and the neighbouring parts; and hordes of marauding Turkomans, the origin of the present clans of Persia, roamed over the country, uncontrolled by any [illegible] rulers.

Such was the state of Persia when a new conqueror appeared from Tartary, in the person of the famous Timur-lenk, or Tamerlane, who speedily involved all the contending parties in one common ruin. Already master of Trans-Oxiana and Tartary, he invaded Khorassan, in 1381, at the head of a force which produced the instant submission of all the petty princes in that quarter; and in twelve years from this time, though frequently recalled into Tartary to repel the attacks of the khan of Kipzak, he had subdued and devastated the whole of Persia, meeting with little determined resistance except from the gallant Modhafferian prince of Shiras; his overthrow was followed by the slaughter ([illegible]) of 70,000 inhabitants of Ispahan, whose heads were piled in pyramids by order of Timur; and Bagdad, though saved the first instance by the submission of the people, who refused to defend their tyrannical sovereign Ahmed Il-Khani, shared a similar fate in 1401, as a punishment for its revolt against Miran Shah, the son whom Timur had left to govern Persia. The pursuit of some of the Turkoman tribes brought him in contact with the Ottoman Sultan Bayazid; but his victories over the Turks and the Mamelukes of Syria do not come within the scope of this sketch. He died near Otrar, in 1404, as he was on the point of setting out for the conquest of China: his empire, upheld only by the terror of his name, fell to pieces almost instantly, and Persia, in a few years after his death, had relapsed into a state of division and anarchy even worse than that which had preceded his irruption. His son Shah Rokh indeed, who ruled over Khorassan, Trans-Oxiana, and Tartary (1409-46), exercised during his life a paramount authority over great part of the country, and more than once repressed in arms the depredations of the Turkomans; but the sway of his descendants was limited to Trans-Oxiana and Eastern Khorassan, which they held till expelled by the irruption of the Uzbeks at the end of the century, while the western provinces were contested by two races of Turkomans, distinguished by their emblems of the *black* and the *white sheep*. Kara Yusef, the founder of the former race, had been an antagonist of Timur, after whose death he attained considerable power (1407-20); but his successors wasted their strength in domestic quarrels, till they were overwhelmed and extirpated (1469) by Uzun Hassan, or Hassan the Tall, ruler of Diarbekr, of the *white sheep* dynasty. Uzun Hassan was a wise and valiant prince, and succeeded in making himself master of the greater part of Persia; but, encountering the superior power of the Ottoman Sultan Mohammed II., he sustained a signal defeat in Anatolia (1473). He was nevertheless preparing to enter into a league with Venice, the Rhodian knights, and the sultan of Egypt, against the preponderating power of the Porte, when death put an end to his projects (1478); and his relatives and descendants, after disputing for several years the possession of his extensive territories, were finally supplanted and crushed (1502) by the first of a race of sovereigns whose character and rule imparted to the Persian monarchy a greater degree of stability and more settled forms of government than it had for some centuries enjoyed.

Ismael Shah, the founder of the *Sefi, Sooffee, or Seffaveean* dynasty (whence the common appellation of *Sophi*, applied to a Persian monarch), was remotely descended from the caliph Ali, the cousin and son-in-law of Mohammed, and more immediately from a race of ancestors whose hereditary reputation for sanctity was of great service, both in his own ascent to the royal dignity and the subsequent long retention of it by his family. From the red cap which he introduced as the distinctive head-dress of his people, the Persians derived the epithet of Kuzzil-Bash (Red Heads), by which they have been ever since known; but their adhesion at this period to the Sheah or heterodox sect of Islam has been the origin of their national enmity to the Turks, who hold the Sooni or orthodox persuasion. The greater part of his reign (1502-24) was employed in the reduction of the various provinces of his kingdom. By a great victory, in 1510, over the Uzbeks, he stopped their career of conquest, and confined them to the other side of the Oxus; but he sustained a severe defeat, in 1514, from the Turks under Selim I., though he subdued Georgia a few years later. The long reign of his son Tahmasp I. was occupied principally by wars against the Uzbeks and Turks, the latter of whom several times invaded Persia, and once penetrated to Ispahan; but the boundaries of the two empires were fixed, in 1555, by a peace which has been the basis of all subsequent treaties. The embassy of Anthony Jenkinson (1562) was the means of opening commercial relations between England and Persia; but the chief glory of Ismael's reign, in the estimation of Oriental writers, was the munificent hospitality which he extended to the Mogul emperor Humayoon, when driven from India by a rebellion. The reigns of Ismail II., son of Tahmasp (1576-7), and his brother Mohammed Khuda-bundah (1577-85), present nothing worthy of note except the renewal of the Turkish war; but under the rule of Abbas the Great, son of Mohammed (1585-1627), the Seffaveean dynasty attained its zenith of power and renown. [ABBAS.] After totally expelling the Uzbeks from Khorassan, in the first part of his reign, he turned his arms against the Turks, over whom (having equipped, by the aid of two English travellers, the brothers Shirley, a corps of 12,000 musketeers) he gained repeated victories from 1602 to 1618, in which year a peace was concluded, restoring to Persia all her former possessions. In order to promote manufactures, he invited Armenian artificers to settle at Julfa, and formed an alliance with the English, by whose aid he expelled the Portuguese from Ormuz; he removed the capital from Kazwin to Ispahan, and greatly improved the internal communications of the kingdom; but in his old age he grew suspicious and cruel, and his last years were embittered by regret for the loss of his eldest son, whom he had unjustly put to death. His grandson and successor Shah Soofi I. (1627-41), was a cruel and drunken tyrant; the warlike Ottoman sultan, Mourad IV., availing himself of his incapacity, recovered most of the Turkish losses, and took Bagdad in 1637, after which a peace was concluded, restoring the boundaries as in 1555, and giving up the acquisitions of Abbas the Great.

The reign of Abbas II. (1641-66), and his son Soliman or Shah Soofi II. (1666-94), are almost destitute of events in their foreign relations, which continued uniformly peaceful. Commerce and the arts flourished during this period; many European travellers, as Tavernier, Kæmpfer, Chardin, &c., visited Persia, and embassies from many foreign powers appeared at Ispahan, particularly a splendid mission, in 1672, from Louis XIV. of France; but the court was sunk in indolence and luxury, and the warlike spirit of the people had greatly declined from inaction. The first part of the reign of Shah Sultan Hussein (1694-1722) passed also in tranquillity; but this was only the calm which precedes a storm. The character of the king, a weak and bigoted though amiable prince, surrounded and governed by mollahs and eunuchs, promised impunity to revolt or aggression. Georgia, Laristan, and other remote provinces rebelled and were reduced, but the revolt of the Afghans of Cabul and Candahar, in 1709, had more formidable consequences. Their chiefs, Meer-Weis and his successor Meer-Mahmood, repelled with loss all the attacks of the Persians; and in 1720 Meer-Mahmood, encouraged by the spectacle of weakness which the monarchy presented, invaded the country with 25,000 men; and in 1722, after routing the Persians at Goolnabad, under the walls of Ispahan, invested the capital, which, after enduring for several months all the horrors of famine, was forced to capitulate. Hussein resigned his crown to the conqueror, placing the royal aigrette with his own hands in the turban of Mahmood, October 23, 1722; and Persia, after having been ruled 220 years by the family of Ismael Sooffee, thus fell under the yoke of the Afghans.

The crown-prince Tahmasp however held out in Armenia, and Russia and the Porte, taking advantage of the confusion which prevailed, formed the design of dismembering Persia by seizing the districts adjoining their own territories. A partition treaty was concluded for this purpose, and Tahmasp, in 1723, actually ceded the Caspian provinces to Russia, in return for a promise of aid, which was never fulfilled; while on the other hand Meer-Ashraf (the cousin and successor of Mahmood, who died raving mad in 1725) gave up, by the peace of Bagdad (1727), Azerbijan, Khuzistan, and Irak to the Turks, who in return acknowledged him king of Persia. But the progress of Tahmasp and his great general Nadir-Kooli was fast destroying the brief tenure of the Afghans in Persia, though they strove to maintain it by dreadful massacres of the nobles and disaffected citizens. Ashraf was driven from Ispahan by Nadir, in 1729, and killed, after a second defeat, in 1730. The invaders were everywhere exterminated, and Shah Tahmasp re-occupied Ispahan. But all the real power remained in the hands of Nadir, who in 1732 dethroned Tahmasp for concluding an ignominious peace with the Porte, elevating his infant son Abbas III., in whose name he governed as regent, and after expelling the Turks from their conquests, concluded a peace in 1736, re-establishing the ancient frontiers of Turkey and Persia, while the districts ceded to Russia were recovered by treaty. Abbas died the same year, on which Nadir formally declared the Seffaveean dynasty at an end, and himself assumed the crown under the title of Nadir Shah.

This extraordinary man raised Persia, for a short time, to a higher degree of power than she had possessed since the rule of the Sassanian kings. He conquered Candahar and Afghanistan; and in invading India, in 1739, took Delhi, and carried off a booty estimated at 32,000,000*l.*, reducing the next year the Uzbeks of Khiva and Bokhara, long the enemies of Persia. A second war with the Porte (1743-6) terminated favourably to Persia; but the barbarities and avarice of Nadir exasperated his subjects, and he was murdered in his tent, 1747. [NADIR SHAH.] His death was the signal for a scene of anarchy and confusion; the Uzbek states threw off the yoke, and Afghanistan became an independent and powerful kingdom under Ahmed Doorauni, while the crown of Persia was contested by various competitors, and the kingdom torn by civil war, till a chief named Kereem Khan, of the Zend family, succeeded, in 1759, in possessing himself of supreme power, which he held till his death, in 1779, under the title of Wakeel, or Administrator, refusing the insignia of royalty. His sway was mild and equitable; he repressed the depredations of the Turkoman tribes which, under Nadir, himself a Turkoman and a Sooni, had overspread Persia; and he concluded advantageously a short war with the Porte. But fresh troubles broke out at his death,—six chiefs, between 1779 and 1789, ascended or claimed the throne, while Russia took advantage of the prevailing anarchy to encroach on the northern provinces, taking Georgia under her protection in 1783. The candidates for royalty were at length reduced to Lutf Ali Khan Zend and Aga-Mohammed Khan Kajar; the former, a brave but cruel prince, bore the title of king from 1789 to 1795, when he was taken and put to death by his rival, who thus became sole monarch, and the founder of the Kajar or reigning dynasty. He fixed his capital at Teheran. His first act was to attack the revolted Georgians, whom he overthrew in the field, and subjected their capital, Teflis, to ruthless pillage and massacre; but his severity provoked his own attendants to assassinate him, and he was succeeded by his nephew, the late Shah Futtah Ali (1797-1834). The early part of his long reign was marked by the rival intrigues of France and England at his court with reference to India. The principal subsequent events were his two disastrous wars with Russia, the first of which (1804-13) ended in the cession of most of the Caspian provinces by the peace of Goolistan; the second (1826-8), in the resignation of Eriwan and the country to the Araxes, by the treaty of Turkmanchai. He however reconquered Khorassan from the Afghans and Uzbeks, and broke the power of the chiefs of tribes by appointing his own numerous sons to nearly all the governments. At his death a struggle for the crown commenced among his descendants, but was speedily terminated, by the influence of England and Russia, in favour of the present Shah Mohammed, grandson of Futteh Ali by his son Abbas Mirza, who had been declared crown-prince, but died before his father. The reign of this young prince has not hitherto been auspicious; he appears to have thrown himself blindly into the arms of Russia, and the unsuccessful expedition which he undertook, in 1838, against the Afghan prince of Herat has not only exhausted his resources, but placed him in an attitude of hostility to the British power in India. Such is the present political position of Persia, of which the progress of time alone can develop the consequences; but the reduced power of the kingdom, and its situation between the two mighty and increasing Asiatic empires of England and Russia, of one of which it must virtually remain the vassal, apparently preclude the possibility of its ever again holding its former important rank in the scale of nations.

PERSIAN GULF, a large closed sea, connected with and consequently constituting a portion of the Indian Ocean. The entrance from that sea is by the strait of Ormuz, which in the narrowest point, between Ras Koli (or Cape Koli), in Persia, and Ras Mussendom, in Arabia, is about 38 miles wide. The gulf extends between 24° and 30° N. lat. and between 48° and 58° 30′ E. long. Its general form is that of a curve, the convex side of which is turned to the south-east. The direct distance between Ras Mussendom and the mouth of the Shat-el-Arab, which enters the most north-western extremity of the gulf, is about 550 miles; but measured along the curved line of the gulf, it is 600 miles. In width it varies between 40 and 200 miles, the greatest width occurring between 54° and 52° E. long. The average width exceeds 100 miles, and the area is about 70,000 square miles. The islands which are dispersed over this gulf are estimated at about 1400 square miles.

The navigation of this sea is dangerous and tedious, owing to the numerous shoals and reefs. These shoals and reefs are much more numerous on the southern or Arabian coast, which can hardly be approached in any part by large vessels without the greatest care, and it was accordingly for a long time the refuge of pirates, who by their boldness and activity increased the danger of the navigation in his sea. The most daring of these pirates were the Jawasimi, who had their principal station on the Arabian coast, at Ras-el-Khyma, about 60 miles from Ras Mussendom, and who were only compelled to keep the peace by two expeditions sent against them by the English from Bombay, in 1809 and in 1819. The navigation along the northern coast is comparatively free from danger, and the shoals are not very numerous. The largest are those which surround the western part of Kishm, and render the strait which separates that island from the continent so intricate; and the Berdistan Reefs, which render the coast of Persia, between 51° and 52° E. long., inaccessible to vessels above the size of a boat. In all other places, with some few exceptions, the soundings are regular, on a muddy or sandy bottom, and vessels, in case of necessity, find safety either in some of the small bays, or under the small islands, which are numerous along this coast. The places which are most resorted to by the shipping are the anchorage between the island of Ormuz and the town of Gombroon, the small bays of Mogoo and Bender Chetwar, the roadsteads of Busheer, and north of that town, the bay of Jenabe and Ras Dilem.

The prevailing wind during the whole year blows from the north-west. It is only during the months of November, December, and January that southerly winds may certainly be expected, especially in the Strait of Ormuz, where gales from the south-west and south-south-west are sometimes experienced. In other seasons of the year southern winds are of short duration, and they are constantly followed by north-western winds, the duration and force of which are always proportionate to the time that they have been interrupted by the southern winds. The Arabian navigators have observed that the northern winds blow regularly at certain seasons. They call them *shemaal*, and distinguish the great and the little shemaal. The great shemaal blows with considerable force for about forty days in June and July, but it it is not steady, being interrupted by calms and light winds. The little shemaal continues to blow for twenty days in March and April, with great force and without interruption. After this wind has blown four or five days, a strong current begins to run against it, which carries vessels daily twenty miles westward. This is produced probably by the accumulation of the water in the narrow, long, and curved strait by which the gulf is connected with the ocean. No other winds in this sea are steady except those which blow from the north-west, and sometimes those from the south-east. The rest are feeble, uncertain, and change frequently. The southerly winds blowing in winter are frequently accompanied with heavy rains, but the rains diminish towards the north, so that at Bassora, on the Shat-el-Arab, very little rain falls. These winds rarely last more than three or four days, and do not extend to the north-western part of the gulf.

Before the entrance of the gulf, between Cape Jask and Muscat, the currents are variable and uncertain, and usually subject to the wind (from the north-west); they set to the leeward. But sometimes they set against the north-western and northern winds, and thus cause what are called races. They run with more velocity along the shores than in the middle of the sea. It is stated that in the Strait of Ormuz itself, the current, from May to September, runs into the gulf, and in the remainder of the year out of it. Within the gulf, from Ras Mussendom to the mouth of the Shat-el-Arab, the current runs in the middle of the sea eastward; but it is often feeble, and sometimes it sets to the north. But a current is frequently met with along the coast of Persia which sets westward for several days together. Vessels therefore which sail to the west, keep close to the Persian shores, where, besides these currents, they are favoured by the land-breezes, which are not regular, but occur from time to time. The Arabian navigators are very expert in taking advantage of these circumstances.

The most remarkable of the numerous islands which are dispersed along the shores of the gulf are Ormuz [ORMUS], Kishm, Kaës, Busheab, Bahrein [BAHREIN], and Karej. Kishm is the largest island in the gulf, being miles long, and in the broadest part twenty miles wide. The surface is stated to exceed 500 square miles. On the southern side a ridge of hills extends from one extremity to the other, while the remaining space to the northward is occupied by arid plains and deep ravines. The greater part of the island is sterile, and in some places encrusted with a saline efflorescence, but there are also extensive tracts of fertile ground. The population exceeds 5000. K[illegible] the capital, at the eastern extremity of the island, is a place greatly resorted to by native vessels. It has a bazar, wel supplied with fruits and provisions, and some large and well built houses; the population is 2000. Laft, on the northern coast, on the channel which divides the island from the continent, was once the resort of pirates, but is now nearly abandoned. At Basidoh, or Bassadore, not far from the western extremity of the island, the East India Company had an establishment during the survey made by them of the gulf (from 1821 to 1828). Rice is cultivated, and date-trees are numerous. The island of Kaës, or Kenn, is small, the area hardly exceeding five square miles, but it is well cultivated, and produces wheat and tobacco. It has a small town, and a harbour for native vessels, which is frequently resorted to. The island of Busheab contains about forty square miles. It is uncultivated, but produces dates, and abounds in goats. It has a small town, and a harbour at the western end on the north side, where there is good anchorage for vessels of large burthen. The island of Karej, or Kharrack, contains about 26 square miles, and is surrounded by reefs, except at its north-eastern extremity. It is elevated, and visible at a considerable distance. The date-groves are extensive, and there is abundance of good water. Vessels sailing to Bassora obtain pilots here, who conduct them through the dangerous shoals at the mouth of the Shat-el-Arab.

Fish abound along the shores of the gulf; and fish and dates constitute the principal articles of food of the population. Nearly the whole population of the Arabian shores of this sea get their means of subsistence by the pearl-fishery. The most extensive pearl-fisheries are those on the several banks not far from the island of Bahrein; but pearl oysters are found, more or less, along the whole of the Arabian coast, and round almost all the islands of the gulf. Such as are fished in the sea near the island of Kharrack contain pearls which are said to be of a very superior description, but the water is too deep to make fishing for them either very profitable or easy near that island. At Bahrein alone the annual amount of the pearl fishery may be reckoned at from 1,000,000 to 1,200,000 German crowns (the coin current there), or from 200,000*l.* to 240,000*l.* The smaller fisheries, at Aboothatu, Sharga, Ras-el-Khyma, may produce half that sum, so that the whole produce may be between 300,000*l*, and 360,000*l.* About 1500 boats are employed in this fishery, and each contains ten persons, five divers, and five 'syebors,' or pullers-up.

The shores of the gulf are low, except near the Strait of Ormuz, where the mountains on both sides of Ras Mussendom rise to a considerable elevation, and come close up to the sea. This high coast extends within the gulf about [illegible] miles, and then the mountains on the Arabian shore recede to a great distance, leaving a wide plain which extends to the very mouth of the Shat-el-Arab. This plain is sandy, and produces only in a few places dates and a little grain. It is not known to what distance from the shores this plain extends. On all parts of the northern or Persian shore, mountains are visible from the sea. In some places they retire to a distance of 30 miles from the coast, and at others they approach it within three miles. These mountains are of moderate elevation, and in general do not much exceed 3000 feet above the sea, though a few summits rise higher, among which the highest is Mount Halaïlah or Ha[illegible], at the back of Cape Berdistan, which is supposed to attain a height of 5000 or 6000 feet. The low plain which lies between the shores of the gulf and the mountains is arid and sandy, and in many places swampy, but exceedingly hot. It produces very little grain, but dates in abundance, and is called by the natives Dushtistan or Gurmsir. Only one river of importance enters the Persian Gulf, namely, the Shat-el-Arab, which is formed by the confluence of the Tigris and Euphrates, and falls into the most northern recess of the sea by six or seven channels, of which however only the most western, called Cassisa Boni, or [illegible]ra river, is navigable for vessels of considerable burthen. The plain which here borders on the Persian Gulf extends eastward on the banks of the rivers to the mountain-ranges which surround the Black Sea on the south. The largest river next to the Shat-el-Arab is the Tab, which falls into the gulf not far from the most eastern mouth of that river; its course is probably less than 100 miles in length, and it is only navigable for boats of 20 tons burthen to the town of [illegible]an, 16 miles from the mouth.

It is remarkable that the shores of this gulf, in their whole extent, are inhabited by one nation, the Arabs. The Arabs are in possession of the whole country to the south of the gulf, which is also called Arabia; but on the northern shore they occupy only the Dushtistan, or low plain; the mountains at the back of it, as well as the table-land of Iran, which lies behind these mountains, being in possession of the Persians. As the low plain is inhabited exclusively by Arabians, one of the sovereigns of Arabia, the iman of Muscat, has succeeded in establishing his authority over nearly the whole extent of it, at least as far west as Ras Berdistan, and the king of Persia has left him in possession of it, but the iman pays him an annual rent.

The earliest navigation of this gulf which is on record is the voyage of NEARCHUS.

Journ.*, vol. iii.; Whitelock's 'Descriptive Sketch of the Islands and Coast situated at the Entrance of the Persian Gulf,' in the *Lond. Geogr. Journal*, vol. viii.)

PE'RSICA. [PEACH.]

PERSICA'RIA is the garden name of a species of Polygonum (P. orientale), a handsome annual, growing about six feet high, and strikingly ornamented with drooping clusters of pink flowers. It is very different from the Polygonum Persicaria, a wild acrid plant, growing in ditches, and of no great beauty.

PERSI'COLA, Schumacher's name for one of the *Marginellinæ*. [VOLUTIDÆ.]

PERSIMON is the fruit of the *Diospyrus Virginiana*, a tree inhabiting the United States of America, especially the southern, where it becomes 60 feet or more in height, with a trunk 18 or 20 inches in diameter. It has ovate-oblong taper-pointed shining leaves, pale yellow flowers, and a succulent reddish fruit about as large as a small plum, and containing a few oval stones. After having been exposed to frost, it becomes sweet, but, like our medlars, is astringent and uneatable at an earlier period. In the American nurseries is a sweet Persimon, said to be superior in quality to the wild kind. It is eaten both by man and wild and domestic animals; it is also pounded, dried, and made into cakes, or it is bruised and fermented, and yields by distillation an ardent spirit. Its timber too is strong, elastic, and of considerable value. The bark, which is very bitter, is said to be tonic. In Great Britain it has long been cultivated, and there are fine specimens at Kew, Lynn, and elsewhere. Its fruit is however seldom produced. The Persimon is very nearly the same as the Lote or Date Plum of Switzerland, which is the *Diospyrus Lotus.*

PE'RSIUS, AULUS FLACCUS, a Roman satirist, was born at Volaterræ, a town of Etruria, about the 20th year of the reign of Tiberius, A.D. 34. He was of equestrian rank. At the early age of six years he lost his father. His mother, who was afterwards married to another Roman knight, appears to have bestowed extraordinary care upon Persius; and he appears to have shown towards her the strongest filial affection.

Persius was trained at Volaterræ till his twelfth year, and he then proceeded to Rome, where he studied grammar under Rhemnius Palæmon, and rhetoric under Virginius Flaccus. At the age of sixteen he became a pupil of Annæus Cornutus, a Stoic philosopher, who had come from Leptis in Africa to settle at Rome. Lucan, the poet, was his fellow-disciple in the school of Cornutus. Persius and Cornutus were bound to each other by feelings more like those of father and son than such as usually subsist between preceptor and scholar. This friendship continued without interruption till the death of Persius, which took place in his 28th or 30th year. He bequeathed his books and a large sum of money to Cornutus, who however declined to receive the latter, and gave it up to the sisters of Persius.

The materials for a life of Persius are scanty; but they are sufficient to show him in a very favourable light. Amidst prevailing corruption, he maintained a high moral character. He consistently applied his principles as a Stoic to the purposes of self-discipline. His acquaintance with men and things was the result of private study more than of actual converse with the world, so that, as his writings testify, he viewed human life as he thought it should be, rather than as it really was. Different opinions are formed of Persius as a satirical poet. Quintilian and Martial, with some of the early Christian writers, bear a high testimony to his merits, as do likewise several modern critics. Others consider him not worth reading. Gifford, who has studied him thoroughly, says, among many eulogies of him, 'His life may be contemplated with unabated pleasure; the virtue he recommends, he practised in the fullest extent; and at an age when few have acquired a determinate character, he left behind him an established reputation for genius, learning, and worth.'

The works of Persius consist of six Satires with a prologue, which seems however not a very suitable introduction either to the first satire or to the six satires taken as one work. The metre of this prologue, which comprises 14 lines, is of the kind called choliambic (lame iambic), or scazon (halting), of which kind are seven of the poems of Catullus. The Satires contain altogether only 650 hexameters; and in some manuscripts they are given as one continuous work. Whether Persius wrote more than we now possess, as the author of his life attributed to Suetonius affirms, we know not; but since Quintilian and Martial speak of his claims to distinction, though he left 'only one book,' we should conclude that no other production of his was known in their time.

Much has been said respecting the obscurity of Persius, and it has even been stated that he meant not to be easily understood. It is not very likely that a man ever wrote seriously with the intention of being obscure. It is granted that Persius is obscure; but he was, no doubt, plain enough to his contemporaries, who were acquainted with the principles of the Stoic philosophy, and with the persons and things generally referred to. Modern readers without such a key will of course find difficulties in Persius. Commentators have however thrown much light upon this author, and among them Isaac Casaubon may be mentioned first; but his comment is copious enough to frighten most readers of the present day. The comment of Koenig is briefer. 'But that of Bond may be recommended as the best, particularly because it comes directly to the point, and brings forward short passages from other writers in such a way as greatly to illustrate the phraseology of Persius.' The English reader may derive a correct idea of Persius from the translation and notes of Gifford.

The best editions of Persius are those of Isaac Casaubon, revised by his son Meric, London, 1647; Bond, Norib., 1631; Koenig, Gött., 1803, and with Rupert's *Juvenal*, Glasg., 1825. English translations have been made by Holyday, Dryden, Brewster, Sir Wm. Drummond, and Gifford.

(*Life of Persius* attributed to Suetonius; Fabricius's *Bibliotheca Latina*; Ruperti; Koenig; Gifford.)

PERSONAL ACTIONS. [ACTIONS.]

PERSONALTY AND PERSONAL PROPERTY. [CHATTELS.]

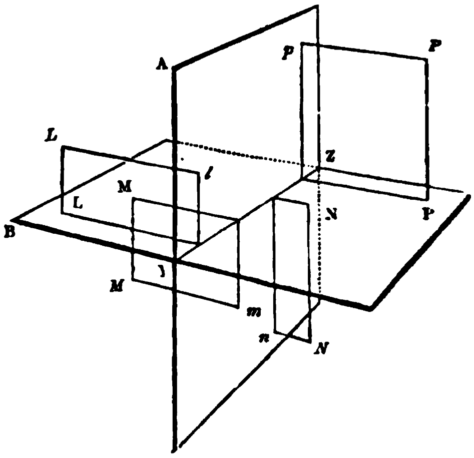
PERSPECTIVE, a term popularly given to an application of geometrical principles, by means of which a *pictorial* outline of a certain class of objects may be delineated on a plane surface. It is consequently connected with the arts of design. [DRAWING.] Perspective constitutes however only a specific case of a more general application of the principles alluded to, which enable us to make constructions relating to geometrical *solids*, bearing the same relation to geometry of three dimensions that practical bears to theoretical plane geometry.

The analyst, in his investigations of symbolical expressions for the relations of geometrical magnitudes, refers these, according to the species of magnitudes under consideration, either to co-ordinate lines on a plane, or to co-ordinate planes, assumed at pleasure in space. [CO-ORDINATES.] The draughtsman, or practical geometrician, makes his constructions on the lines and figures themselves, when they lie wholly in one plane; and when he has to make constructions on geometrical solids, he is compelled to refer the various points, lines, and figures connected with or constituting those solids to one or more planes, to effect his object; and from constructions on these planes he can determine the unknown quantities of the original solids by means of their *projections*, as they are termed, knowing the conditions under which these projections were obtained.

1. The series of points of any geometrical solid are most simply supposed to be referred to a plane by parallel right lines, passing through them perpendicular to the plane; the intersections of these lines with the plane are termed the *projections* of the original points on that plane.

2. Let us conventionally designate the original points by Italic capital letters, and their projections by Roman letters: thus *P* means a point in space, *p* its projection on a plane.

3. The points *l*, *m*, *n*, on a plane AYZ, are therefore understood as referring to points in space, situated in right lines passing through *l*, *m*, *n* respectively, perpendicular to that plane; but these projections alone do not define the relations between the original points; for *l*, *m*, *n* are each the projections of an infinite number of original points, all in short through which each *projecting line* may pass. To define the specific points *L*, *M*, *N*, we must consequently not only have *l*, *m*, *n*, but the lengths respectively of the projecting lines *Ll*, *Mm*, *Nn*, or the distances at which *L*, *M*, *N* are respectively situated from their projections.



4. This second series of essential data is furnished by projections L, M, N of the original points on a second co-ordinate plane BYZ, perpendicular to the first, and therefore parallel to the former projecting lines, by which *l*, *m*, *n* were determined; while, conversely, the first plane must be parallel to the projecting lines by which L, M, N are determined. For if a third plane be conceived to pass through the two projecting lines *L*L, *Ll*, of any point *L*, and therefore necessarily perpendicular to the two co-ordinate planes, the intersections of this third plane with the two latter will, together with the two projecting lines themselves, form a rectangle; consequently the distance of any projection L from the common intersection YZ of the co-ordinate planes is equal to the length of the *projecting line Ll*, which is parallel to it; while, conversely, the distance of the other projection *l* of the same point *L* from the same common intersection is equal to the length of the *projecting line* L*L*.

5. Let us designate the third plane just described as the *projecting plane* of an original point. It follows as a corollary from this definition of the plane, that the *projecting planes* of a series of points L, M, N are parallel to each other, and perpendicular to both co-ordinate planes, as well therefore as to the common intersection YZ of those co-ordinate planes.

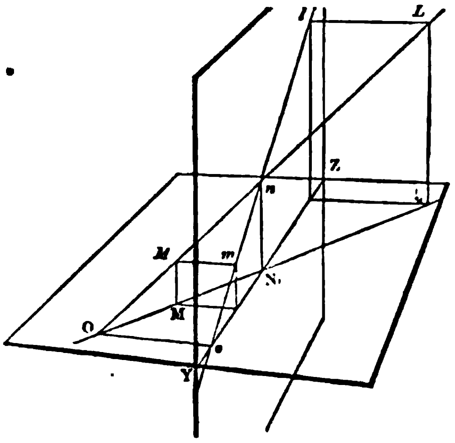
6. Let YZ always designate the common intersection of the two co-ordinate planes; let the projections L, M, N be termed the *plans*, and the projections *l*, *m*, *n*, the *elevations* of the original points *L*, *M*, *N*. It follows that if an original point lie in either co-ordinate plane, its projecting line will coincide with that plane, and its projection on the other will be a point in YZ.

7. Let us next consider a right line *LM*, supposed to join or pass through two points in space *L*, *M*. Then the right line LM, joining or passing through the *plans* of *L* and *M*, is called the *plan* of *LM*, and *lm* is the *elevation* of the same original line.

8. It is obvious, from the preceding definitions, that the *plan* and *elevation* of any original right line *LM* in space are the intersections with the co-ordinate planes respectively of two planes passing through the original line perpendicular to the co-ordinate planes.

9. We will distinguish the projecting plane of an original line *LM*, by which the *plan* of that line may be conceived as produced, as the *plan-projecting plane* of *LM*; and the projecting plane by which *lm* is produced, as the *elevation-projecting plane*. But the reader must not confound the *projecting plane* of an original point, which is necessarily perpendicular to both co-ordinate planes, with the *projecting*

plane of an original line; which, though necessarily perpendicular to one co-ordinate plane, may be parallel, perpendicular, or oblique to the other, according as the original line is parallel, perpendicular, or oblique to that other co-ordinate plane. Nevertheless the projecting plane of an original line will always intersect that co-ordinate plane, to which it is not necessarily perpendicular, in a line which is perpendicular to YZ.



10. Besides the plan and elevation, there are two other elements regarding an original line which it is necessary to consider; these are the points in which that line itself intersects the two co-ordinate planes. The principles of projection furnish us with the following theorems relating to these points, and to the plan and elevation of the line.

11. If the original line be parallel to both co-ordinate planes, it can intersect neither, and both its plan and elevation are parallel to YZ. It is clear, on this supposition, that the original line is itself also parallel to YZ.

12. If the original line be perpendicular to one, and therefore parallel to the other co-ordinate plane, the projection on that other plane will be parallel to the original, and perpendicular to YZ, while the projection on the first will be a point, that in which the original line itself intersects that co-ordinate plane.

13. If the original line be oblique to one, and yet parallel to the other co-ordinate plane, its projection on that to which the line is *not* parallel will be parallel to YZ; while its projection on the co-ordinate plane, to which the original is parallel, will cut XZ in the projection of the point in which the original intersects the former co-ordinate plane.

14. If the original line be oblique to both co-ordinate planes, neither its plan nor elevation can be parallel to YZ; the plan of the line will cut YZ in the projection of the point of intersection of the original with the co-ordinate plane in which its elevation lies; while that elevation will cut YZ in the projection of the intersection of the original with the plane in which the plan lies.

15. It also follows that the projecting line of the point in which an original line intersects either co-ordinate plane coincides with the intersection of the projecting plane of that line.

16. If an original line, oblique to both co-ordinate planes, lie in a plane perpendicular to them both, its plan and elevation will both be perpendicular to YZ, since its two projecting planes will coincide with that in which the line lies. In this case the plan and elevation could not furnish sufficient data for determining the original lines, since they would be common to every line, in the perpendicular plane, which was not parallel to either plane of projection; if however we have, in addition to the indefinite plan and elevation of the line, those of two points in it, or the two points in which the original line cuts the two co-ordinate planes, then the original line is determined.

17. Let us next consider in what manner an original plane may be conceived to be referred to two co-ordinate planes. It is clear that as only one plane can be drawn through a straight line and a point, or, which is the same thing, through the two legs of a plane angle, the plans and elevations of any two lines through which the plane passes will determine it. But the intersections of the original plane with the two co-ordinate planes furnish a datum regarding it of more direct application.

18. The intersections of an original plane with the co-ordinate planes are termed its *traces*.

19. The traces of a plane on either co-ordinate plane will obviously pass through the points in which two or more lines lying in the original plane intersect that co-ordinate plane.

20. If an original plane be parallel to one co-ordinate plane, its trace on the other will be parallel to Y Z.

21. If an original plane be perpendicular to either co-ordinate plane, its trace on the other will be perpendicular to YZ, at the point in which the trace on the first plane meets that line; and the plane oblique angle formed by the trace and YZ will be the measure of the dihedral angle formed by the original with the other co-ordinate planes. If an original plane be perpendicular to a co-ordinate plane, its trace on that plane will be the common projection of all lines in the original plane, and will pass through the projection of all points in that original plane.

22. If the original plane be parallel to YZ, its traces on the co-ordinate planes will both be parallel to YZ, and therefore to each other; but in every other case, if the original be oblique to both, or meet both co-ordinate planes, its traces on them must intersect in a point of YZ. And if the plane be perpendicular to both co-ordinate planes, both its traces will be perpendicular to YZ.

23. If two original lines are parallel, the plans of those lines will be parallel, as will also be their elevations: but the plans or the elevations only of two lines may be parallel, although the lines themselves are not so, the parallelism of either the plans or elevations simply arising from the accidental parallelism of the plan or elevation projecting planes of the original lines.

24. An analogous theorem applies to two original planes: if these be parallel, their traces on both co ordinate planes will be parallel; but if their traces are parallel on one plane only, it simply indicates that the original planes intersect each other in a line parallel to that co-ordinate plane.

25. The plans of two lines may cut one another, as may also the two elevations, and yet the originals may not lie in one plane, and therefore cannot meet each other. If two original lines really intersect, the points in which the plans and elevations cut each other must lie in the projecting plane of the point in which the originals meet.

26. The projections of equal parallel lines will be equal parallels, in the ratio to the originals of the cosine of the angle in which those originals are inclined to the plane of projection, to radius. If two lines forming an angle be parallel to two others, whether lying in the same or different planes, the projections of each two lines will form equal angles.

27. The plane angles, which are the projections of equal angles, will be equal, provided the original angles are similarly placed with respect to the traces of the planes in which those originals lie; or else when the original angles lie in a plane parallel to either co-ordinate plane, and then the projected angles must be equal to the originals.

28. Hence, since the projection of every parallelogram is a parallelogram (23), the angles of the projection corresponding to the adjacent angles of the original figure will also be complementary to each other.

29. If an original plane and line be mutually perpendicular, the projection of the line will be perpendicular to the trace of the plane on each co-ordinate plane. For since the projecting plane of the line must, on this supposition, be perpendicular both to the original and to the co-ordinate plane, and consequently so to their common intersection, which common intersection is the trace of the plane, this projecting plane will cut the co-ordinate plane in a line, namely the projection of the original, perpendicular to the trace of the plane.

30. If a line in an original plane be parallel to a co-ordinate plane, the projection of that line will be parallel to the trace of the plane; and conversely, if the projection of a line situated in a plane be parallel to the trace of that plane, the original line is parallel to the co-ordinate plane in which that trace lies.

31. These theorems on projections would be useless to the practical geometrician so long as the co-ordinate planes are supposed to retain their relative situation in space: to enable him to make the requisite constructions on the projections, and to determine the unknown magnitudes entering into the original solids by means of the projections of the known ones, he supposes the one co-ordinate plane turned

round on the common intersection YZ till the two planes coincide in one and the same plane: by this supposition the relations to YZ of the lines, points, and traces, on the plane which is supposed to be turned round, remain unaltered; while the principles on which the projections are made allow of the correct interpretation of the new relations which the projections of original points and lines on one plane assume with regard to the projections of the same points and lines on the other plane, when these two co-ordinate planes are supposed to coincide in one.

32. The same method of bringing two planes into one may be applied, or rather conceived to be applied, to the *projecting plane* of any original point or line, this projecting plane being supposed turned round on the projection of the line till the plane coincide with the co-ordinate plane, that is to say, a construction can be made with the projection of a line founded on this supposition, by which a line may be found representing the original line as brought into the co-ordinate plane; and by an analogous construction, an original plane may be constructed as if turned round on its trace till it coincide with the co-ordinate plane.

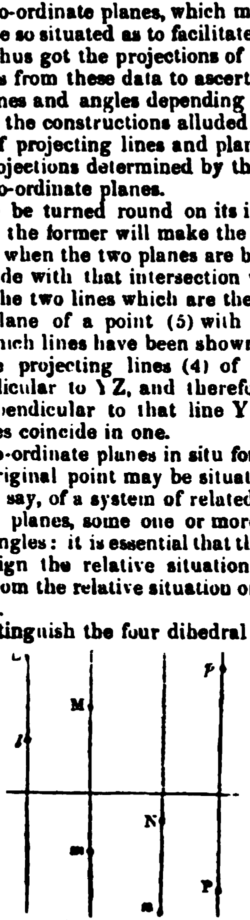
33. This principle may be carried still farther: thus a construction can be made, founded on the supposition that an original plane has been turned round on its intersection with another such plane till they coincide, and this compounded plane, if we may use such an expression, has been again turned round on its trace till it has been brought into the common plane of projection.

34. It must hence be understood that the practical application of the theory of projections is entirely synthetical, that is, the draughtsman, first drawing a line to represent YZ, proceeds from this simple assumption to draw the projections of certain points and lines of a solid, on which he proposes to operate, from their known, assumed, or given relations to each other, and from their conventional relations to the supposed co-ordinate planes, which may in every case be conceived to be so situated as to facilitate these constructions. Having thus got the projections of known or given lines, he proceeds from these data to ascertain the absolute magnitudes of lines and angles depending on these given ones, by making the constructions alluded to, founded on the supposition of projecting lines and planes being turned round on the projections determined by them, till they coincide with the co-ordinate planes.

35. If a plane be turned round on its intersection with another, a line in the former will make the same angle with that intersection, when the two planes are brought into one, that the line made with that intersection when the planes were in situ. The two lines which are the intersections of the projecting plane of a point (5) with the co-ordinate planes in situ, which lines have been shown to be equal respectively to the projecting lines (4) of that point, will be both perpendicular to YZ, and therefore will coincide in one line perpendicular to that line YZ, when the two co-ordinate planes coincide in one.

36. The two co-ordinate planes in situ form four dihedral angles, and an original point may be situated in any one of these: that is to say, of a system of related original poin s referred to those planes, some one or more may be in different dihedral angles: it is essential that the learner should know how to assign the relative situation of the original points in space from the relative situation of their plans and elevations to YZ.

37. Let us distinguish the four dihedral angles thus:—

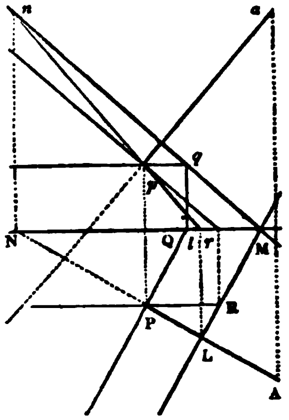


1. $+x+y$; the point P,p[*] is in the dihedral angle No. 1.
2. $-x+y$; „ L,l „ „ No. 2.
3. $-x-y$; „ M,m „ „ No. 3.
4. $+x-y$; „ N,n „ „ No. 4.

38. Our limits will only admit of two or three examples of elementary constructions to illustrate the subject of projections, referring to the theorem on which each step of the construction is founded.

Given a point P,p *in a given line* AP, ap, *to draw a plane through* P,p *perpendicular to the given line.*[*]

39. Draw a line PQ through P, perpendicular to the plan of the line, for that of a line parallel to the co-ordinate



plane, and lying in the plane sought; then (20) pq, parallel to YZ, will be the elevation of this parallel. The line PQ, pq meets the co-ordinate plane in Q,q (13), q therefore will be a point in one trace of the plane sought: and since this trace must be perpendicular to the elevation of the line, M n drawn through q perpendicular to ap will be that trace. The same construction, applied, mutatis mutandis, to the other projection of the point, will furnish a point in the horizontal trace of the plane sought, which trace must be drawn through R perpendicular to AP. The two traces thus found will intersect each other in a point of YZ (22).

Given a plane LM, Mn, *and a point* A,a: *to draw a line through the point perpendicular to the plane, and to determine the point in which this line cuts the given plane.*

40. Through A,a draw lines perpendicular to the given traces LMn for the indefinite projections of the perpendicular sought (29): from the point N, in which AN cuts YZ, draw N n perpendicular to YZ for the intersection with the other co-ordinate plane of the plan-projecting plane of the perpendicular (9); and from L, in which AP cuts ML, draw L l perpendicular to YZ: the point l is the elevation of the point in which the plan-projecting plane of the perpendicular cuts the trace LM, M l; and n is that in which the same plane cuts the trace M n. Consequently n l is the elevation of the intersection of the same plan-projecting plane with the original plane. Now it is obvious that the point sought must lie in this intersection; consequently the point p, in which ap cuts nl, must be the elevation of the point in which the perpendicular intersects the given plane.

41. The plan P of the point may be obtained by drawing Pp perpendicular to YZ (35), to cut AN, the indefinite plan of the line; or by applying the foregoing construction, mutatis mutandis, to the other projections.

To draw a line through a given point P,p, *to make any proposed angle with a given line* AB, ab.

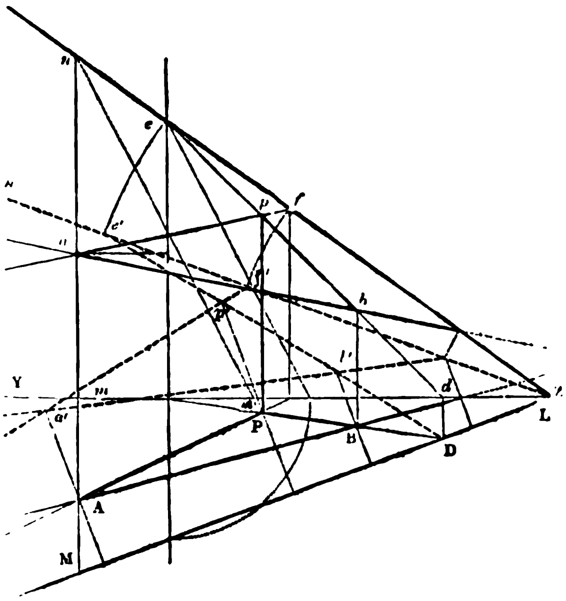
42. If the proposed line is to be *parallel* to the given one, lines drawn through the projections of the given point, parallel respectively to those of the given line, will be the projections of the line sought (23); but if the lines are not to be parallel, join P,p with any two points A,a, B,b, taken at pleasure in the given line. ABP will therefore be the plan, and abp the elevation of the triangle thus formed. Find the traces, ML, Ln, of the plane of this triangle, by

---

[*] 'The point P, p,' 'the line AB, ab,' 'the plane LM, Mn,' signify the point, line, or plane, the plans, elevations, or traces of which are A,a; A B, ab; LM, Mn, respectively.

[*] This is the form of enunciation of a prob. in solid geometry, and is to be thus interpreted: Given the projections P and p, on two co-ordinate planes supposed to be brought into one, of a point P situated in an original line of which the corresponding projections, AP ap, are given; to draw the lines (traces) which will represent the intersections of a plane with those co-ordinate planes, this plane being supposed to pass through P, and to be perpendicular to *AP*.

finding the points in which any two of its sides intersect the co-ordinate planes (19), since these points must lie in the traces required.*



43. Draw M*n* perpendicular to YZ, to cut the traces anywhere at pleasure in points M, *n*; the line M*m*, *n* is consequently the traces of a plane assumed at pleasure as perpendicular to both co-ordinate planes (22), and cutting the given plane ML*n* in a line, the projections of which, of course, coincide with the traces of the plane. The length of this line, or the real distance between the points M*n* when in situ, is obtained by making mm' in YZ equal to *m*M; then the hypothenuse $m'n$ is the intersection of the given plane with the assumed plane, brought into the plane of projection by the rotation on *mn* of this assumed plane.

44. From M and L, as centres, with $m'n$, L*n* for radii respectively, describe arcs cutting in n'. Join Mn', Ln'; the triangle MLn' consequently (32) represents that portion of the given plane ML*n* intercepted between the co-ordinate planes and the line M*m*, *mn*, brought into the co-ordinate plane by being turned round on the trace ML, and by this rotation, bringing the original of the triangle, PAB, *pab*, along with it. To draw this triangle as thus brought into the co-ordinate planes, produce PB, *pb* to cut the two traces in D and *e* respectively, make Le' equal to L*e*, join De'. In the same manner the lines $a'p'$, $a'b'$ are obtained, constituting the original triangle as brought into the co-ordinate plane in the manner described.

45. The points A,*a*, B,*b*, P,*p*, lying in the original plane, will describe arcs of circles during the rotation of that plane on its trace: the planes of these circles must obviously be perpendicular to the original plane and to the co-ordinate plane, and consequently cut the co-ordinate plane in lines or traces perpendicular to ML, that of the original plane. Hence if lines be drawn through A, B, and P, perpendicular to ML, they will pass through a', b', and p', since the traces of these planes will be the projections of all lines lying in them, and therefore of the circular arcs alluded to (21) in which the points a', b', and p' lie. By this means the points a', b', and p' may be found, or verified if previously obtained on any other principle.

46. Draw $p'a'$ to make the proposed angle with $a'b'$†; then the plan A, and elevation of the point a', in which the proposed line meets the given one in the given angle, may be determined from a' by the converse proceeding to that by which a', b', and p' were obtained. And lastly, PA, *pa* will be the projections of the line as required.

47. The foregoing construction might have been made with the trace L*n* instead of LM; but the triangle, when brought into the co-ordinate plane on the supposition of the rotation of the plane of that triangle on L*n*, would not coincide with $a'b'p'$.

48. If a line be conceived to move always perpendicular to a co-ordinate plane, and pass through an original curve, its intersection with the plane will be the projection of the curve; this projection being the section of the cylindroidal surface formed by the generating line. If the curve be any other than a circle or an ellipse, its projection can only be practically described by finding the projections of a sufficient number of points of the original, from some known property of the curve, or from the mode of its generation; and the required projection must be drawn by hand through the points thus determined. It is obvious that the projection of any plane curve which is parallel to the co-ordinate plane must be equal and similar to the original. But if the original curve be a circle, or an ellipse, the projecting line during its motion will generate a right or oblique cylindrical surface, the section of which by the co-ordinate plane must be either a circle or an ellipse.

49. Whatever may be the oblique position of an original circle with respect to the co-ordinate plane, there must be one diameter which is parallel to that plane; now the projection of this diameter being equal to the original, must be greater than those of all the other diameters of the original circle, which are all necessarily oblique to the plane: and since the projection of every diameter must be a diameter of the projected curve, the projection of this parallel one must be the major axis of the ellipse. This diameter of the original circle parallel to the co-ordinate plane is that which is parallel to the trace of the plane. The conjugate axis of the ellipse will be the projection of that diameter of the original circle which is perpendicular to the former, or to the trace of the plane.

50. The projection of a sphere on a co-ordinate plane must be a circle of the same radius as the sphere, this circle being the projection of that great circle of the solid which is parallel to the co-ordinate plane.

51. In the applications of practical geometry to the arts, the object is either to delineate the forms to which materials are to be reduced, or to guide workmen in making and putting together machinery; or, in the construction of edifices of every description.

52. Owing to the symmetry of the machines or edifices, the forms most commonly required to be delineated are reducible to series of rectangular geometrical solids, the planes of which are either parallel or perpendicular to the horizon. The plans, elevations, sections, profiles, &c., furnished to the workman by the draughtsman, are the projections on rectangular co-ordinate planes, assumed to be parallel to the planes of the machines or edifices, made to a reduced scale; the plan being such a projection, made on a horizontal plane, and the elevation on a vertical plane. When the building or engine is supposed to be laid open, by being cut by a plane, so as to show its interior, the projection made on this supposition is termed a section, or profile.

53. It is obvious, from these assumptions, that the various plane rectilinear, or mixed, figures which are produced by the intersections or boundaries of the various surfaces of the original objects, are represented on the draughtsman's plans, &c. by figures similar to the original forms; and that those plane surfaces of the original object which are vertical to the horizon appear only as right lines on a plan, bounding the figures which are the representatives of original planes parallel to the horizon; and, conversely, these last-mentioned surfaces are represented by lines in the elevations, while the vertical plane figures of the original are projected into similar plane figures on these elevations or profiles.

54. Hence two, at least, and commonly three, such projections, on rectangular co-ordinate planes, are requisite to convey an idea of the forms of an original object; but since these forms of the original are represented of their true dimensions and proportions, such projections are sufficient, and indispensable, as guides to the mechanics who are to construct or put together the edifice or machine.

55. The principles of projection enable us, as far as regards the rectangular parallelopiped, the solid of most frequent occurrence, to combine the two purposes for which such projections are employed; that is, to convey, by one image or figure, an accurate idea of the relative position of the parallel and vertical planes of an original object, reducible to this form, and at the same time to preserve one constant

---

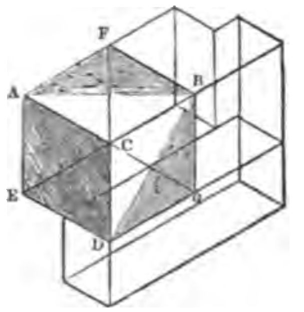
* The sides of the triangle may meet the co-ordinate planes in different dihedral angles; the projections of two of these points, through which the same trace must pass, may therefore lie on contrary sides of YZ. The traces of all planes should be drawn indefinitely extended on each side of this line YZ, or are to be conceived as so extended when circumstances do not admit of their being shown so.

† In the figure, $p'a'$ is shown as the same line as the side of the assumed triangle, to avoid confusion; but this, obviously, need not be the case.

and correct proportion between the magnitudes of the original and of its representative.*

56. It has been shown (26, 27) that the projections of definite right lines, inclined in equal angles to the co-ordinate plane, will be in a constant proportion to the originals; if therefore the three plane right angles forming a solid angle of a rectangular parallelopiped be inclined in equal dihedral angles to the co-ordinate plane, all lines parallel to the three edges of that solid angle will be projected into lines bearing one constant ratio to the originals, and forming with each other equal angles, which are the projections of the right ones formed by the original lines.

57. Thus, for example, if the co-ordinate plane be assumed perpendicular to the diagonal of a cube, the projections of the three edges meeting in either end of that diagonal will form angles of 120° with each other, and the three projections of the edges at one extremity will, respectively, bisect the equal angles formed by those of the edges at the other extremity; while the lines joining the ends of these six equal radii, which lines must obviously form a regular hexagon, will be the projections of the remaining edges of the solid. Each face of the cube is projected into an equilateral rhombus, as ACBF, BCDG, ACDE, BFCG, &c., the sides of which form angles respectively of 120° and of 60° each. If the side of the cube be unity, the equal projections of those sides will be ·8165, which is equal to the cosine of the angle at which the originals are inclined to the co-ordinate plane. The original diagonals of the three faces, AB, BD, DA, are obviously, from the symmetry and position of the solid, parallel to the co-ordinate plane; their projections are therefore equal to those originals, or are each equal to $\sqrt{2}=1\cdot4142\ldots$ If an original solid be made up of rectangular parallelopipeds, having their faces mutually parallel, and the co-ordinate, or plane of projection, be assumed as equally inclined to the three faces forming any of the solid angles, the projections of all its edges, and of all lines parallel to them, would be in the constant ratio to the originals of ·8164 : 1; the dimensions, consequently, of those originals, as measured in the directions of lines which would be isometrically projected, may be set off from any scale along the isometric projections of any lines parallel to the edges of the original solids, and a figure or image of the original constructed which would show the three principal series of planes of which that original was composed.



58. The projections of all circles equally inclined to the co-ordinate plane will be similar ellipses; the axes of these ellipses, when representing circles lying in planes parallel to the faces of a cube equally inclined to the co-ordinate plane, will be to each other in the ratio of the diagonals of the rhombus representing the inscribed or circumscribing square isometrically projected. The following simple method of constructing a scale for determining the lengths of the axes of the isometric projection of a circle will be of service to the practical draughtsman. Construct a right angled triangle the base and perpendicular of which are in the ratio of the side to the diagonal of a square, or as 1 : 1·4142. Set off the length of the isometric projection of the circumscribing square of any original circle along the side of this triangle, from the acute angle, and draw a line parallel to the other side from the point thus marked off; this parallel, and the segment of the hypothenuse cut off by it, will be the minor and major axes of the ellipse. Since the major axis of the elliptic projection of a circle is always equal to the diameter of that circle (49), the major axis of the isometrical projection of a circle is equal to the side of the circumscribing square. Hence the axes of the ellipse and the side of the circumscribing square, when isometrically projected, are as $\sqrt{3}$: $\sqrt{1}$; $\sqrt{2}$.

59. The projecting lines and planes are assumed perpendicular to the rectangular co-ordinate planes, simply to facilitate the construction; but it is obvious that lines and figures may be projected on a plane by parallel projecting lines, making any angle with the plane of projection; such projections are termed *oblique*, but as they are but seldom employed, we shall only here give two general theorems relating to them; since we shall have occasion to recur to this subject in a subsequent part of this article. The oblique projection of a straight line, figure, or curve, lying wholly in a plane parallel to the co-ordinate plane, will be similar and equal to the original; and the oblique projections of parallel right lines will be parallels.

60. The oblique projection of a sphere must be an ellipse, for the parallel projecting lines which are tangential to the spherical surface must always form a right cylinder, the oblique section of which must be an ellipse. The major axis of this ellipse will be the intersection with the co-ordinate plane of one perpendicular to it, and passing through the oblique projecting line of the centre of the sphere. This major axis will consequently pass through the perpendicular, or ordinary projection of the centre of the sphere. The conjugate axis must clearly be equal to the diameter of the sphere.

61. We must now proceed to show how, by a modification of the principles of projection, an image of an object, or a pictorial outline of it, may be obtained, which will convey an idea of the original, just as the outline portrait of an absent person conveys to the spectator an idea of his appearance. It is however only to buildings, engines, machines, &c., consisting of strictly geometrical forms, that this modified projection can be applied; since the constructions by which these projections are obtained are as strictly geometrical as those by which we obtain the projections of such objects on co-ordinate planes.

62. Each point on the surface of an object is seen in the direction of a straight line,* supposed to be drawn from that point to the eye, and representing the reflected ray of light by which that point is rendered visible. The rays from every point of that surface will obviously form a geometrical solid pyramid, the surface of which will be composed of those rays which, touching the object, might be supposed prolonged in the same straight direction beyond it, without penetrating its surface. But when considering the subject of *outline* alone, we need only regard such of the internal rays of the pyramid as proceed from lines on the surface of the object, produced by the intersections of portions of that surface not continuous: and from our limitation of the class of objects, such lines must be either straight, or else geometrical curves; resulting from the mutual intersections of planes and curved surfaces with each other.

63. The general pyramid of rays will therefore be made up of a series of others, having one common vertex, and for their several bases the perimeter of a portion of continuous surface.

64. If we imagine these pyramids of rays cut by a plane, the common section will obviously be an outline of the object as it would present itself to an eye placed at the vertex, each line and point of the section coinciding with the corresponding line and point of the original.

65. As long as the object and the spectator's eye retain the same relative position, it is immaterial in what direction or at what distance the plane cuts the pyramids of rays, for the lines and points produced at each position of the plane must necessarily coincide with the originals when viewed from the vertex; although the outlines on the plane would vary for each of its positions. But each of these different outlines would suggest to the mind the same original combination of forms, provided it be viewed from the true vertex, and cannot be a correct representation or image of the object, if viewed from any other point.†

66. When we revert to the connection between this and

---

* This specific application of projection was termed isometric by the late Professor Farish, who pointed out its practical utility, and the facility of its application to the delineation of engines, &c.; as a distinctive one, this term is unexceptionable.

* We need hardly allude to the modification of this assertion rendered necessary by the effects of atmospheric refraction. It is evident that the forms of objects which can be seen by the eye at one time are in no way influenced by these effects, which may therefore be neglected in treating this subject.

† There is a common toy which well illustrates this subject; we allude to a distorted image of a building, which, when viewed from a certain fixed point, presents a natural appearance. This distorted image is a correct section of a pyramid of rays supposed to proceed from the building to the point in question, and therefore when viewed from that true vertex, conveys the same impression that the building itself would do.

ject and drawing, in the common acceptation of the word, we shall point out the precautions that must be taken by the draughtsman, when applying the principles of projection to the pictorial delineation of objects, to prevent his drawing from appearing distorted when viewed indifferently from other than the correct point, which it must inevitably be on most occasions. But at present, dismissing all considerations of light, vision, and art, we shall proceed to treat this branch of the subject of projections, termed perspective, in a purely geometrical manner.

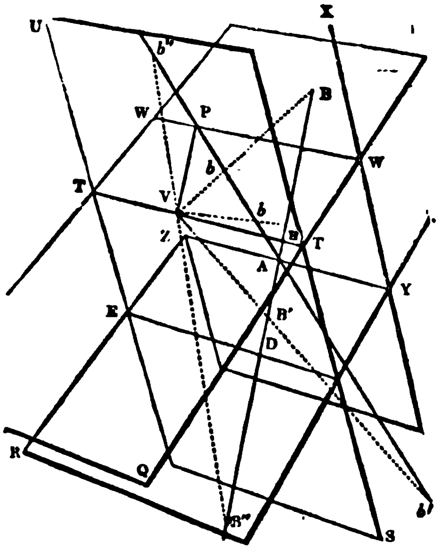
67. Instead of the simple elements alone, which entered into the constructions for determining lines and points, referred to a co-ordinate plane, by parallel lines perpendicular to that plane, we have in perspective projection the additional elements of the convergence of the projecting lines, or rays, intersecting the plane at different angles, depending conjointly on the distance of their point of convergence from the original lines, and from the plane. This variation in the conditions necessitates a different course of proceeding: in the former kind of projection the object of our constructions was to determine magnitudes; in that we are about to consider, our object is to delineate apparent and not real form.

68. The following definitions are here given to avoid unnecessary repetitions. The plane, on which the projection is supposed to be formed, and which is represented by the drawing board or paper on which the constructions are made, will always be termed *the plane of the picture.*

69. The point of convergence of the *rays*, or *projecting lines*, or the vertex of the pyramids of rays, will be designated as *the vertex.*

70. *The centre of the picture* is the point in which a line, through the vertex, perpendicular to the plane of the picture, meets that plane; and the length of this perpendicular, from the vertex to the centre of the picture, is *the distance of the picture or vertex:* this term will also be applied to the line itself when we have occasion to refer to it.

71. The *vertical plane* is one passing through the vertex, parallel to the plane of the picture.



72. Let XYZ . . . and UTES, in the figure, be the plane of the picture and the vertical plane; V in the latter being the vertex. Let BB'' be any straight line taken as an elementary original object: the rays from every point in BB'' will lie in one plane, the intersection, *b' b''*, of which with the plane of the picture will be the indefinite perspective projection or *image* of BB'': the projecting plane (9) passing through any original line BB'' and the vertex will also intersect the vertical plane in a line VD, parallel to *b' b''*. VD is *the director* of the original line.

73. If the original line BB'' were parallel to the plane of the picture, and therefore also to the vertical plane, its indefinite image and director would be parallel to the original line. But if BB'' be not parallel to the plane of the picture and vertical plane, it must intersect them both.

74. The point A, in which any original line cuts the plane of the picture, is termed its *intersecting point;* and D, in which it cuts the vertical plane, is termed the *station point* of that original line.

75. If a line VP be supposed to pass through the vertex, parallel to any original line BB'', it will cut the plane of the picture, if the original line itself be not parallel to that plane. This line VP is termed *the radial* of BB', and the point P, in which this radial cuts the plane of the picture, is *the vanishing point* of the original line.

76. If any original line pass through the vertex, its radial will coincide with it, and the point in which such a line cuts the plane of the picture will not only be its common intersecting and vanishing points, but also the common image of all points in the original line, and consequently of the entire line itself.

77. It follows from these theorems that the original line, its director, its radial, and its image, all lie in its projecting plane, and therefore its image must pass through its intersecting and vanishing points; while its director must pass through its station point: and that these four lines must form a parallelogram, unless the original line be parallel to the plane of the picture; in which case the director and radial will coincide in one line, lying in the vertical plane, parallel both to the original and to its image.

78. Let us now consider the projection or image of any point B in an original line BB'', and the situation of that image in the indefinite one of the line, according to the position of the point B.

If B be at A, the intersecting point of BB'' (74); B and its image *b** will coincide. If B lie in that part of AB which is on the contrary side of the plane of the picture to that on which the vertex is situated, its image *b* will lie between the intersecting and vanishing points, A, P, of the line: and if B be supposed to recede farther and farther from the former, the nearer to the latter will its image approach; so that the vanishing point is the *limit* of the successive images of points, farther and farther distant from the vertex, or it may be considered as the image of an infinitely distant point in the original line.

79. If the point B' be situated between the intersecting and station points of the line, its image *b'* will be on the contrary side of the intersecting point to that on which the vanishing point P is situated; and if B be the station point D of the original line, it can have no image, or its image may be considered at an infinite distance from the vanishing point in either direction.

80. If the point B'' lie on the contrary side of the vertical plane to that on which the plane of the picture is situated, its image *b''* will lie on the contrary side of the vanishing point to that on which the intersecting point is situated; and, as before, the vanishing point may be considered as the limit of the images in this direction; or as the image of a point in the original line at an infinite distance from the station point in either direction.

81. Let two or more original lines be conceived as lying in an original plane YZ, and suppose a plane W, which will be termed *the vanishing plane* of the original one, to pass through the vertex parallel to that original plane. The lines YZ, DE, in which an original plane cuts the plane of the picture and the vertical plane, are called the *intersecting and station lines*, respectively, of that plane; and the lines WP, TVT, in which the vanishing plane cuts the same two planes, are called the *vanishing line* and *parallel of the vertex* to that original plane.

82. The intersecting, station, and varnishing lines, and the parallel of the vertex, are all parallel to each other, these four lines being the mutual intersections of two parallel planes by two other parallel planes.

83. The intersecting and station points (74) of any original lines, lying in one plane, are points in the intersecting and station lines of that plane: and the vanishing points of the same original lines lie in the vanishing line of that plane; for the radials of the originals must lie in the vanishing plane of that in which the original lines lie: and these radials must form with each other, and with the parallel of the vertex, angles respectively equal to those which the original lines form with each other and with the intersecting or station lines.

84. The vanishing line and parallel of the vèrtex to any plane will be those also of all planes whatever which are parallel to the first: and the radial and vanishing point of an original line will be those also of all lines parallel to the first, whether they lie in one plane, or in different ones.

---

* We shall continue to employ the same conventional notation as before, designating an original point and line by capital letters, and their images by small, thus a b is the image of A B, and so on.

85. The perspective projections, or images, of any number of original parallel lines, will be either parallel lines, parallel to the originals (73), or will be lines passing through the respective intersecting points of those originals (77), and through their common vanishing point; and the points in which the indefinite images of original lines, not parallel, cut one another, will be those of the points in which the originals cut one another.

86. It has been shown that the image of a line is parallel to that line's director; if therefore two or more lines have a common station point, and, consequently, a common director, or if the station points of two or more lines lie in one director, the images of those lines in either case will be parallel lines; and in these cases only can original lines, not parallel, have parallel images.

87. The ratios which exist between the definitive images and the original segments of lines are easily deducible, either geometrically or analytically; but as these theorems do not lead to rules of frequent practical utility, we forbear, with one or two exceptions, entering into them. Let B″B represent a finite portion of an original line, bisected by the point B′, then the rays VB″, VB′, VB, and the radial VP of B″B, will be harmonical lines; the definite image of the original line will consequently be harmonically divided by the images *b*′, *b*, of B′ and B, and by the vanishing point P. Conversely if any segment of an indefinite image of a line be bisected by a point, the segment of the original line between its station point and the original of the image farthest from that station point will be harmonically divided by the originals of the other two points. If the point which bisects a finite line AB be the station point of that line, the image *a b* of AB will be bisected by the vanishing point P.

88. If an original finite line AB be parallel to the plane of the picture, its image *a b* will be to AB in the ratio of the *distance of the picture* (70) to the perpendicular distance of the plane, parallel to the picture in which AB lies from the vertex; and if AB be divided by a point D in any ratio, the image *a b* will be divided by *d*, that of D in the same ratio.

89. If an original plane figure be parallel to the plane of the picture, the image of that figure will be similar to the original: its periphery will be to that of the original, in the ratio of the *distance of the picture* to the perpendicular distance of the plane of the original figure from the vertex: and the area of the image will be to that of the original, as the squares of these lines. If therefore the distance of the picture be equal to that of the original parallel plane from the vertex, the image of an original figure in that plane will be equal, as well as similar, to the original: this may occur if the original plane coincide with that of the picture, or if the vertex be at equal distances from both, and lie between them; or if the vertex be infinitely and therefore equally distant from both on the same side.[*]

90. If an original plane, or planes, be parallel to the plane of the picture, their vanishing plane will coincide with the vertical plane: no such planes can therefore have any vanishing line.

91. If an original plane, or planes, be perpendicular to the plane of the picture, their vanishing plane will pass through the distance of the picture (70); consequently the vanishing line of such plane, or planes, will pass through the centre of the picture.

92. If an original plane pass through the vertex, its vanishing plane will coincide with it; the intersecting and vanishing lines will therefore coincide in one, as will also the station lines, and parallel of the vertex; and the images of all lines and plane figures, in such an original plane, will coincide in one line, that in which the plane itself cuts the plane of the picture.

93. The vanishing planes of two original planes will form the same dihedral angle that the original planes form with each other, and the line in which the vanishing planes intersect will pass through the vertex and be parallel to that in which the original planes intersect each other; it will, therefore, be the radial of this latter-named intersection. The intersection of the two vanishing planes, or this radial, will cut the plane of the picture in the vanishing point of the intersections of the original planes, which vanishing point will obviously be the intersection of the two vanishing lines determined by the two vanishing planes.

94. It follows, therefore, that the line in which two original planes cut one another will have for its vanishing point that in which the two vanishing lines of the original planes cut each other, and that the intersecting point of the common intersection of two original planes will be that in which the intersecting lines of those planes cut each other.

95. Every vanishing plane is supposed to have an *auxiliary* one, perpendicular both to it and to the plane of the picture, and therefore passing through the distance of the picture this auxiliary vanishing plane will cut the plane of the picture in an *auxiliary vanishing line* perpendicular to the principal one, and passing through *its centre*, and also perpendicular to the intersecting lines of the original planes. The line in which the auxiliary vanishing plane cuts the principal vanishing plane is termed the *principal radial* of the original plane, or planes, to which the vanishing plane pertains. This principal radial is obviously perpendicular to the principal vanishing line, and meets it in its centre, which will consequently be the vanishing point of all lines in the original planes perpendicular to their intersecting lines.

96. The principal radial will form, with the distance of the picture and with the auxiliary vanishing line, angles equal respectively to the complement of the angle, and to the angle itself, which the original planes make with the plane of the picture.

97. The *auxiliary radial* of any vanishing plane is one lying in the auxiliary vanishing plane, and perpendicular to the principal radial; this auxiliary radial is that of all lines perpendicular to the original planes, the common vanishing point of which is the point in which the auxiliary radial meets the auxiliary vanishing line. This auxiliary vanishing point is the image, or projection of the points in which the auxiliary radial intersects all the original planes to which the principal vanishing plane is common.

98. The auxiliary vanishing plane, being perpendicular to the original planes, as well as to their vanishing plane, and to the plane of the picture, will intersect those original planes in lines perpendicular to their intersecting lines, and parallel to their principal radial.

99. It follows from these definitions, that the vanishing lines of all planes perpendicular to one or more parallel original planes will pass through the auxiliary vanishing point of those planes.

100. If the original plane, or parallel planes, be perpendicular to the plane of the picture, their principal radial will coincide with the distance of the picture. Their auxiliary radial will be parallel to the plane of the picture; and the vanishing lines of all planes, perpendicular to the original planes, will be parallel to each other, and perpendicular to the vanishing line of the original planes.

101. If a circle be supposed, described in an original plane on the point, as a centre, in which the auxiliary radial cuts that plane, all lines touching that circle will be intersections with that original plane, of vanishing planes of other original planes, inclined to the first in a certain angle. The point in which any one of these tangents to the circle cuts the intersecting line of the first original plane, will therefore be a point in the vanishing line, to be determined for each such vanishing plane respectively, while the vanishing point of each such intersection in the original plane will be a second point in the vanishing line of the plane inclined to the former. Therefore this vanishing line will be determined, if these two points be found.

102. For if a right conical surface be imagined formed round the auxiliary radial as an axis, having the vertex for its apex, and its side forming with that axis the complement to the angle the secondary original planes form with the first; the vanishing planes of these secondary original planes will touch that conical surface in a line, which will be the principal radial of each such vanishing plane; and therefore each vanishing plane will cut the first original plane in a line tangential to the circular section of the conical surface by that original plane. Again, the point in which these tangents to the circular section cut the intersecting line of the first original plane, will be common to the intersections with the plane of the picture of each vanishing plane respectively, or to the vanishing line as above stated.

103. Constructions can be made, founded on these gen

---

[*] From this theorem the relation between perspective projection, and projection on a co-ordinate plane by parallel lines, either perpendicular or oblique to that plane, will be at once perceived; the latter being the *limit* of the perspective image, as the vertex of the converging rays may be supposed to become more and more distant from the original; or the former may be considered as a perspective projection, the vertex being at an infinite distance.

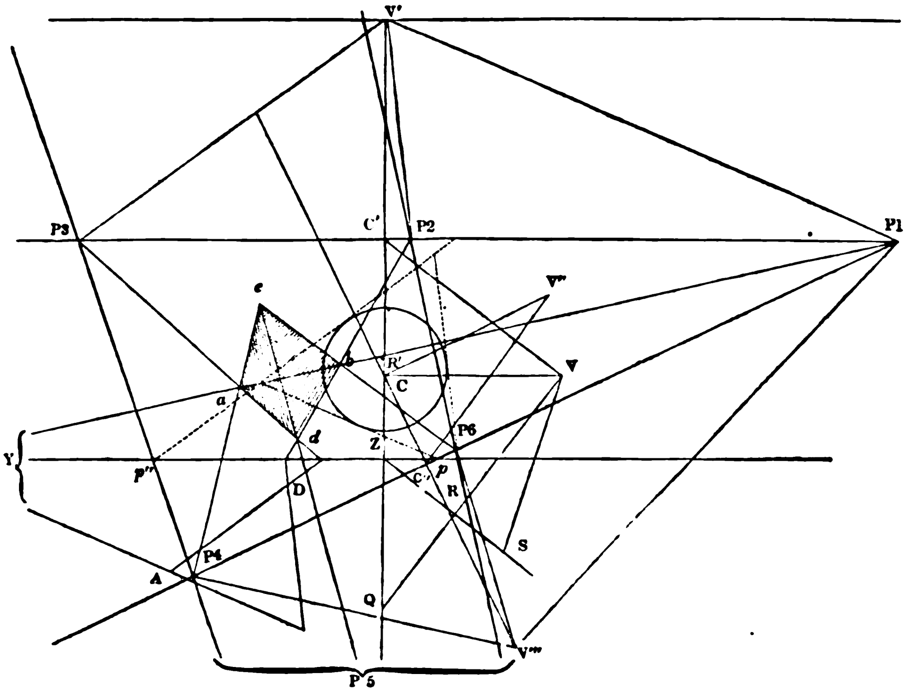
ral theorems, by which the perspective projection of plane figures, or solids, may be obtained on a plane, taken to represent the plane of the picture, and all other original or vanishing planes brought to coincide with it by being turned round on their intersections with each other, and with the assumed plane of the picture.

104. If an original plane be supposed turned round on its intersecting line till it coincide with the plane of the picture, the relations of lines in the plane to each other, and to the intersecting line, will not be affected by so doing. And if the vanishing plane of that original plane be also turned round on the vanishing line in the *same* direction, the same observation will apply to the radials of original lines in the original plane, which will preserve their original relative position to that vanishing line: these radials will be therefore parallel to the original lines respectively, when both they and the original lines are brought into the same plane.

105. Since the principal radial is perpendicular to the vanishing line, this radial will coincide with the auxiliary vanishing line when the vanishing plane is brought into the plane of the picture.

106. But if, as frequently occurs, the constructions must be made on the supposition that the original plane has been turned round on its intersecting line in one direction, and the corresponding vanishing plane turned round on its vanishing line in the contrary direction; the radials will not be parallel to the original lines on this supposition, when the two planes coincide in one. These radials must therefore be drawn, making the same angles with the parallel of the vertex and with the auxiliary vanishing line, that the original lines make with the intersecting line, and with lines perpendicular to it.

107. As an example of the application of the foregoing principles, let it be required to draw the perspective projection of a tetrahedron, of a given magnitude, its position with respect to the vertex and the plane of the picture being also given or assumed.



108. Draw YZ* at pleasure, to represent the intersecting line of one plane of the solid; and take any point C for the centre of the picture. Through C draw CV′ perpendicular to YZ for the auxiliary vanishing line of the plane (95). Also draw CV parallel to YZ, and equal to the given distance of the picture (70); this, and the following steps in the construction, being founded on the supposition of the auxiliary vanishing plane (95) being turned round on CV′, till it coincide with the plane of the picture. Make the angle CVC′ equal to the complement of that at which the plane of the tetrahedron is assumed to be inclined to the plane of the picture (96), VC′ will be the principal radial of the plane, and C′ the centre of its vanishing line; consequently a line P_3P_1, drawn through C′, parallel to YZ ([illegible]2), will be that vanishing line. Draw VQ, perpendicular to VC′, for the auxiliary radial, cutting VC′ the auxiliary vanishing line, in Q the auxiliary vanishing point of the plane of the original tetrahedron.

109. Draw ZR parallel to VC′ for the intersection of the auxiliary vanishing plane with the original one; R therefore, in which ZR meets VQ, will represent the point in which the auxiliary radial meets the original plane.

110. Make C′V′ in that line equal to C′V, and through V′ draw a parallel to YZ, which will represent the vertex and its parallel (81) brought into the plane of the picture by the turning of the vanishing plane on the vanishing line P_3P_1.

111. Draw the equilateral triangle ABD for the face of the tetrahedron in its given or assumed position with respect to the intersecting line of its plane and the centre of the picture: this construction implies that the original plane of that face has been turned round on YZ, in the same direction the vanishing plane was turned round in, on P_3P_1. Through V′ draw the radials of the sides of the triangle parallel to them, and cutting the vanishing line in P_1, P_2, P_3, the vanishing points of those sides; the perspective images of which being drawn through the intersecting and vanishing points of the sides respectively, will form the image *abd* of the given face.

112. If the original triangle had been assumed as lying between the intersecting and station lines of its plane, ABC would have been above the former line, and its image *abd* below it; if that plane be supposed turned round in the same direction.

If rays be drawn from V′ through A, B, and D, they will be found to pass through the images *a*, *b*, *d* of those points, and recourse must frequently be had to this mode of determining the image of a point in a line, when circumstances prevent the possibility of determining it by means of the image of another line, also passing through the original point. Or if the distances of any points in a line, as A, B, from its intersecting point, be set off from that point along the intersecting line, and the radial of the line be laid off along the vanishing line, from the vanishing point, of the original line; then lines drawn from the former points in the intersecting line to the point in the vanishing line, will cut the image of the original line in those of the points A, D.*

---

* In this and some subsequent figures, the bracket with a letter to it is intended to signify that that letter applies to the point of convergence of the lines so indicated: as for example in this figure, P_5 refers to the point in which P_3 P_4, and P_3 P_6 would meet. It must be observed also, that reference is in some places made to lines or points, not shown in the figures, to prevent confusion.

* Let Y be the intersecting point of an original line YA, and P its vanish-

113. By one or other of these principles, the images of any definite right lines, and therefore of any rectilinear figure, may be obtained. For one or more original lines may be always assumed as passing through one or more points the images of which are required; so that the indefinite images of the assumed lines will give those of the points sought, by its intersections with the images of other lines, in which those points lie: and these assumed lines may be so taken as to define the images with more precision, or to obviate the necessity of drawing radials of lines but little inclined to the intersecting lines of the planes in which they lie. ZR is the perpendicular distance of the point in which the auxiliary radial cuts the original plane from its intersecting line; R therefore is the centre of the circular section of the conical surface before alluded to (102). Make ZR' in ZV' equal to ZR: draw VS to make at V, with VR, the complement of the angle at which the faces of the tetrahedron are inclined to each other. From R', as a centre, with RS for a radius, describe a circle. Draw lines to touch this circle, parallel respectively to AB, BD, AD. Through the point *p*, in which the tangent parallel to AB cuts YZ, and through P_1, the vanishing point of AB, draw $P_1 P_4$, the vanishing line of the face of the solid meeting the face ABD in AB: and on the same principles $P_3 P_6$, $P_3 P_4$, the vanishing lines of the two remaining faces are found; then $P_4 P_5$, P_6, in which these vanishing lines intersect each other, will be the vanishing points (94) of the edges of the solid, and lines accordingly drawn from *a, b, d* to these points will complete the image of the tetrahedron.

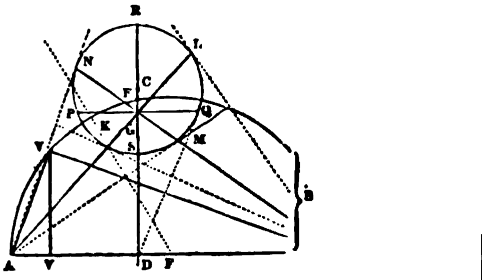
114. Simple as is the construction above described, for finding the vanishing lines of planes making any proposed angle with a given plane, it may frequently be avoided by availing ourselves properly of the symmetry of the solid to be delineated. Thus, in the example before us, after finding the image, *a, b, d*, of one face of the tetrahedron, we might have determined the image of the centre of that face by drawing those of the perpendiculars on each side of the triangle from the opposite angles; a line drawn through this centre and through Q would be the image of one, perpendicular to the plane of the triangle (97): this line would pass through the vertex of the pyramid, or through the angular point in which the other three faces meet, by finding the image of this point, which can be easily done by first determining the intersecting point of the perpendicular, and the intersecting line of any plane in which it lies; then lines drawn from *a, b,* and *d* to this image *e* would complete the figure.

115. When a vanishing line is obtained, it is frequently requisite to determine its centre and distance, or its principal radial; this is done by the construction employed to determine the vanishing line $P_1 P_3$. Thus, to determine the centre, &c. of vanishing line $P_1 P_4$, draw a parallel to it through C, making CV'' equal CV, the distance of the picture; also draw CV''' perpendicular to the vanishing line for its auxiliary one, cutting the former in C'' its centre. Make $C''V'''$ equal $C''V''$, the principal radial; then $V'''P_1$, $V'''P_6$, $V'''P_4$ being drawn, they will be the radials of the three sides, *a b, e b, e a,* of the face of the solid, and will be found, accordingly, to make angles of 60° with each other (83). The radial $V'''P_1$ will also be found equal to $V'P_1$, these lines representing one and the same line, only brought into the plane of the picture by the rotation of two different vanishing planes on their vanishing lines.

116. The perspective projection of a curve may always be found by means of the images of a sufficient number of points in the original, or by the projection of some inscribed or circumscribed polygon; if the curve be a plane one: in this case the image of a tangent to the original curve will be a tangent to the image of that curve. For if the image of the tangent meet that of the curve in more than one point, these points must be the images of points in the original curve through which the original of the tangent must pass; which is contrary to the supposition. But there are some theorems regarding the perspective projection of a circle, and constructions founded on them, which ought to be well understood by the draughtsman.

117. The rays from the circumference of a circle, obviously, form a conical surface, the section of which, by the plane of the picture, will be one of the conic sections. If the original circle, or base of the cone of rays, be parallel to the plane of the picture, the image will be a circle, the radius of which will be to that of the original in the ratio of the distance of the picture (70) to the distance of the plane of the original circle from the vertex (89).

118. If an original circle do not touch, or cut, the station line of its plane, its image will be an *ellipse* wherever the plane of the picture may be; unless the section by the plane of the picture happen to be a subcontrary one, an exception to which we shall recur on a subsequent occasion. If the station line be a tangent to the circle, its image will be a *parabola;* and if that line cut the circle, the image will be the opposite branches of an *hyperbola,* lying on contrary sides of the vanishing line of the original plane (80).



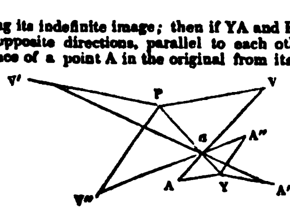
119. Let KNLM be an original circle, AB being the station line (81); the image of the circle will, in this instance, be an ellipse. Draw the diameter CD to the circle, perpendicular to AB; and let G be the point in CD through which the cords of the tangents from all points in AB pass, according to the well known property of the circle. Let V represent the vertex, the vertical plane being supposed to be turned round on the station line AB, till it coincide with the plane of the circle; VV' being the director perpendicular to the station line. Make DE, in DR, equal to the tangent to the circle drawn from D; bisect VE by a perpendicular, cutting AB in F; on F as a centre, with FV or FE for a radius, intersect AB in A and B, and draw lines through these points and through G; KL, MN will be the originals of the axis of the elliptic image of the given circle, wherever the plane of the picture may be assumed, and at whatever angle that plane and the vertical one be inclined to the plane of the circle.

120. If A, B be two points in AB, such that each is in the chord of the tangents from the other point produced, then from the properties of the circle, AE, BE will be equal respectively to the tangents AN, BL, drawn from those points: and the square on AB is equal to the sum of the squares on AN, BL, or on AE, BE. E therefore lies in the circumference of a circle described on AB as a diameter. Since the angle AVB, made by the directors of AL, BN, is a right angle by construction; the images of AL, BN will be perpendicular to each other, and parallel, respectively, to those of the tangents AN, AM; BL, BK having the same station points with the chords KL, MN. Again, since AL is harmonically divided in K and G, and BN in M and G, the image of KL will be bisected by that of G, and the image of MN will be also bisected by the image of G (87): hence those images being diameters to the ellipse, mutually bisecting each other, and parallel reciprocally to the tangents which are the images (86) of AN, AM, BK, BL, the images of KL, MN must be conjugate diameters, and since those diameters are perpendicular to each other, they must be the axes.

121. If V', the foot of the director VV', coincided with D, or if VV' were in the auxiliary vanishing plane, the perpendicular to VE would be parallel to AB, and PQ, SR would be the originals of the axes, which accordingly would be

---

ing point, YP being its indefinite image; then if YA and PV be drawn in any, whatsoever, but opposite directions, parallel to each other, YA being made equal to the distance of a point A in the original from its intersecting point,



and PV equal to the length of the radial of the line; then A, V being joined, AV will cut YP in *a*, the image of the point A. For however the lines YA, PV may be drawn, the triangles YA*a*, *a*VP will be similar; the antecedents YA, PV being constant, the consequents Y*a*, *a*P must be so likewise. When this principle is applied, the two parallels may be so taken that the line VA joining their extremities may cut YP at nearly right angles, and so define the point with precision parallel and perpendicular to the intersecting line. But in every other position of VV′, with reference to the circle, these axes must be oblique to that intersecting line, while the angles they form with it will vary according to the distance of V′ from D, and according to the length of the director VV′.

122. The points G and E will not be common to two or more concentric circles, the originals of the axes of the elliptic projections of concentric circles will not be in the same straight lines, nor will they have the same station points, except in the case of V′ and D coinciding, when the originals of the axes will be parallel and perpendicular to AB.

123. If AB touched or cut the original circle, the originals of the axes, &c., of the parabolic or hyperbolic projections might be found on the same principles: but as these curves do not often occur in practical perspective drawing, we shall not dwell on the subject.

124. The only solids with curved surfaces that need be considered are, the cylinder, the cone, and the sphere.

125. If a line be conceived to pass through the vertex, parallel to the axis of a cylinder, whether right or oblique, two planes passing through this parallel will touch the cylinder in two lines of its surface, also parallel to its axis, which will be the originals of the straight outline of the perspective projection, or image, of that cylinder.

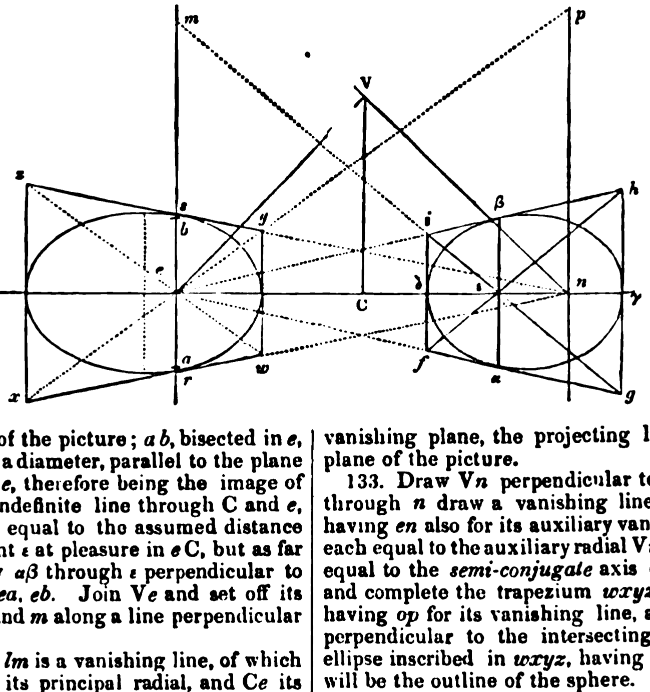
126. These two tangential planes will cut the plane of the base of the solid, or that of any section of it whatsoever, in two lines, which will be tangents to the curve of that section. And the parallel to tne axis through the vertex is obviously the radial of that axis, which, by its intersection with the plane of the picture, will determine the vanishing point of that axis; and this vanishing point, it must be remembered, is the image of the point, in any original plane, cutting the cylinder in which the two tangents to the curve of the section in that plane meet, which have been shown to be the originals of the outline of the solid.

127. If therefore the image of the base or of any section of the cylinder by a plane be obtained, lines drawn tangents to this image through the vanishing point of the axis will give the straight parts of the outline of the solid; these outlines must also be tangents to every other curve which is the image of any section of the original cylinder.

128. If a line pass through the vertex and the apex of a cone, and meet the plane of its base, or any other plane cutting the cone, two lines drawn through the point of intersection tangents to the curve of the section will be the intersections with that plane of two others passing through the vertex and tangential to the surface of the solid, and these two planes will touch the cone in lines which will be the originals of the outline of its image.

129. The ray just mentioned passing through the apex of a cone is analogous to the radial of a cylinder passing through the vertex, the cylinder being considered as a cone, with its apex infinitely distant.

130. If the line through the vertex and the apex of a cone, or the ray of that apex, be parallel to the plane of its base, or of any section, the tangents to the base lying in its plane, or in that of such section, must be drawn parallel to that ray, and the image of the apex will be the vanishing point of these parallel tangents.



131. Let C be the centre of the picture; ab, bisected in e, being given as the image of a diameter, parallel to the plane of the picture, of a sphere[*] e, therefore being the image of its centre (88). Draw an indefinite line through C and e, and CV perpendicular to it, equal to the assumed distance of the picture; take any point ϵ at pleasure in eC, but as far from e as convenient; draw $\alpha\beta$ through ϵ perpendicular to Ce, making $\epsilon\alpha$, $\epsilon\beta$, equal to ea, eb. Join Ve and set off its length each way from e to l and m along a line perpendicular to Ce.

132. By this construction lm is a vanishing line, of which e is the centre, Ve equal to its principal radial, and Ce its auxiliary vanishing line (95); l and m will obviously be the vanishing points of the diagonals of every square, lying in original planes having lm for their vanishing line, the sides of that square being parallel and perpendicular to the intersecting line of its plane; accordingly the quadrilateral $fghi$ is the image of such a square, lying in such a plane, and the line $\alpha\beta$ being made equal to the given image of a diameter of the sphere, $\alpha\beta$ and ab are the images of equal original lines parallel to the picture and equally distant from it, or both lying in a plane parallel to that of the picture. If therefore an ellipse be described in $fghi$, touching the sides in the points $\alpha\beta\gamma\delta$, and having its transverse axis in Ce, this ellipse will be the image of an original circle equal to a great one of the sphere, and having its plane parallel to that passing through the vertex and the centre of the sphere, or this original circle may be regarded as the oblique plan, on a plane parallel to it, of the section of the sphere by the vanishing plane, the projecting lines being parallel to the plane of the picture.

133. Draw Vn perpendicular to Ve, cutting eC in n, and through n draw a vanishing line perpendicular to en, or having en also for its auxiliary vanishing line; make no, np, each equal to the auxiliary radial Vn; make er, es,[*] in lm, each equal to the *semi-conjugate* axis of the ellipse last drawn, and complete the trapezium $wxyz$ as the image of a square having op for its vanishing line, and its sides parallel and perpendicular to the intersecting line of its plane. An ellipse inscribed in $wxyz$, having its transverse axis in en, will be the outline of the sphere.

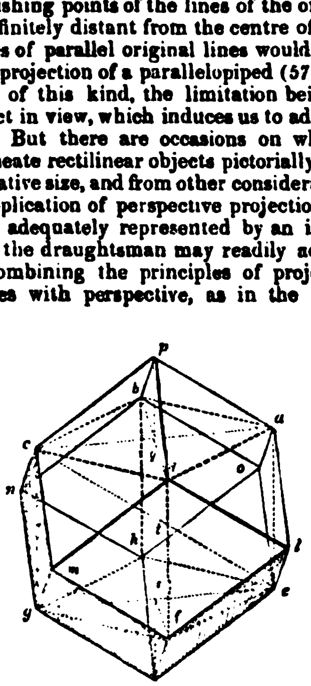
134. For n being the auxiliary vanishing point of the plane of the original of $fghi$, op is the vanishing line of all planes perpendicular to that original plane, and intersecting it in lines parallel to the plane of the picture. The original square of the quadrilateral $wxyz$ is therefore perpendicular to the plane of the original of $fghi$, or to the vanishing plane passing through the vertex and centre of the sphere. Now it will be seen that the conjugate axis of the ellipse in $fghi$ is the *oblique plan* (59) of the chord of the tangents from the vertex to the section of the sphere by the vanishing plane, which chord of the tangents must be a diameter of the small circle of the solid, constituting the original of its apparent outline; this small circle being the base of the cone of rays tangential to its surface (62), and having its plane perpendicular to that of the vanishing plane passing through the vertex and centre of the sphere; $wxyz$ is consequently the image of the square circumscribing the circular base, and the inscribed ellipse that of the circle itself, or this ellipse is the outline of the sphere.

---

[*] ab need not be perpendicular to the line ce; it is shown so in the figure, to avoid unnecessary lines; but as every diameter of the sphere which lies in a plane parallel to that of the picture is also parallel to that plane, ab may make any angle whatever with Ce.

[*] The points ra, sb, are not the same, though they cannot be distinguished in the figure

135. If the distance of the vertex (70) be supposed to be indefinitely great, compared to the magnitude of the object to be represented, the pyramid of rays may be conceived to become a prism, or the rays to be parallel. On this supposition the vanishing points of the lines of the original object would be indefinitely distant from the centre of the picture, and the images of parallel original lines would be parallels. The isometric projection of a parallelopiped (57) is obviously a limited case of this kind, the limitation being necessary from the object in view, which induces us to adopt that kind of projection. But there are occasions on which it is desirable to delineate rectilinear objects pictorially, which from their small relative size, and from other considerations, do not require the application of perspective projection, and which would not be adequately represented by an isometric one. In such cases the draughtsman may readily accomplish his purpose by combining the principles of projection on coordinate planes with perspective, as in the following example.



136. Let a hexagonal figure, *abcdefg*, be drawn, with the condition that each pair of opposite sides shall be parallel, and consequently equal; from the angles *a,c,f* draw lines parallel to the alternate sides, and meeting in a point *d*, and from the intermediate angles *b,e,g* draw lines parallel to the remaining sides respectively, and meeting in *h*. The figure thus formed will be the *orthographic* or *orthogonal* projection of a cube, under certain unknown conditions of inclination of the plane of projection to the projecting lines, and of these to the original planes of the solid.

137. The projections of the centres of each face of the cube, as *q*, may be found by drawing the diagonals, as *ac*, *bd*, and if lines be drawn through the centres of each pair of opposite faces, as *pr*, which lines will obviously be parallel to the edges of the solid, and perpendicular to the planes of the faces, they will pass through the vertices of right pyramids placed on each face. By making the altitude of these pyramids, as *pq*, equal to half the projection of the parallel edges *bf*, &c. of the solid, we obtain the remaining angles *l, m, n, o, p, r*, of the solid termed a rhomboidal dodecahedron, one diagonal of each face of which is one edge of the original cube.

138. By previously constructing the projection of a cube in the manner just described, the sides of which will furnish a scale of the ratio of the projections of any lines parallel to the edges of that cube, the projection of any parallelopiped may be obtained, and from this again the image of any symmetrical solid deduced. In this manner the forms of crystals can be drawn with the most perfect accuracy, and a most distinct conception obtained of them and of the relative position of their planes. And by analogous constructions diagrams of the theorems of solid geometry may be drawn, which would greatly facilitate the study of analytical geometry.

139. It has been stated that perspective projection is principally employed to furnish a pictorial outline of a building, machine, &c., or to convey an idea of an object of that description to the spectator, but to do this the perspective outline must excite in his mind the ideas of the real forms of that object in their relative situations, such as would be excited by the object itself, when viewed from a given point. But there are limitations to the apparent forms of objects, arising from the structure of the eye and the laws of vision, which the draughtsman must never lose sight of, when he practically applies the purely geometrical principles we have deduced, or otherwise he may produce an accurate projection of an object which would be perfectly unintelligible to an ordinary spectator; as the outline of the sphere, deduced in the preceding example, would be to an uninitiated eye.

140. Since the eye can only embrace at one time a very limited field of view, in order to see the whole of an object without changing the place of the eye, the spectator must not be nearer to it than a certain distance, for otherwise he would have to turn his head to see the successive parts, and at each such change of position the apparent forms of those parts just escaping from his view would undergo a considerable modification, arising from the structure of the eye itself. Few persons are aware of these modifications, owing to the effects of habit and the result of the judgment, which induce us unconsciously to assign the real and constant forms we know the parts of the object to possess to the apparent forms under which those parts are seen. Indeed it requires a considerable degree of abstraction and education of the eye to make the mind cognisant of the fact, that it is never the real form of an object that presents itself, a truth familiar to artists, who know that persons when first attempting to draw an object before them by eye, invariably draw it as they know it to be, and not as they really see it.

141. We have stated that the perspective projection of an object is rarely viewed from the precise point from which alone it ought to be viewed, so that the forms in the projection may suggest the ideas of the original forms whence they were deduced; consequently the outline should not in any part deviate greatly from what we may call the average form under which the true one would present itself to the eye. To effect this accordance the draughtsman must assume his point of view, or *vertex*, at such a proportional distance from the object itself, or from the imaginary model of it, that the rays from the points of it farthest apart, may not contain an angle greater than 60° at most, and, if circumstances allow of it, of not more than 45°. In short the pyramid of rays from an object to the vertex should be included within a cone the angle at the apex of which is not greater than that above named.

142. The distance of the vertex from the object being determined from these considerations, and its position with respect to the various parts of the original object decided by the conditions of the kind of view of that object it is proposed to delineate, the position of the plane of the picture should, generally speaking, be perpendicular to the axis of the cone or pyramid of rays before alluded to; but the following principles must determine more accurately its situation.

143. From the frequency of their occurrence under circumstances favourable for the observation, the eye is accustomed to the apparent convergence of long horizontal parallel lines, as in streets, aisles of cathedrals, long avenues of trees, or walls, &c., but perpendicular parallel lines are rarely if ever long enough to cause this optical effect. Now we have proved that the projections of parallel lines never can be parallel unless the originals are parallel to the plane of the picture; if therefore the draughtsman were to assume that plane *not* parallel to the vertical lines of a building, the convergence of the projections of these lines would strike the eye of a person looking at his drawing, as being at variance not only with his judgment of the real parallelism of the lines in question, but even with his daily uncultured observation. But there is another optical phenomenon regarding the appearance of long parallel lines, which we must briefly allude to, because it throws considerable light on the distinction between the apparent forms of objects seen by the eye, which forms are functions of the angles solely under which the original forms are seen, and the figures on a plane, resulting from the section by that plane of the pyramids of rays from those original forms, which sectional forms are functions of the arcs subtending those angles.

144. If a spectator stand opposite two or more long horizontal parallel lines, as those of the façade of a long building or of a garden wall, for example, he very palpably perceives the apparent convergence of these parallels in both directions, as they recede from him to the right and left: on reflection, he is therefore convinced that the apparent forms of the really parallel straight lines are curves, produced by the varying angles under which the equal ordinates between the parallels are seen, as they become more and more distant from the eye.

145. The parallel projections of such long horizontal lines which would result from the plane of the picture being

assumed parallel to the originals, would reassume their natural apparent curvature, if viewed from the correct vertex; but if not, their parallelism would offend the eye as being at variance with daily experience, and still more would any attempt to draw on a plane the apparent curvature of the lines in question be reprehended as being contrary to the verdict of the judgment, which decides that the originals, being straight lines, ought not to be represented by curves.

146. The draughtsman consequently must never assume his plane of the picture parallel to the longest side of a building, &c., however much he may be tempted to do so from the facility of making his constructions under this condition, when the projections of such a side would subtend at the vertex an angle of more than 15° or 20°.

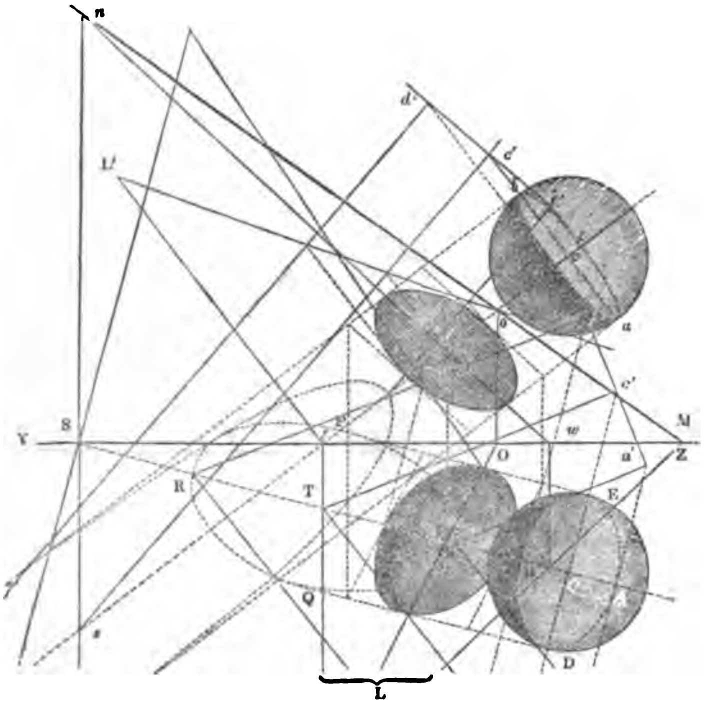
147. Keeping these conditions in view, the draughtsman may assume the distance of his picture, or its distance from the vertex, entirely according to his own convenience, since it is only the absolute magnitude of the image or projection which is altered by the different distances of the picture, the figure of the image being similar on all parallel planes, as long as the vertex and object remain the same. For the sake of facility of construction, he will generally assume his plane of the picture as coinciding with some principal vertical line of the object or model.

148. The *shadow* of any object is obviously the *projection* of it on a surface, by converging or parallel lines or rays, according as the luminary is supposed to be at a finite or at an infinite distance, as the sun may be considered to be as regards terrestrial objects. When therefore we have obtained the projection of an object by the principles just explained, they will also enable us to obtain the projection of its shadow on one or more planes or surfaces, as supposed to be cast by an artificial light or by the sun; the problem being simply to determine the projection of the intersection of a pyramid or prism of rays passing from a given or assumed point through the points of a projected object.

149. If the object be *perspectively* projected and the luminary be the sun, the vanishing point of the parallel rays, whose direction must be given or assumed, will represent the sun, since that vanishing point is the image of a point infinitely distant.

150. Although our power of forming correct conceptions of the true form of an object, as derived from a projection or pictorial representation of it, is much increased by the addition of light and shade, and of shadows of the object correctly projected by rules identical with those by which its outline was obtained, yet as soon as we thus approach the domain of a higher art, that of painting, the mathematical precision of the shadows we should obtain by our rules must yield to more important considerations connected with the arts alluded to. Hence it is that the draughtsman seldom applies the geometrical principles for finding the true shadows of the engine, building, or analogous object, the outline of which he has delineated, for at an early stage of his practice in drawing he ought to have acquired sufficient knowledge of art to be able to add to his outline the effect of light and shade without any gross violation of truth of nature, and with a better pictorial effect than he could ensure by geometrical rules. We shall consequently only give two simple examples relating to the projection of shadows, rather as affording additional illustrations of the principles of projections, than for any practical utility as regards the specific subject of shadows.

151. Let the line CS, *cs*, passing through the centre C, *c*, of a sphere, be given as the direction of the solar rays; it is proposed to determine the shadow of that sphere on the given plane LM*n*. It is obvious that the problem is to determine the section of the right cylindrical surface, formed by the system of parallel rays, which are tangential to the spherical surface, by the plane LM*n*; and that the great circle of the sphere passing through the points in which these rays touch it will be the base of the cylinder, and the boundary between the illuminated hemisphere and that in shadow.



152. Draw *cc′*, C*c′*, perpendicular to the projections of the ray, and make them respectively equal to the distances of the centre of the sphere from the co-ordinate planes; C′*s*, *c′*T, drawn through the points in which the given ray cuts the co-ordinate planes, will represent that ray brought into the co-ordinate planes by the turning round of its projecting planes on its projections; draw *a′b′*, *d′e′*, perpendicular to *c′*T, *c′s*, making them equal to the diameter of the sphere; then lines drawn through *a′*, *b′*, parallel to *c′*T, will represent the two rays, touching the surface of the solid and lying in the projecting plane of the given ray brought into the co-ordinate plane along with that ray: these lines will cut CT in QR, the vertices of the major axis of the elliptic outline of the shadow of the sphere on the co-ordinate plane. The conjugate axis QP will be given by drawing lines parallel to CT tangents to the projection of the sphere: for these last parallel tangents will be the boundaries of the projections of the cylinder of rays. Lines drawn through *a′*, *b′*, parallel to C*c′*, will cut *c*T in the vertices A, B, of the conjugate axis of the elliptic projection of the great circle, separating the illuminated hemisphere from that in shade; a diameter DE to the circular projection of the sphere, drawn through *c* perpendicular to CT, will be the major axis of this ellipse.

153. For the plane of the great circle, of which ADBE is the projection, is obviously by the construction perpendicular to the given ray, and the plane of this circle is cut by the projecting plane of the given ray CT in the original of AB,

while the diameter DE is the projection of the intersection with the plane of the same great circle, by a plane passing through the given ray CS, *cs*, and perpendicular to the plan-projecting plane (9) of the given ray. This perpendicular plane must therefore be the elevation-projecting plane of the given ray.

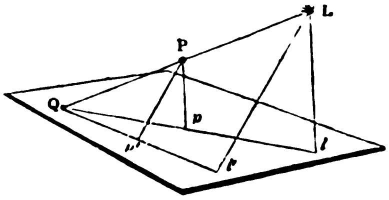
154. By the same construction applied to the other projection, the elliptic elevation *adbe*, of the circle separating the light and shade on the sphere, and the elliptic shadow of the sphere on the vertical co-ordinate plane, may be obtained.

155. It is clear that in this example the two elliptic outlines of the shadows of the sphere on the co-ordinate planes, must cut YZ in two common points; because the segments of the ellipse on either side of YZ of each outline is the projection on the one co-ordinate plane of that portion of the cylinder of rays which forms on the other co-ordinate plane the portion of the outline of the shadow on the same side of YZ. *t*L, perpendicular to YZ, is the trace of the elevation projecting plane of CS, *cs*; *o*, O, is the point in which this same plane cuts the trace of the given plane, consequently LO is the plan of the intersection of those two planes, and T, in which this line is cut by the plan of the ray CS is the intersection of that ray, and the given plane; the elevation *t′* of the same intersection may be obtained by applying the same constructions to the other traces and projections.

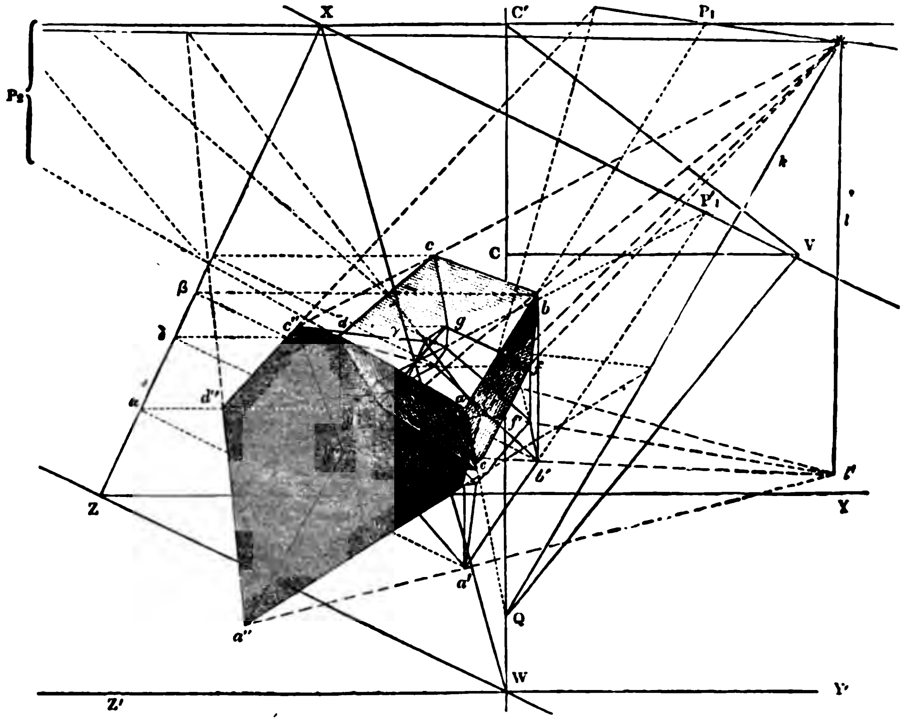
156. The two pair of parallel planes, which are respectively perpendicular to the co-ordinate planes, and therefore to each other, and which are parallel to the given ray, touch the sphere in the points A, *a*; B, *b*; D, *d*; E, *e*. These four planes will be cut by the plane LM*n* in a parallelogram, the sides of the projections of which must be parallel to those of the ray CS, *c*, *s*, and to the lines LO, *wn*. Draw *t*L′ perpendicular to *ot*, and make *t*L′ equal to *t*L; join *o*L′, which will represent the intersection of the projecting plane with LM*n*; draw lines through *d′*, *e′*, parallel to *c′s*, and from the points in which these parallels cut *o*L′ draw parallels to L′*t* to cut *ot*; again lines drawn through these last intersections parallel to *wn* will be the two sides of the elevation of the rectangle above mentioned; the parallel tangents at *a* and *b* will complete the figure; and *ot*, *wn*, will cut the opposite sides in the points in which the elliptic outline of the shadow of the sphere will touch those sides, or the points which represent the shadows of *d*, *e*, *a*, and *b*.

157. The plan of this parallelogram may be determined in the same manner, or by the other constructions explained for determining the projections on the other co-ordinate plane from those already determined on the first, and which are sufficiently indicated in the figure to render further description of them unnecessary.

158. If L represent a luminous body, and P a point, then



by imagining a plane to pass through them, the intersection of that plane with the plane on which the shadow is cast will cut the ray LP in Q, the shadow of the point. To determine this intersection, we have only to draw two parallel lines through L and P, in *any* direction, and determine the points *l* and *p*, or *l′*, *p′*, in which these parallels meet the plane of the shadow: then *l p*, LP being drawn, they will cut each other in Q, the shadow of the point. This is the principle employed in the following construction.



159. Let *a b c d e f g* be the perspective projection of a cube, C being the centre of the picture, CV the distance of the picture, P₁ X the vanishing line of the face *a b c d*, and Y Z its intersecting line; while Y′ Z′ is that of the face *e f g*, parallel to the former. Let Y X and W Z be given as the vanishing and intersecting lines of a plane, on which the shadow of the cube, as cast by the luminous body * given in position, is to be determined.

160. XZ, XW, being drawn, will represent the lines in which the plane of the shadow intersects those of the parallel faces of the solid (94). If we suppose planes parallel to that of the picture to pass through the various points of the cube, as *a*, these will intersect the two original planes in lines, as *a α*, *a a′*, parallel to Y Z, Z W, and a line, *aa′*, through the point of the cube, parallel to the auxiliary vanishing line, will meet *a a′* in the point *a′*,* which will be the oblique projection of the point *a* on the plane of shadow. Therefore by drawing lines through the points *a*, *b*, *c*, *d*, parallel to Y Z, to cut X Z in *α*, *β*, .. *δ*, then lines parallel to W Z, through *α*, *β* … *δ*, will cut lines parallel to WC′, drawn through *a*, *b*, *c*, *d*, in the oblique projections of those points on the plane of the shadow, and by referring *e*, *f*, *g* … to WX, in the same way, we obtain the oblique projections of the other angles of the cube.

161. Since the sides of the cube *ab*, *cd*, *ef*, &c. are parallels, their oblique projections will be parallels (59), consequently the images of these parallels *a′b′*, *c′d′*, *e′f′*, &c. will have a common vanishing point P′₁ in the vanishing line of

---

* That is to say, *a′* is the *perspective image* of the oblique projection of the original point of which *a* is the perspective image.

the plane in which the oblique projections lie; for the same reason, *a'd'*, *b'c'*, *f'g'*, &c. will have a common vanishing point P'_2 in YX. Now it is obvious that the vanishing points P'_1, P'_2 are, by an extension of the principle, the oblique projections on the plane of the shadow of the vanishing points P_1 P_2 of the original sides of the cube; consequently the former may be determined from the last-named vanishing points by simply drawing lines through them parallel to WC to cut YX in P'_1, P'_2.

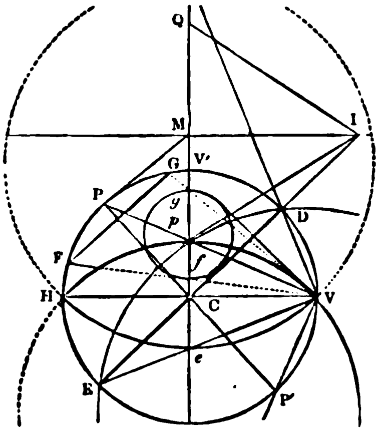
162. If *k* had been given as the image of the point in which a line through the luminary perpendicular to the plane YZ met that plane, the image * of the luminary would be determined by making *k**, drawn to the auxiliary vanishing point Q, the image of the given perpendicular height of the luminary above the original plane. A line through * parallel to WC' will meet C'*k* produced in *l*, the oblique projection of the luminary on the plane YZ.* Its oblique projection *l'* on the plane of the shadow may be either determined as those of *a*, *b*, *c*, *d*, &c. were, or by drawing a line, as *al*, at pleasure, to cut the vanishing line XP in some vanishing point; this vanishing point may be transferred to XY by a parallel to CW; then a line drawn through *a'*, the oblique projection of *a*, to this transferred vanishing point, will cut **l* produced in *l'*, the oblique projection of the luminary on the plane of the shadow.

163. Draw lines through *l'* and through the oblique projections *a'*, *b'*, *c'*, *d'*, *e'*, &c. intersecting each such line by the luminous ray **a*, **b*, **c*, &c. in the shadows *a''*, *b''*, *c''*, &c. of the angles of the cube, and these points being joined, the figure thus produced will be the image of the shadow of the cube on the plane as proposed.

164. The oblique projecting lines *aa'*, &c. were assumed parallel to the picture and its auxiliary plane, simply for facility of construction, or else the points *a*, *b*, *c*, *e*, *f*, &c. might, as well as the luminary, have been projected on the plane of the shadow by lines in any direction, provided these lines were parallels according to the above principle (158).

165. Draw lines through * and P_1, P_2, and Q, the vanishing points of the sides of the cube; then the images, as *a''b''*, *c''d''*, *e''f''*, of the shadows of the parallel lines of the original solid will meet in a point in the corresponding line drawn through * and the vanishing point of those originals. For the planes passing through * and the parallels *ab*, *cd*, *ef*, &c. must intersect in a common line, passing through * and parallel to those originals: this common intersection will therefore have the same vanishing point, P_1 as those originals: the line *P_1 represents that common intersection. Now the shadows *a''b''*, *c''d''*, *e''f''* are the intersections of the before-mentioned planes by another, namely, by the plane of the shadow, and these intersections, *a''b''*, *c''d''*, &c., must meet each other in a point in *P, the common intersection of the planes passing through * and the original lines. The same reasoning applies to the other shadows of the corresponding parallel sides of the cube.

166. In the article Map the different modes of referring portions of the surface of a sphere to a plane have been explained; we shall here confine ourselves to giving a few practical theorems on this subject as connected with the subject before us.



167. In this figure the circle EFGDV is the intersection of a sphere with the plane of the picture, supposed to pass through its centre. The vertex is supposed to be in the surface of the solid, in a diameter perpendicular to the plane of the picture; C is therefore the centre of the picture, and CV the distance of the vertex, brought into the plane of the picture by the auxiliary vanishing plane (95) being turned round on the diameter V'V', which is an auxiliary vanishing line. It is obvious that if any great circle, the plane of which passes through the vertex, be turned round on the diameter ED, which it forms by its intersection with the plane of the picture, till the two coincide, the vertex will coincide with the extremity of a diameter PP at right angles to the former ED.

168. It is shown [Subcontrary] that under this condition of position of the vertex, every original circle of the sphere, whether a great or a small one, is perspectively projected into a circle; and since a circle is given, when either its centre and radius or three points in its circumference are found, the constructions for drawing these projections are simple and direct.

169. Let HV be the intersecting line of a great circle, supposed to be inclined to the plane of the picture in a given angle; to find its projection. Draw V'V' perpendicular to HV for the auxiliary vanishing line (95) of the given plane. Draw the diameter ED to make the angle V'CD equal to the given one. ED will be the intersection of the original and auxiliary vanishing planes, brought into the plane of the picture along with the vertex V. Draw the rays VD, VE, to cut the auxiliary vanishing line in *d* and *e*, then *d* and *e* will be two points in the projection of the circle, while that image must pass through the points H and V (78). Since EVD is a right angle, and the image passes through V, *ed* must be a diameter of that image, as is indeed obvious from its bisecting the chord HV at right angles.

170. Let FG be the diameter of a small circle, produced by its intersection with the auxiliary plane, the small circle in this figure being assumed parallel to the plane of the large one last projected: by drawing VF, VG, to cut CV' in *f*, *g*, we get the diameter of the circle which is the image of the original one.

171. Let PP, perpendicular to ED, FG, be the common diameter to a series of great circles or *meridians;* that common diameter lying in the auxiliary vanishing plane, and being brought along with it into the plane of the picture. The points *p*, *p** will obviously be the images of the extremities of this common diameter, and the images of all these meridians must pass through *p*, *p*. To draw the image of such a meridian forming any proposed angle with the auxiliary plane, which is obviously that of one such meridian—Draw PM perpendicular to PP, to cut CV' produced in M; through M draw a line perpendicular to CV'. This line MI will be the intersecting line of a plane tangential to the sphere at the extremity of the given diameter of the meridians. Now this plane will be cut by the meridians in lines meeting in P and making plane angles with each other, measuring the dihedral angles at which the meridians themselves are inclined to each other. Make MQ in CV' equal to MP, then Q will be the point P brought into the plane of the picture by the tangential plane being turned round on MI. QI, drawn to form the proposed angle with IIQ, will represent the intersection of the tangential plane with that of the meridian; the diameter ED drawn through I will consequently be the intersecting line of the plane of the meridian: a circle drawn through E, D, *p* and *p* will be the image of that meridian.

172. The point I may however be found more directly, for since the angles VHP MPV are equal, VC*p*, VPH both right angles, and HVP common to the two triangles VCP, VHP, the remaining angle V*p*C, or P*p*M, is equal to PHV or to MP*p*, therefore the triangle MP*p* is isosceles or MP is equal to M*p* or to MQ by construction. Hence the angle M*p*I is equal to MQI, or to the angle of inclination of the two meridians, and *p*I may be drawn accordingly at once to make that proposed angle with CM. If the planes of the meridians are mutually perpendicular, the point I will be at an infinite distance from M; HV perpendicular to CM will in this case be the intersecting line of the second

---

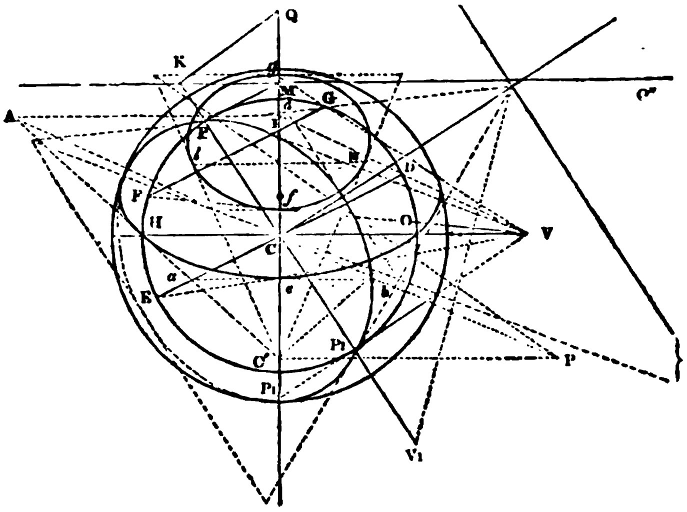
* For since **k* is perpendicular to the original plane YZ, and **l* is parallel to the auxiliary vanishing line, and therefore to the auxiliary vanishing plane, a plane passing through these lines must be perpendicular to the original plane, and parallel to the auxiliary vanishing plane; it must consequently cut the original plane in a line perpendicular to its intersecting line; this intersection will therefore have C' for its vanishing point.

* The other *p* is out of the figure, being the intersection of VV, with duced.

meridian; and a circle drawn through H, V, *p*, *p* will be its image.

173. By these constructions, the meridians and parallels of latitude for a map on the *Stereographic* projection can be drawn, whether the axis of the globe be parallel or inclined in any proposed angle to the plane of the picture.

174. When the vertex is without the surface of the sphere, all the circles on the surface are projected into right lines or ellipses, and the axes of these ellipses are readily found by the principles of perspective projection: the plane of the picture is assumed, as before, passing through the centre of the sphere, and vertical to the line joining the centre and vertex. Let EPDO be the circle, formed by the intersection of the plane of the picture with the spherical surface; CV is the assumed distance of the picture, the auxiliary plane being turned round on the auxiliary vanishing line C′M: ED, FG being the intersections of any given great circle, and of a small one parallel to it, with the auxiliary plane. The planes of these circles being inclined to that of the picture in an angle equal to MCD.



175. Through V draw VC′ parallel to DE, to cut the auxiliary vanishing line in C′, the centre of the vanishing line of the original planes of the given circles, C′P drawn parallel to HO, the intersecting line of the plane will be the vanishing line, and if C′P be made equal to C′V, the principal radial, P, will be the vanishing point of all lines making angles of 45° with the intersecting line; consequently PA drawn through C will be the indefinite image of the diagonal of the square circumscribing the original circle. Draw the rays VD, VE, to cut the auxiliary vanishing line in *d*, *e*; through these points draw AB, *ab*, parallel to HO, and draw C′A, C′B, through H and O; then the rhombus AB*ab* will be the image of the circumscribing square, and the elliptic image of the circle will touch its side in the points H, *o*, *d*, and *e*; *de* is the conjugate axis of this ellipse (121); the major axis will therefore bisect *d e* at right angles. Produce FG to cut C′M in I, through I draw a line parallel to HO for the intersecting line of the plane of the given small circle, set off on it each way from I the half of FG, then lines drawn through these points thus marked to C′, will be the images of the two sides of the circumscribing square which are perpendicular to the intersecting line (95); the images *f*, *g*, in the other two sides, are found by the rays VF, VG; lines through *f* and *g* parallel to HO will complete the image of the circumscribing square; the elliptic image must be drawn accordingly to touch its opposite sides in *f*, *g*, *l*, and *n*, *fg* being the conjugate axis.

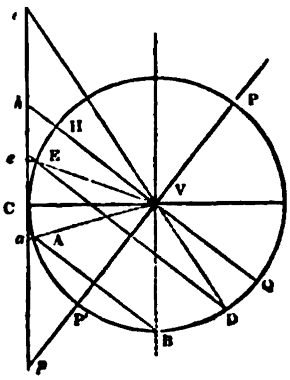
176. Draw the diameter PP perpendicular to DE, as the common diameter of a series of meridians, the planes of which are perpendicular to that of the great circle *d*H*e*O, this common diameter lying in the auxiliary plane, and being brought with it into the plane of the picture; *p*, *p*, will therefore be the images of the poles of the circles ED, FG, &c., and the images of all the meridians must consequently pass through these points.

177. The intersecting line of the plane of any of these meridians making any proposed angle, equal to MQK, with the auxiliary vanishing plane, may be found by the same construction employed for the same purpose in stereographic projection. Let ED be taken to represent such an intersecting line found by the construction alluded to. Make CV_1 equal to the distance of the vertex, make the angle CV_1C'' equal to MQK, or to that which the original plane makes with the auxiliary plane, VC'' cutting the auxiliary vanishing line CC″, produced in C″, the centre of the vanishing line of the plane, which vanishing line must accordingly be drawn through C″ parallel to P_1P: by means of this vanishing line and its principal radial V_1C'', the image of the circumscribing square can be found, and the ellipse drawn tangents to its sides.

178. The cone of rays from the vertex, tangential to the surface of the sphere, will be cut by the plane of the picture in a circle concentric with EPDO, and the diameter of this outline of the sphere will be found by drawing tangents from V to the circle EPDO, to cut the auxiliary vanishing line in its vertices. Now the elliptic images of all great circles must touch this outline, since the originals must touch that of the outline; consequently the major axes of the elliptic images of such great circles must be diameters of this circular outline: these axes may be determined by the properties of the curve from the data before obtained.

179. When this projection is used for the construction of maps, the opposite concave hemisphere, beyond the plane of the picture, is represented; but if the sphere be intended to be projected as an object, the convex surface towards the vertex and bounded by the visible outline should be drawn.

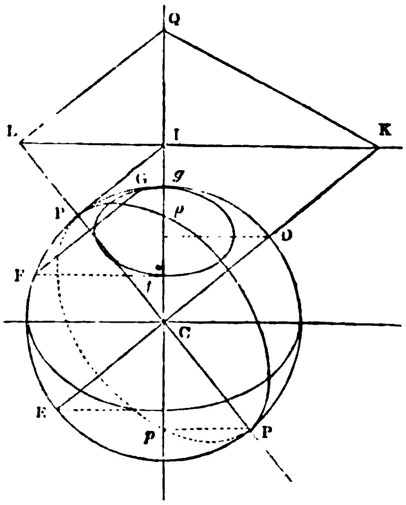
180. When the vertex is at the centre of the sphere, all great circles are projected into right lines (93), and the small circles are projected into conic sections. Let the circle AHPD represent the intersection of the sphere with a plane passing through the distance of the vertex VC, and therefore perpendicular to the plane of the picture: If PP_1 be the common intersection of a series of meridians, the projections of these great circles will be right lines passing through *p*, the projection of P, or through the intersection of PP with the plane of the picture; and these projections of the meridians will cut the straight line [illegible] the intersection of the plane of the equator HO with the plane of the picture in the tangents of the angles the meridians



make with the auxiliary plane AHPO, V*h* being radius. Hence the constructions for drawing these meridians are extremely simple.

181. Let AB, ED, &c., represent parallels of latitude; these will constitute the bases of so many right cones, having the vertex V, or the centre of the sphere, for their common vertex, the projections of these small circles will be ellipses, parabolas, or hyperbolas, according as the opposite slant sides of the cones are inclined or parallel to the plane of the picture. The projection of ED will be opposite hyperbolas (118), *e*, *d* being the vertices of their major axis. If BV be parallel to *p d*, the projection of AB will be a parabola, otherwise an ellipse, provided VB meet the plane of the picture on the same side of C that VA meets it. All these curves will have the auxiliary vanishing line for their common major axis; they can therefore be drawn with facility either by constructions derived immediately from the theorems relating to the curves as sections of the line, or else points in their projections may be found by the simplest principles of perspective projection.

182. When the circles of the sphere are projected on a plane by lines perpendicular to it, the position of the plane is immaterial, the sections of the cylindrical surfaces formed by the projecting lines being unchanged by any variation in the position of the plane, provided it be vertical to the projecting lines. However, to indicate the analogy between the principles employed in the constructions in this case, and those that have preceded, we shall suppose the plane of the picture, or the co-ordinate plane, to pass through the centre of the sphere.



183. Let EFGD be the great circle that is the intersection of the plane with the solid, and also representing any other which is perpendicular to the co-ordinate plane, supposed to be turned round on their common diameter till they coincide. If PP, supposed to be in a plane perpendicular to that of the projection, be the common intersection of any series of meridians, P*p*, P*p*, will be the projecting lines (1) of its vertices brought into the co-ordinate plane by the rotation of the plane in which these three lines lie, on CQ its trace (18). The projections of all these meridians must therefore pass through *p* and *p*. Now if the same construction be made in this case as was explained in the corresponding problem in the stereographic and globular projections (171), we shall obtain ED as the intersecting line (81) or trace (18) of the plane of a meridian forming any proposed angle IQK with the auxiliary plane, and ED will be the major axis of the elliptic projection of that meridian (49); the semi-conjugate is the cosine of the angle at which the plane of the circle is inclined to that of projection.

184. The other methods of delineating maps, on the supposition of the *development* of a conical or cylindrical surface, supposed to touch the sphere, are foreign to the subject of projections, and consequently are not here introduced.

PERSPICILLA, Mr. Swainson's name for a genus of *Water-chats* (*Fluvicolinæ*).

Generic Character.—*Bill* long, compressed on the sides. *Nostrils* naked. *Wings* rounded, broad; the scapular quills as long as the primary quills. *Tarsi* very long, smooth. *Tail* rather short. (Sw.)

Example, *Perspicilla leucoptera*, Sw.

Locality, South America.

PERSPIRATION, CUTANEOUS. [SKIN.]

PERTH. [PERTHSHIRE.]

PERTHSHIRE, a large and central county in Scotland, bounded on the north by the shires of Inverness and Aberdeen; on the east by Forfarshire; on the south-east by Fifeshire (from which, in one part, it is separated by the Frith, or æstuary, of the Tay), and by Kinross-shire; on the south by Clackmannan and Stirling shires; on the south-west by Stirling and Dumbarton shires; on the west by Argyleshire; and on the north-west by Inverness-shire. The form of the shire is compact; its greatest length from north to south is from the border of Inverness-shire, north by east of Loch Garry, to Balguir Muir, west of Stirling, 53 miles; the greatest breadth from east to west is from the border of Forfarshire, between Meigle and Glamis, on the road between Perth and Forfar, and the border of Argyleshire, near Loch Lydoch, 62 miles; or from the border of Fifeshire, near Abernethy, to the border of Argyleshire, north-west of Loch Lomond, which is also about 62 miles. (*Map of Scotland*, published by the Society for the Diffusion of Useful Knowledge.) A small detached portion of the county lies on the northern shore of the Frith of Forth, between the shires of Fife and Clackmannan, and another small detached part is surrounded by Stirlingshire; while a small detached portion of Forfarshire is included in the boundaries of Perthshire. The area of Perthshire is estimated at 2538 square miles, or 1,624,320 English acres. (Playfair's *Description of Scotland*, M'Culloch, *Statistical Account of the British Empire*, gives the area at 2588 square miles for the land, and 50 square miles of lochs.) The population in 1801 was 126,366; in 1811, 135,093; in 1821, 139,050; and in 1831, 142,894 (*Pop. Returns*), giving about 56 inhabitants to a square mile. This population is however very unequally distributed; twenty parishes in the western and northern parts of the county, comprehending about two-thirds of the area of the county, have a population of 44,902, giving from 26 to 28 inhabitants to a square mile; while in the remaining small but numerous parishes of the south-east the population may be estimated at from 110 to 120 to a square mile. The county lies between 56° 2′ and 56° 57′ N. lat., and between 3° 2′ and 4° 50′ W. long. Perth, the capital of the county, is on the river Tay, in 56° 24′ N. lat., 3° 26′ W. long.; 43 miles from Edinburgh by Queensferry and Dumfermline, and 442 miles from London.

In *The Beauties of Scotland* (Edinb. and Lond., 1805-8), and in the *Gazetteer of Scotland*, compiled by Messrs. Chambers (Edinb., 1832), the dimensions and area of the county are exaggerated in a most extraordinary manner; the length (from east to west) and breadth are given at 77 and 68 miles respectively, and the area at 5000 square miles, or 3,200,000 acres.

Surface and Geological Character.—The whole of the county except the immediate vicinity of Perth is hilly, if not mountainous. The Ochill Hills or Mountains traverse the south eastern part between the Forth and the Tay; they rise in some parts to an elevation of more than 2300 feet above the level of the sea. The Grampians form the northern and north-western boundary of the county, separating it from Aberdeen and Inverness shires. Glass Mluel, Benu-arn-More, Scarcsoch (3390 feet), and Bruoch-Carruvan are in this part of the range. The western half of the county is overspread by the mountains of the Western Highlands, among which are Ben Venue, Stuich a Chroin (3171 feet), Ben Ledi (2863 feet), Ben Vorlich (3180 feet), Ben More (3819 feet), Ben Lawers (3945 feet), Schihallien or Schiehallion (3513 feet), Ben Chualach, Ben Vollich, and Dunichmore. Cairn Gower in the Ben y Gloe Mountains in Athol Forest, south of the Grampians, has an elevation of 3690 feet. The Sidlaw Hills are on the east side of the county near Forfarshire; Dunsinnan or Dunsinane hill, one of these, immortalized by Shakspere in his 'Macbeth,' is 1114 feet above the level of the sea, and nearly 800 feet above its base. Upon its oval and conical summit, 507 feet in length by 267 medium breadth, Macbeth erected his castle. Birnam hill, near Dunkeld, is stated by some authorities to be above 1500 feet high.

These mountainous districts are intersected by long winding narrow vales, or 'glens,' through which the streams flow, or by 'straths,' or wider valleys. Strathallan in the south part of the county separates the Ochill Hills from the mountains of the Western Highlands; Strathearn extends across the centre of the county from west to east; Strath Tay, and lower down Strathmore (which last extends eastward into Forfarshire, or rather through it), form the valley of the Tay; and Strath Airdle is in the north-eastern part of the county. In the northern part of the county are Glen Shee and Glen Beg, Glen Fernal, Glen Tilt, Glen Bruar, and Glen Erochkie. In the west are Glen Lyon, Glen Lochy, Glen Dochart, Glen Falloch, and Glen Artney. Glen Tilt communicates with Strath Tay by the well-known pass of Killicrankie. The road here is cut out of the side of one of the contiguous mountains; and below it, at the foot of a high precipice, in the bottom of the ravine, the river Garry dashes along.

The north-western and northern parts of the county belong to the great primitive district of the north of Scotland. Granite is found underlying the peat of the extensive waste of Rannoch Moor in the west part of the county; but the predominant rock in this district is mica-slate, skirted by clay-slate and chlorite-slate, both which pass insensibly into mica-slate. Schiballien, Ben Lawers, the hills round Loch Tay, and many of the mountains in the Grampian range are composed of mica-slate, intermixed with hornblende-slate and quartz-rock, and in some parts with a small portion of crystalline limestone. Chlorite-slate is the predominant rock of Craig Cailleach, near Killin, intermixed however with rocks consisting of hornblende and felspar, and of micaceous schist mixed with hornblende. The rocks about Aberfoyle consist of irregular alternations of grauwacke and grauwacke slate with clay slate; the beds are in various positions and elevated to high angles: quarries of fine roofing clay-slate are wrought here. On approaching the shores of Loch Cateran, or Catrine, the rock presents an appearance approaching to that of mica-slate. At Ben Ledi the structure still more resembles mica-slate; and beyond this, east of Loch Lubnaig, true mica-slate occurs, and occupies the whole district as far as Perth. A highly elevated range of breccia may be traced in various places, separating the primitive district from the secondary district in the south-east of the county. (*Geological Transactions*, vol. ii., pp. 436, 446; vol. iv., pp. 128, 129.)

The district to the south and east of the breccia is occupied by beds of sandstone. Basaltic rocks may be traced in a north-east direction, extending, though not continuously, through this district, sometimes capping hills of sandstone, sometimes forming entire hills of considerable magnitude, and sometimes irregularly interstratified with sandstone beds. The Ochill Hills in the south-east part of the county consist chiefly of porphyry and amygdaloid; and the Hill of Kinnoul near Perth is an amygdaloid containing numerous nodules of agate and carnelian. M'Culloch's *Statistical Account of the British Empire.*) Some portions of the county near the south-eastern border are comprehended in the coal-field of Fifeshire (M'Culloch, as above); and some authorities mark a narrow district extending south-west from Camry, or Comrie, near Crieff, in the direction of Dumbarton, as occupied by the coal-measures and associated formations. ('Map' given in *Geological Transactions*, vol. iii.)

Hydrography.—This county is almost entirely comprehended in the basin of the Tay. A small portion on the south-west side, drained by the streams which flow into Loch Lomond, belongs to the basin of the Clyde; and the more important district of Menteith in the south is included in the basin of the Forth.

The Tay rises in a small loch or lake near the extreme western part of the county on the border of Argyleshire, and flows east and east by north 20 miles, through Loch Dochart into Loch Tay. In this upper part of its course it does not take the name of Tay, but is known as the Dochart. It is joined just before it enters Loch Tay by the Lochy, or Lochie, which rises a little to the north of Loch Dochart, and has a circuitous course of about 16 miles. Loch Tay is a long narrow lake embosomed in mountains, having Ben Lawers near its north-western shore; its length from south-west to north-east is about 14 miles; its average breadth is about one mile. (*Map of Scotland*, published by the Society for the Diffusion of Useful Knowledge.) Other authorities (*New Statistical Account of Scotland*, 'Perthshire,' p. 454) make the dimensions rather greater. Its surface may be estimated at 15 to 17 square miles, or 10,000 acres. Mr. M'Culloch (*Statist. Account of the British Empire*) gives its surface at 20 square miles, but this we believe to be too great. The banks of the lake are steep and shelving, and the depth of water is supposed to be in some parts not less than 600 feet. It is fed by several mountain streams, and abounds with fish; its surface is at times agitated in a violent and uncommon manner. From the north-eastern or lower end of Loch Tay, the river Tay issues, now under its proper designation, and flows through Strath Tay, or the Vale of Tay. Soon after leaving the loch it is joined by the Lyon; and turning more to the east receives the Tumel, or Tummel, 15 miles below Loch Tay. Both these rivers join the Tay on its left bank. From the junction of the Tumel the Tay flows south-eastward six miles, through several small lakes, receiving the Braan, or Brand, on its right bank; and then, flowing eastward 12 miles more through Strathmore (or the great valley), receives the Isla. From the junction of this stream the Tay turns abruptly to the south-west, south, and south-east, and flows to Perth 12 miles below the junction of the Isla. Its course below Perth is chiefly eastward, and, including the Frith or æstuary of Tay, may be estimated at 26 miles; so that its whole length from the head of the Dochart to the open sea may be estimated at 11[illegible] miles. Just above Perth, the Tay receives the Almond, and several miles below it the Earn, both on the right bank. The Tay is computed to send to the sea a greater volume of water than any other river of Great Britain. Its course above its junction with the Braan is very rapid, but below that point it becomes less so. It is navigable to Perth for vessels of 100 tons, and to Dundee, which is on the shore of the æstuary, for vessels of 500 tons. There is a bar at the mouth, and the navigation is rather difficult, partly from the sand-banks in its channel, and partly from the strength of the tides.

The tributaries of the Tay deserve notice from the system of lakes with which they are connected. The Lyon rises on the western border of the country, and flows east by north through Glen Lyon 28 miles into the Tay. Not far from its source, it flows through Loch Lyon, a small lake about 2 miles long from south-west to north-east. The Tumel issues from Loch Lydoch, a large irregular sheet of water, the greater part of which is included in the border of Argyleshire, adjacent to the wild table-land of Rannoch Moor, 1000 feet above the level of the sea. The surface of Loch Lydoch is perhaps somewhat more than 6 square miles. The Tumel issues from its north-eastern end, and flows eastward about 6 miles into Loch Rannoch, passing in its way through one or two smaller lochs. Loch Rannoch is a long narrow sheet of water, extending 9 miles from west to east, and rarely if ever exceeding a mile in breadth. It abounds with trout of the largest size. Two streams, one flowing into the Tumel, between Lochs Lydoch and Rannoch, and the other into Loch Rannoch itself, serve to convey to the Tumel the superfluous waters of Loch Ericht, another long narrow sheet of water extending in length 14 miles from north to south by one mile in breadth, partly in Inverness-shire and partly in Perthshire. This lake occupies a hollow which cuts transversely the great Grampian chain, while most of the other principal valleys occupied by the streams and lakes of the county run parallel to that chain, and separate it from subordinate lateral ranges, or these ranges from each other. From the eastern extremity of Loch Rannoch, the Tumel flows eastward 10 miles into Loch Tumel, 2 miles long from west to east and half a mile broad, and from thence 12 miles farther east and south into the Tay. Its whole course from its issuing from Loch Lydoch is nearly 40 miles. Between Loch Tumel and the Tay it receives on its left bank the Garry, which has a course of about 30 miles, flows through Loch Garry, a small narrow lake 3 miles long, extending, like Loch Ericht, north and south, and waters Glen Garry, in its course through which it receives on its left bank the streams which water Glen Bruar and Glen Till, and on its right bank the Feachorie, which waters Glen Erochie.

The Braan or Brand, 20 miles long, waters Strath Braan, and serves as an outlet to Lochs Freuchie, Kennard, Skiach, and some others, all small. The Isla, one of the most important feeders of the Tay, belongs chiefly to Forfarshire; only about 14 miles of its course are upon or within the border of Perthshire. Of its tributaries, the Shee or Ericht belongs to Perthshire; it is nearly 30 miles long, and waters Glen Shee; it receives the Airdle, 20 miles long, which rises at the foot of Cairn Gower, in the Ben y Gloe mountains, and waters Strath Airdle. The Almond rises not far from the south-east shore of Loch Tay, and flows about 25 miles east into the Tay. It has no lakes connected with it.

The Earn rises in the western part of the county, and flows east about 5 miles into Loch Earn, which is 7 miles long from east to west, by about one mile broad, and from thence east 33 miles into the Tay below Perth. It waters Strathearn.

The district of Menteith in the south belongs to the basin of the Forth, and is watered by the Teith, which rises just within Argyleshire, and flows 4 or 5 miles, into Loch Catrine or Katrine, a winding and picturesque sheet of water, 8 miles long, from west-north-west to east-south-east, which has become celebrated as the scene of Sir W. Scott's 'Lady of the Lake.' Trout and char are found in it. From the south-east corner of Loch Catrine the Teith flows 9 miles through the Trossachs pass, and at the foot of Ben Venu; it passes through the small Lochs Achray and Vennachar (in which are found trout, salmon, and pike), to Callander, where it is joined by a stream from Loch Voil and Loch Lubnaig, which lie north and north-east of Loch Catrine, and are each about 5 miles long. From Callander the Teith flows south-east 13 miles into the Forth above Stirling; its whole length is about 34 miles. Pearl mussels were formerly fished in this river to a considerable extent. The Allan, a small feeder of the Forth, waters Strath Allan on the north-western and western side of the Ochill Hills; the Devon, another small feeder, waters the valley on the south-eastern side of the same hills; and the Forth itself flows just upon or within the southern boundary of the county for about 30 miles, from the neighbourhood of Ben Lomond to below Stirling. The Allan abounds with trout and some young salmon, and sea-trout are taken occasionally, and various sea-fish are taken in the estuary of the Forth. The Falloch Water, which flows through Glen Falloch into Loch Lomond, is near the south-western border of the county.

The aggregate area of the lakes of Perthshire is estimated at 56 square miles, or 35,000 English acres. The principal of these 'are nothing more than long valleys between the chains of mountains, in which the river at the foot of the mountain, not finding a ready passage for its waters, spreads itself out so as to assume a stagnating form; hence the lakes are usually of great length, but of moderate breadth.' Loch Tay and Loch Ericht are examples of lochs of this kind. When the margin of the lakes exhibits not a steep ascent, but a gentle slope, vegetation is commonly luxuriant, from the length of the days in summer, and the shelter afforded by the low situation. (Forsyth's *Beauties of Scotland.*) Scenes of uncommon beauty are then displayed, such as those which Scott has so accurately and happily described in his 'Lady of the Lake.' The wood round Loch Catrine is made into charcoal and consumed in the Carron iron-works.

There are several falls in the rivers of Perthshire. Those of the Bruar and the Tummel are very picturesque; and the falls and rapids of the Devon, called the Devil's Mill, the Rumbling Bridge, and the Cauldron Linn, are worth a visit.

Soil; Produce; State of Agriculture.—Owing to its mountainous character, a large portion of this county is ill adapted for cultivation. There are very extensive tracts of moor, bog, and moss, though they are progressively diminishing. A large space is occupied either by natural woodlands or by plantations, chiefly the latter, for the ancient forests have been almost entirely destroyed. The plantations have been much extended of late years, and many districts have been covered with them. The late duke of Athol planted above 15,000 acres, of which 2000 acres are in the parish of Blair of Athol, which comprehends the site of the ancient and extensive forest of Athol. In this wild tract the number of red deer is very considerable (said to be 7000); the roes and fallow-deer are also numerous in the plantations. The fox, the wild cat, the badger, the otter, the martin, the polecat, the weasel, and the common and Alpine hare are numerous; and the rabbit, the squirrel, and the rat have lately made their way into this part of the county, where they are becoming troublesome. The eagle builds his nest on the mountain tops, and the kestrel by the falls of the Bruar and in Glen Tilt. Red and black game, the ptarmigan, the plover, and the partridge are abundant.

The natural wood of Athol forest consists chiefly of oak, birch, aspen, and alder. Oak ceases to grow as a natural wood at about 400 feet above the level of the sea, at which the region of the birch seems to commence. There are numerous and tolerably extensive woods of birch to the north of Killikrankie pass. The alder, which abounds on the banks of the Garry, is dwarfish in its growth. Lime, elm, and plane trees are unusually large and numerous in the park of Blair Castle; and the surrounding hills are covered with Scotch fir, spruce, and larch. The Scotch fir was formerly the favourite tree for plantations, but experience has shown that its growth upon light soil and moorish grounds is stunted; the larch is therefore now chosen for dry soils, and the spruce where there is moisture. Oak, ash, birch, beech, and elm are also planted, though not so extensively as the fir tribe.

The cultivated land in the county is estimated at from 230,000 to 360,000 acres, or about one-third of the whole surface. The most valuable tract is the 'Carse of Gowrie,' the district watered by the Isla and its tributaries the Ericht and the Airdle, and comprehending a portion both of Forfarshire and Perthshire. It is a low alluvial district, the finest, in an agricultural point of view, of any in Scotland, and equal to any tract of land in the United Kingdom. The lower part of Strathearn, or the vale of Earn, another low alluvial tract, is scarcely inferior to the Carse of Gowrie. The vale of the Tay, above Perth, and the vales of the Forth and Teith, contain extensive tracts of low alluvium or of gravelly sandy loam. There is little cultivated land in the Highland districts.

Many of the estates are large, but there are also numerous smaller proprietors. The size of the farms varies from 50 to 500 acres; and in the lower districts they are universally held on lease, commonly for fifteen or nineteen years; some of the small Highland occupiers are yearly tenants. The farm buildings in the lowlands are usually substantial, and otherwise excellent, but not so in the Highland tracts. The Carse of Gowrie, Strathearn, and the valleys of the Teith and the Forth yield good wheat and beans; but in the midland districts oats and barley are the principal grain crops. Turnip cultivation has been carried to a considerable extent, and bone-dust has been introduced as manure for this crop; but lime, which is imported at Perth from the Frith of Forth or the north of England, is chiefly employed. The chief article of agricultural produce is however the potato, of which great quantities are yearly shipped for London. The sort generally cultivated is the Perthshire red. This crop forms the chief dependence of the farmer; but it has of late years been very precarious, from defect of vegetation in the sets planted. Some good crops of mangel-wurzel have been raised, and the cultivation of the artificial grasses is improving and extending. (*New Statistical Account,* 'Methven Parish.') The best farmers use a rotation of crops of five or six years, but some keep the land in grass only one year at a time, taking a white crop every alternate year. (*Ibid.,* 'Redgorton Parish.') In the stiff flats of the Carse of Gowrie the rotation is sometimes of seven years. (*Ibid.,* 'Longforgan Parish.') Considerable quantities of apples, pears, and other fruit are raised in the valleys and low grounds, particularly in Gowrie. The use of hedges for enclosures seems to be gaining ground.

There is no breed of cattle peculiar to the county. The stock varies with the varying quality of the pasturage. Many Ayrshire cows for the dairy have been introduced of late years into the lowlands; and some of the best farmers have now a cross-breed from the Teesdale or short-horned and the Ayrshire. (*New Statistical Account,* 'Methven' and 'Redgorton.') The West Highland breed is that commonly fed on the Highland pastures. The number of sheep has been vastly augmented, chiefly by the alteration in the system of farming, and the laying out of sheep-walks in the Highland tracts. The usual breed in these districts is the black-faced Tweedale breed, which has displaced the small white or yellow-faced mountain sheep generally kept of old time; but the Tweedales have of late been partially displaced by the Cheviots. There are some flocks of Leicesters and Southdowns; a few of the former are kept by many of the lowland farmers. The Southdowns chiefly belong to the nobility and other large landed proprietors.

Communications.—The roads of this county have been improved of late years as much as in any county of Scotland. The road from Edinburgh by Queensferry and Dunfermline to Perth enters the county a few miles south of the last-named town. Roads from Dundee, St. Andrews, and from Glasgow, by Stirling, converge at Perth.

From Perth there is a road by Forfar, Brechin, and Stonehaven to Aberdeen; another road follows the valley of the Tay by Dunkeld, and afterwards those of the Tumel and the Garry, through the pass of Killikrankie to Fort Augustus, Inverness, and the Northern Highlands; while a third follows the valley of the Tay and the Dochart into Argyleshire. Three roads lead from Stirling into the Western Highlands through Menteith; one through Aberfoyle to the banks of Loch Lomond, another to Glengyle at the head of Loch Cateran, and another, branching from this, joins the road through the valley the Tay into Argyleshire.

The only navigable rivers are the Tay and the Forth; the latter is navigable up to Stirling for vessels of 70 tons; but its course near that town is so winding that the navigation is little used except for steamers.

A canal has been proposed from the Tay, at Perth, to Crieff and to St. Fillan, at the lower extremity of Loch Earn.

Divisions, Towns, and other Localities.—Pertnshire was formerly divided into the six districts of Gowrie (east), Perth (south-east), Stormont (central), Strathearn (central), Menteith (south), Breadalbane or Braidalbin (west and central), Balquhidder (south-west), and Rannoch (north-west), each of which was a distinct Stewartry, that is, was in the jurisdiction of a distinct sheriff or steward; but the Act of 1748, abolishing hereditary jurisdictions, put an end to the legal existence of these divisions, though the names are still popularly applied to the respective districts, or are retained in the titles of the nobility. To these may be added the Highland district of Athol or Athole or Atholl, in the northern part of the county.

Perth, the capital, and Culross, are both royal burghs; Auchterarder, Abernethy, and Dunblane were formerly royal burghs; Dunkeld, Crieff, Longforgan, Cupar, and Alyth are burghs of barony; the other principal towns or villages are Auchtergaven, Blair-Gowrie, Callander, Errol, Doune, Kinnoul, Methven, Muthill, Scone, and Kincardine in Tulliallan parish.

Perth is on the right bank of the Tay. It is a place of great antiquity. The name is supposed to be derived from the Celtic Bhar-tatha, 'the height of Tay,' whence Bertha (the name given to the town in many antient writings) and Perth. Some have supposed, but apparently through misconception, that Bertha and Perth were different places. The town is said by some to have had a Roman origin, but this is not clear, though two Roman stations, the Orrea of Ptolemy and Richard of Cirencester, and the Ad Taum or Tavum of Richard, were in the neighbourhood. In the *New Statistical Account of Scotland* it is proposed to identify Perth with the Victoria of Richard, which others fix at Dealgin Ross on the Earn. Perth was for a time in the hands of the Picts; it was a burgh in A.D. 1106, and down to the death of James I. (A.D. 1437), was regarded as the capital of Scotland. It was the seat of a considerable trade, which the burgesses carried on in their own vessels with the Hanse Towns; and many Flemings and Germans settled here. The kings of Scotland unwisely subjected these foreigners to many restrictions.

In the war of Edward I. in Scotland, Perth was taken by that king immediately after the defeat of Wallace at Falkirk (A.D. 1298). He restored and strengthened the fortifications, and the town remained in the hands of the English, and was frequently the residence of the kings' deputies till A.D. 1311, when it was surprised and taken by Robert Bruce, and the fortifications were levelled with the ground. Perth was taken after the battle of Duplin, fought a short distance south of the town, on the Earn (A.D. 1332), by Edward Baliol, who repaired the fortifications, in which he was soon besieged by the Scots, who hoped to reduce him by famine. A victory gained by the English ships stationed at the mouth of the Tay to support him, compelled them to give over the enterprise. The town was soon after taken by the pasty of David Bruce, but subsequently reverted to the hands of Baliol and his party, and Edward III. of England was twice at Perth in his expeditions into Scotland (A.D. 1335-36). The Scots in the interest of David Bruce, under the command of Robert, steward of Scotland, afterwards King Robert II., took Perth (A.D. 1339) and entirely crushed the party of Baliol. Many years afterwards (A.D. 1396) the judicial combat took place between two parties of thirty men each from two clans of unascertained name, which has furnished a striking incident in Sir Walter t's 'Fair Maid of Perth.' (*Chronicles of the Canongate. Second Series.*) In 1425, James I., during the sitting of a parliament at Perth, arrested his cousin Murdoch, duke of Albany, ex-regent, and several of his family and partisans, including some of the most powerful barons in Scotland. Albany, two of his sons, and his father-in-law, the earl of Lennox, were executed. In 1437, James himself was assassinated in the Dominican monastery at Perth, by conspirators whom his unsparing reforms had provoked. After this event, Edinburgh became the seat of government, though Perth continued to be nominally the capital of the kingdom till A.D. 1482. In A.D. 1512, and in A.D. 1585-87, Perth was visited by the plague. Before the Reformation, there were several religious houses at Perth.

In August, 1600, Perth was the scene of that mysterious incident the Gowrie conspiracy to assassinate James VI. [James I. of England.] In 1644 it was taken by Montrose, after his victory at Tippermuir, and in 1651 was again taken by capitulation by Cromwell, after the defeat of the royalists at Burntisland. He built a fort near the town to overawe it, which fort, after the Restoration, Charles II. gave to the town. Having fallen into a dilapidated state, the materials were sold, and it was entirely demolished. The site is now levelled, and all traces of it are obliterated. Perth was occupied by the insurgent Highlanders in the rebellions of 1715 and 1745.

The town is on the right bank of the river Tay, and is connected by a handsome bridge of nine arches, 880 feet long, over that river with the Bridge-end of Kinnoul, which (Bridge-end) is included in the boundary of the modern parliamentary burgh. The streets of Perth are for the most part straight and conveniently laid out, well lighted with gas, and clean, with good side pavements. The houses are substantial, and those in the environs of the town, which are of later erection than those in the more central parts, are built of freestone, and present a handsome appearance. North and south of the town are two large public greens, called respectively the 'North Inch' and the 'South Inch.' The North Inch contains the race-course, and the South Inch is surrounded by stately trees and elegant villas. The principal public building is the church of St. John. The square tower is of antient but unascertained date, and is possibly part of the original church erected on this site; it has been surmounted at a later period by a pyramidal spire of wood covered with lead, and is furnished with bells and chimes. The body of the church has undergone considerable alteration, and is now divided into three places of worship, appropriated to three distinct parishes. There are three other Presbyterian churches of modern erection, one of them especially designed for the Highlanders of the town and its neighbourhood. There are sittings in these churches for above 6000 persons. In addition there are fourteen dissenting places of worship of various denominations, containing accommodation for nearly 9000 persons. A handsome building containing the county-hall, courts of justice, and other apartments for county business, of Grecian architecture, faces the Tay. Behind it is the new city and county gaol for felons, misdemeanants, and debtors. The other public buildings are those of the Academy, a neat theatre, a lunatic asylum (one of the most perfect establishments of the kind in Scotland), a range of barracks, and another of government storehouses, formerly used as a depôt for French prisoners; Marshall's monument (a building erected to commemorate the services of a late lord provost), containing the public library and the museum of the Perthshire Antiquarian Society; the gas-works, and the water-works. The range of barracks and storehouses is now in course of being converted into a prison, in which an improved system of discipline will be adopted, with a view to the reformation of the prisoners, and to the establishment of a model for other places of confinement for offenders. The market for flesh, vegetables, and butter is held near St. John's church; the fish-market on the bank of the river below the bridge. The council-hall for the town is near the fish-market.

The population of Perth, in 1831, was 20,016. The number of inhabited houses was 2049; of families, 4936; of whom only 53 were returned as engaged in agriculture. The ordinary population was estimated to be at least 1200 more than the Return, many of the wealthy being absent at sea-bathing places, and many of the poor engaged in field-labour or fishing; and the number of inhabitants has increased since the Return was made. The manufactures of the place consist principally of coloured cottons, especially for umbrellas. A great quantity of handkerchiefs, striped and checked ginghams, shawls, scarfs, and trimmings are also made. About 1500 persons are employed in weaving. A large flax and tow-yarn mill employs above 100 hands; a large bleaching and cotton-printing work at Tulloch, in the neighbourhood of Perth, employs 250; and there are other bleaching and print fields, besides three considerable iron-foundries, distilleries, breweries, and corn-mills. The salmon-fishery in the Tay is valuable. The chief imports are coal, lime, salt, and manure, brought coastwise; and from foreign parts (chiefly from the Baltic), timber, flax, linseed, clover-seed, corn, bark, hides, smalt, madder, &c. The exports are chiefly potatoes, sent to London, the value of which in Perth may be estimated at 65,000*l.* per annum; the value in London (freight and other charges being then included) above 100,000*l.*; the other articles of export are corn, timber, and slates. Nearly 90 vessels (with nearly 5500 aggregate tonnage) belong to Perth; no ship is registered at more than 100 tons, but vessels of twice that size have been built at Perth. Great exertions have been made within the last few years to improve the harbour. There are two weekly markets, the principal one on Friday, and there are five yearly fairs.

By the Burgh *Reform* Act (3 & 4 Will. IV., c. 76), the town was divided into four wards. The town-council consists of a lord provost (who is also sheriff and coroner), a dean of guild, four bailies, a treasurer, and twelve other councillors. A burgh court is held weekly, over which one of the bailies presides. The property of the burgh is estimated at nearly 70,000*l.*, the debts at nearly 20,000*l.* There are seven incorporated trades. Before the Parliamentary Reform Act, Perth returned one member in conjunction with Dundee, Forfar, Cupar of Fife, and St. Andrews. It now sends one by itself. The parliamentary bounds do not comprehend the whole area of the burgh. The police of the city is regulated by a local act, but it is imperfect. The justiciary court for the county and the sheriff's court for the division are held at Perth.

Perth has several educational and literary institutions. The 'academy' is an endowed institution, comprehending a mathematical and scientific school, a grammar school, a school of modern languages, two English schools, a writing school, and a drawing school. The reputation of the academy is very considerable. There were, in March, 1837, six other endowed schools, and twenty-two unendowed. The state of instruction among the poor however is very low; a local subscription was in consequence opened in 1834, and aided by grants from the lords of the Treasury and from the burgh authorities, for the purpose of erecting schools for city children. There are a public circulating library of from 5000 to 6000 volumes, a public news-room, and five private circulating libraries. There are four weekly news-papers printed in the town. A Literary and Antiquarian Society was established in 1784, which still flourishes, and has a collection of books, manuscripts, coins, objects of natural history, &c.

The charitable institutions include an hospital or almshouse, now disused and let, the rent being distributed in alms; an infirmary, capable of receiving above 20 patients; a dispensary, and several almsgiving societies. There are savings' banks and benefit societies. The poor are further relieved by a parochial assessment, by collections at the places of worship, and by gifts from the funds of the incorporated trades. The amount distributed in alms is very considerable, and the number of receivers tolerably large.

Culross is on the northern shore of the Frith of Forth, 23 miles from Edinburgh, and 6 from Dunfermline, in a detached part of the county. It had antiently an abbey of the Cistercian order. It was erected into a royal burgh by James VI. (James I. of England), A.D. 1588, at which time it was very prosperous, owing to some coal-works, the produce of which was exported to Holland. These works have been long discontinued. The manufacture of 'girdles' or iron plates, for baking oaten cakes, was formerly very flourishing, but is now discontinued. Culross has no market, and little trade is carried on. Dunfermline is the mart for the produce. About seventy persons are employed in weaving cotton or linen. There is a small pier for fishing and passage boats, which latter cross the Forth to Borrowstowness. The population of the parish, in 1831, was 1488, of whom less than half were in the town. The church, which antiently formed part of the conventual church of the abbey, is a cruciform building, with a massive western tower, in a commanding situation in the higher part of the town. There are some ruins of the former parish church in the parish burial-ground, which is still in use. The parish is well provided with the means of education, and there is a parish library of 200 volumes, another library, and a benefit society for funerals. The corporation was left untouched by the Scotch Burgh *Reform* Act (3 & 4 Will. IV., cap. 76). The council consists of 19 members, including a provost, two bailies, and a treasurer. The magistrates have rarely occasion to exercise their jurisdiction. The town-house is an old building, two rooms of which are appropriated as a prison, but seldom used. Culross unites with Inverkeithing, Dunfermline, Queensferry, and Stirling to return one member to parliament.

Auchterarder is described elsewhere. [AUCHTERARDER.] It was in this parish that the contest, now carried on in Scotland, between the civil and ecclesiastical courts, originated.

Abernethy is at the junction of the Earn with the Tay, 7 miles south-east of Perth. It was antiently the capital of the Picts, and the seat of a bishop, who was metropolitan, if not of all Scotland, at least of that part which was held by the Picts. The see was afterwards removed to St. Andrews, and the church was made collegiate. One relic of its Pictish greatness remains; a round tower 75 feet high and 48 feet in circumference at the base, but diminishing toward the top, built of hewn stone. The thickness of the wall is about 3½ feet. It serves as a belfry and clock tower to the church, which stands near and is a modern building. Abernethy is a dirty irregular place, with a population for the whole parish (which extends into Fifeshire) of 1776 inhabitants; the principal branch of industry is linen weaving.

Dumblane, or Dunblane, is on the road from Perth to Stirling and Glasgow, on the left bank of the Allan, over which there is a bridge. It was antiently one of the seats of the Culdees (a religious order diffused through Scotland and Ireland), and subsequently became the seat of a bishopric, which included parts of Perthshire and Stirlingshire. The town consists of a street of old-fashioned houses and a few lanes. The former cathedral, the choir of which is now used as the parish church, is a large Gothic building on an eminence. All parts, except the choir, are dilapidated, though in better preservation than most of the old ecclesiastical buildings of Scotland. A modern steeple, 128 feet high, has been erected adjacent to it. There is a dissenting meeting-house. The population in 1831 was 3228, above one-fourth agricultural. About 200 men are employed in manufactures. The court of the sheriff-substitute of the division is held here. The small town-house, comprehending two rooms, is used as prison. There is a weekly market, and there are four yearly cattle-fairs. A mineral spring about two miles distant attracts many visitors. There is a public library of 1400 volumes, the foundation of which was a bequest of books by the excellent Leighton (afterwards archbishop of Glasgow), who held for a time the see of Dunblane.

Dunkeld is on the left bank of the Tay, 15 miles north of Perth. It lies in a deep hollow under the brow of lofty wooded hills. The houses are generally old and of mean appearance; and there are no manufactures, except of leather and linen. The town derives benefit from visitors, who are attracted to it by the beauty of its situation and its convenience as the point of entrance upon the Highlands. There was an antient monastery of Culdees here, and in 1127 it was made the seat of a bishopric, which in the early part of the sixteenth century was held by Gawin Douglas. The cathedral, which was partly of Norman, partly of later architecture, is in ruins, except the choir, which serves as the parish church. There is a fine bridge of seven arches over the Tay, and near the town is a seat with beautiful grounds belonging to the Duke of Athol. There is a weekly market, and there are several yearly fairs. The population in 1831 was 1471. Dunkeld is a burgh of barony, of which the Duke of Athol is superior.

Crieff is beautifully situated near the north or left bank of the Earn, 17 miles west of Perth. It was burned by the Highlanders in 1715, and was only saved in 1745 from a similar fate by the interference of the Duke of Perth. The town is thriving. There are two modern churches; that of latest erection is in a commanding situation, and is the finest building in the town. There are three places of worship for Seceders and one for Catholics. There are a nu-sons' hall and a weavers' hall. The population of the parish in 1831 was 4786; of whom about four-fifths were in the town. There are nearly 500 handloom weavers, who make cotton-checks and handkerchiefs, linens and worsted stuffs, blankets, plaids, and shawls. There are tan-yards, flour-mills, malthouses, distilleries, two cotton-mills, an oil and a paper mill, and bleach-fields. Tambour-working and other similar occupations are pursued by the females. There are quarries of inferior sandstone in the neighbourhood. There are a weekly market and nine yearly fairs. Crieff is a burgh of barony; a justice of the peace court (or petty session) is held every month for small debts and minor offences; there is also a committee to manage the affairs of the town, but the police is very deficient; and petty thefts, assaults, and other similar offences are frequent. There is a prison, or lock-up-house of one cell. There are fifteen schools, four of them Sunday-evening schools, and a Sunday-evening class for the religious instruction of young men and women.

Longforgan is a long straggling place, 18 miles from Perth on the road to Dundee. It had a population in 1831 of 1638 for the whole parish; of whom about 150 (men and women) were engaged in weaving sheeting, sacking, and linens, and about 50 women and children in winding or otherwise preparing the yarns for the loom. There are quarries of excellent freestone in the parish, in which about 60 men are employed. There are a large church, six schools, a library, and a savings' bank. There are three yearly fairs. Near the town are the ruins of an antient chapel belonging to the Cistertian monastery of Cupar Angus, and the noble baronial seat of Castle Huntly.

Cupar of Angus is partly in Forfarshire, but chiefly in Perthshire near the right bank of the Isla. Near the town are the traces of a Roman camp and the ruins of a rich monastery. The town is neatly built, with clean and well lighted streets; there are a church, an Episcopal chapel, two Dissenting Presbyterian meeting-houses, a town-house, and small gaol, or lock-up-house of one cell. Linen-weaving, tanning, and bleaching are carried on; there are a weekly market and four or five yearly fairs. The population in 1831 was 2615. Alyth is described elsewhere. [ALYTH.] Auchtergaven had in 1831 a population of 3417, a great number of whom were employed in the cotton-works at Stanley, a village on the Tay, partly in this parish. There are quarries of freestone in the parish and a small salmon-fishery. Malting, distilling, and linen-weaving are carried on. There is a parish church, besides a handsome chapel-of-ease, erected by the proprietors of the Stanley cotton-works; a school is also maintained by them. A yearly fair is held at Auchtergaven. Blairgowrie is described elsewhere. [BLAIRGOWRIE.] Callander, on the Teith at the junction of the stream from Loch Lubnaig, consists of a wide and clean street, with substantial freestone houses roofed with slate. The population of the parish, which is very large, was, in 1831, 1909. The village is resorted to by visitors to Loch Catrine and the romantic scenery around. There are a parish church, several inns, three schools, and three libraries. There are several fairs in the year.

Errol is a small and mean place, but in a beautiful situation near the Frith of Tay. The church is a modern cruciform building in the Norman style, with a lofty square tower and pinnacles. The population of the parish in 1831 was 2992, about two-fifths of them resident in the village. Stone-quarries are worked, and salmon and smelt fisheries carried on; but the linen-manufacture is the chief branch of industry: it employs 200 men and 100 women as weavers, beside winders and other assistants. Doune, on the banks of the Teith, eight miles from Stirling, is remarkable for a handsome Gothic church and tower, of modern erection; a fine old bridge over the Teith; and the ruins of Doune Castle, an antient fortress of great strength and extent. There are extensive cotton-works at Deanston, close to the village, and several cattle-fairs are held in the course of the year. Doune is in Kilmadock parish, the population of which in 1831 was 3752. Bridge-end of Kinnoul is a suburb of Perth. Methven is a manufacturing village, a few miles west of Perth (pop. of parish, in 1831, 2714) with a commodious parish church, three good schools, a library of 1100 volumes, a friendly or benefit society, and a savings' bank. Muthill is a clean village, beautifully situated in Strathearn, a short distance from Crieff southward, with a population of 1100 or 1200 (or for the whole parish, in 1831, of 3297). There are a parish church at Nuthill, and a chapel-of-ease at Ardoch; an Episcopalian chapel, a Secession meeting-house, nine schools, a library and reading-rooms, at Nuthill; another library at Braco village near Ardoch, and a library for ministers and students at Innerpeffary, all in the parish; a savings' bank, and a Bible and Missionary Society. There are three considerable distilleries, which make yearly 100,000 gallons of whiskey. Scone, near the right bank of the Tay, rather more than a mile north of Perth, is memorable for its palace, the antient residence of the Scottish kings and the place of their coronation. It had also an abbey of the regular canons of St. Augustin. The palace and the abbey (except one aisle) have both disappeared: a modern house, the seat of the earl of Mansfield, occupies the site of the former. The village of Scone is neat and regularly built. Population of the parish in 1831, 2268. Kincardine is a thriving port on the Tay, with a good quay and harbour. There are sail-lofts and rope-walks, and brewing and distilling are carried on. Many of the traders are shipowners, and several vessels have been built. There were formerly salt-pans near the town, but they have been given up. There is a yearly fair. The parish church is at Tulliallan, near Kincardine, but there is a Dissenting meeting-house in the town. Population of the parish in 1831, 3550.

Industry.—The cotton-manufacture has been already noticed. Several towns and villages participate in the linen manufacture, of which Dundee is the centre. Wo[illegible] and some silks are also woven, the latter at Perth. From 3000 to 3500 men were employed as weavers in these branches in 1831, beside females and children, who (in the cotton-works especially) are very numerous. Above [illegible] men are employed in other branches of these manufactures, spinning, bleaching, printing, &c., or in other manufactures. From 250 to 300 men are employed in stone, lime, and slate quarries; 50 or more in coal-pits, chiefly in Tull[illegible] and Fossoway parishes, on the Fifeshire border; and [illegible] men in an ironstone-mine, also in Fossoway parish. The salmon fishery on the Tay employs 100 men or more, and several men are engaged in the distillation of whiskey at different places.

Ecclesiastical, Legal, and Parliamentary Arrangements.—The number of parishes wholly or partly in this county was in 1818, 80 (see Playfair's *Description of Scotland*); but some of these have been subsequently divided for ecclesiastical purposes: the present number is probably nearly [illegible]. They are included in the presbyteries of Perth, Dunblane, Dunkeld, Auchterarder, Meigle, Dundee, and Dunfermline. The presbyteries of Perth, Auchterarder, Dunkeld, and Dunblane, are in the synod of Perth; those of Meigle and Dundee, in the synod of Angus and Mearns; that of Dunfermline in the synod of Fife. In antient times the county was chiefly if not wholly included in the dioceses of Dunblane and Dunkeld.

The county is divided into two districts, each under a sheriff substitute; and is subdivided into ten smaller districts, each under the jurisdiction of a justice of the peace court. There are eight prisons, two at Perth (one of them a small house of correction), and one each at Blairgowrie, Dunblane, Crieff, Dunkeld, Kincardine, and Culross; several of these are very small and bad. Crime is not frequent in the county, and is rather decreasing. The most frequent offences are assaults, chiefly made under the excitement of spirituous liquors. Drunkenness is believed to have increased. The police is very good at Perth, and tolerable in other parts of the county. Mendicants are numerous, but they are chiefly vagrants. Education is much improved, and is now tolerably general in the rural districts; but the means of instruction are very deficiently supplied at Perth, though steps have been lately taken to supply the deficiency. (*Inspectors of Prisons' Second Report*, 1837.) The greatest number of scholars of all classes at the daily schools in Perthshire between Michaelmas, [illegible], and Ladyday, 1834, was estimated at 18,862. (*Education Returns, Scotland*, 1834.)

The county returns one member to parliament; but the parishes of Tulliallan, Culross, Muckhart, Logie, and Fossoway have been annexed for parliamentary purposes to the shires of Kinross and Clackmannan, which in conjunction return one member. Perth returns one member for itself; and Culross unites with Inverkeithing, Dunfermline, Queensferry, and Stirling, to return another.

Historical Events; Antiquities.—In the obscurity that hangs over the geography of antient Caledonia, little that is certain can be advanced as to the earliest inhabitants of Perthshire. The eastern side was occupied by the [illegible] nicones (Οὐενίκωνες) of Ptolemy, whom we may probably regard as identical with the Vecturiones or Venturiones of Richard, and the Vecturiones of Ammianus Marcellinus. Both Ptolemy and Richard agree in assigning to this people the town Orrea (Ὄρρεα), which is supposed to have been at the junction of the Tay and the Almond, or perhaps on the opposite (eastern) bank of the river. There are slight traces of a station at the junction of the Almond and Tay, though in great measure destroyed by a variation in the channel of the Almond; and there are traces of a camp at Grassy Walls, on the opposite side of the river, a little farther to the northward. The country south of the Tay was inhabited first by the Damnii, afterwards by the Horestii, or Horesti, who are mentioned by Tacitus. (*Agric.*, c. 38.) The highlands of Perthshire were probably occupied by the Damnii Albani, 'a people little known,' says Richard, 'being wholly secluded among lakes and mountains.'

The Tay, under the form Tavus, is mentioned by Tacitus (*Agric.*, c. 22), by Ptolemy, who writes it Ταοῦα, and by Richard. The Earn appears in Richard under the name of Hierna. If we may trust the authority of the last, the whole county, except perhaps the western boundary, was comprehended in what was termed the province of Vespasiana, over which the Romans possessed only a very brief and precarious sway.

A Roman road crossed the western side of the county from the neighbourhood of Stirling to Orrea, near Perth, at or near which it probably divided into two branches, one directed toward the coast, the other crossing the Grampians (the Grampius Mons of the Roman historians and geographers), towards the shore of Murray Frith. There were several Roman stations in Perthshire. Alauna (Ἀλαῦνα) was probably at Kier, just within the county, near Stirling. The name appears to be equivalent to the Welsh 'Caer,' which usually marks a Roman post or town. The next station was Lindum (Λίνδον), now Ardoch, in Strathallan, one of the strongest and most perfect Roman works in the island. [ARDOCH.] Next to this was Victoria, probably Dealgin Ross, in Strathearn, where are some remains of Roman works, apparently never completed. This station was established and named by Agricola to commemorate his great victory over the Caledonians under Galgacus. The next station was Ad Hiernam, which may be fixed at Strageath, on the Earn, or Hierna. There are the remains of a Roman post, which has evidently been of great strength. Orrea has been noticed. The position of the Ad Tavum of Richard is disputed. Mr. Hatchard, in his edition of Richard, places it at Invergowrie, on the Tay, just above Dundee, in Forfarshire; General Roy, at Burgh Tay, below Dundee; and the Map of Antient Britain, published by the Society for the Diffusion of Useful Knowledge, in the neighbourhood of Perth. There are the remains of a Roman camp at Invergowrie. Ad Tavum was on the road from Orrea to the coast. The In Medio of Richard was probably at Inchtuthill, on the Tay, above the junction of the Isla, where are some remarkable Roman works, or perhaps at Cupar Angus. There are the remains of a Roman camp at Fortingale, in Glen Lyon. The prætorium is still complete. There are the piers of a bridge over the Tay, close to the junction of the Almond, where the situation of Orrea may be fixed.

Alauna, Lindum, and Victoria, according to Ptolemy, belonged to the Damnii, who inhabited for the most part within the ramparts of Agricola and Antoninus. They appear to have withdrawn from that part of the territory which lay beyond the rampart, and which was subsequently appropriated by the Horestii, who came from Fifeshire.

This county was the scene of hostility perhaps in the third campaign of Agricola (A.D. 80), at any rate in the sixth and seventh (A.D. 83, 84). The attack made by the Caledonians on the camp of the ninth legion, in the sixth campaign, was probably at Dealgin Ross. Severus must have crossed Perthshire in his war against the Caledonians (A.D. 206, 207).

There are some remains of a large Druidical circle and several antient circular forts in the Highland parish of Fortingale, or Fortingal. The age and origin of the forts is not known. Remains of circles, cairns, and other Druidical remains are found in the parishes of Kirk-Michael, Blair Athol, Cargill, &c. There is a remarkable fort, partially vitrified, at Alyth.

At the downfal of the Roman empire, Perthshire was occupied by the Picts, who had Abernethy for their capital; it afterwards came into the hands of the Scots. In the latter part of the tenth century, the Danes arrived at the mouth of the Esk with a large fleet, and landing, marched to the Tay. They were entirely routed by the Scottish king, Kenneth III., at Luncarty, near Perth, probably in A.D. 990. Dunsinnan or Dunsinane Hill, in Collace parish, between Perth and Cupar Angus, was the stronghold of Macbeth, where he was defeated by the English allies of his competitor Malcolm (A.D. 1054). The importance of Perth, and its rank as capital of the kingdom, made this shire the scene of many contests. In 1306 Robert Bruce was defeated at Methven, near Perth, by Aymer de Valence, earl of Pembroke, and the English army. In 1332 Edward Baliol, competitor of the minor King David Bruce, at the head of an invading force, chiefly of English, defeated the Scots under the regent, the earl of Mar, at Dupplin Moor, on the Earn. He took Perth, where he maintained himself for some time, until his party was finally crushed by the partisans of David Bruce.

In the campaign of Montrose (A.D. 1644) this county was the earliest scene of action. At the head of 1100 ill-armed Irish foot and 1300 Highlanders, Montrose defeated 5000 Covenanters, under Lord Elcho, at Tippermuir near Perth, with the loss to them of 2000 killed. The Scottish parliament, which supported the claim of Charles II. to the crown, assembled in 1650 at Perth; and on new-year's day, 1651, Charles II. was crowned with great solemnity at Scone. In the same year Perth was taken by Cromwell, and the royalist party crushed.

In the struggle at the Revolution, A.D. 1689, Perth was taken by surprise by Viscount Dundee, but he soon abandoned the town and retired into the Highlands. On the 17th of July, at the head of about 2200 men, including 300 Irish, he defeated a more numerous government army under General Mackay, with the loss of 2000 men; but the death of Dundee, who fell early in the action, prevented any beneficial result of the victory. The Highlanders were repulsed in an attack on Dunkeld, where a Cameronian regiment was posted, and soon afterwards dispersed; and the war came to an end. In the rebellion of 1715-16, a battle was fought on Sheriff Muir, near Dunblane, between the Highlanders, to the number of 10,000, under the earl of Mar, and 4000 government troops, under the duke of Argyle. The battle was drawn; but the government reaped from it the advantage of victory. The Pretender was for a short time at Scone during the insurrection. In the second Jacobite rebellion, the young Pretender was at Perth in 1745, and the duke of Cumberland in 1746. A body of government troops was blockaded in the castle of Blair-Athol by the insurgents under Lord George Murray (March and April, 1746), and relieved, when reduced to extremity, by a royalist detachment from Dunkeld.

The antiquities of the county consist chiefly of the remains of Dunblane and Dunkeld cathedrals; some other scanty ecclesiastical remains; some ruins of antient castles at Moulin, Doune, Kincardine, Kincleven, and Drummond Castle near Muthil; and some hill forts, cairns, and Druidical stones. Blair-Athol Castle has been modernised, and is the present seat of the duke of Athol.

(*New Statistical Account of Scotland*; *Playfair's Description of Scotland*; Chambers's *Gazetteer of Scotland*; Sir W. Scott's *History of Scotland*, in *Lardner's Cyclopædia*; *Parliamentary Papers*.)

PE'RTINAX, PU'BLIUS HE'LVIUS, born about A.D. 126, at Villa Martis, near Alba Pompeia, now Alba in Piedmont, on the banks of the Tanarus, was the son of a freedman who dealt in charcoal, an important article of fuel in Italy even at the present day. His father gave him a good education, placing him under the tuition of Sulpicius Apollinaris, a celebrated grammarian, who is repeatedly quoted by Aulus Gellius. Pertinax became a proficient in the Greek and Roman languages; and after the death of his master, he taught grammar himself. But being dissatisfied with the small profits of his profession, he entered the army; and being assisted by the interest of Lollianus Avitus, a man of a consular family and his father's patronus, he was promoted to a command. He was sent to Syria at the head of a cohort, and served with distinction against the Parthians, under L. Verus, the colleague of Marcus Aurelius. He was afterwards sent to Britain, where he remained for some time. Subsequently he served in Mœsia, Germany, and Dacia; but upon some suspicion of his fidelity, he was recalled by Marcus Aurelius. Having cleared himself, he was made prætor and commander of the first legion, and obtained the rank of senator. Being sent to Rhætia and Noricum, he drove away the hostile German tribes. His next promotion was to the consulate, and he publicly received the praise of Marcus in the senate and in the camp for his distinguished services. In Syria he assisted in repressing the revolt of Avitus Cassius. He was next removed to the command of the legions on the Danube, and was made governor of Mœsia and Dacia, and afterwards returned to Syria as governor, where he remained till the death of Marcus. Capitolinus says that his conduct was irreprehensible till the time of his Syrian government, when he enriched himself, and his conduct became the subject of popular censure. On his return to Rome, he was banished by Perennis, the favourite of Commodus, to his native country, Liguria. Here he adorned Villa Martis with sumptuous buildings, in the midst of which however he left his humble paternal cottage untouched. He remained three years in Liguria. After the death of Perennis, Commodus commissioned him to proceed to Britain, where the licentiousness of the troops had degenerated into mutiny. On his arrival, the soldiers wished to salute him emperor, and were with difficulty prevented by Pertinax, who seems to have found the discipline of the legions in that remote part of the empire in a most deplorable state. One of the legions revolted against him; and in trying to repress it, he was wounded, and left among the dead. On his recovery, he punished the mutineers, and solicited the emperor for his recall, as his attempts at restoring discipline had rendered him obnoxious to the army. He was then sent proconsul to Africa, and was afterwards made præfect of Rome, in which office he showed much temperance and humanity. After the murder of Commodus, two of the conspirators, Lætus and Electus, went to Pertinax and offered him the empire, which Pertinax at first refused, but afterwards accepted, and was proclaimed emperor by the senate in the night previous to the first of January, A.D. 193. In the speech which Pertinax delivered on the occasion, he said something complimentary to Lætus, to whom he owed the empire, on which Q. Sosius Falco, one of the two consuls, observed, that it was easy to foresee what kind of an emperor he would make, if he allowed the ministers of the atrocities of Commodus to retain their places. Pertinax mildly replied, 'You are but a young consul, and do not yet know the necessity of forgiving. These men have obeyed the orders of their master Commodus, but they did it reluctantly, as they have shown whenever they had an opportunity.' He then repaired to the imperial palace, where he gave a banquet to the magistrates and principal senators, according to the antient custom. The historian Dion Cassius was among the guests. Pertinax recalled those who had been exiled for treason under Commodus, and cleared from obloquy the memory of those who had been unjustly put to death. But his attempts to restore discipline in the army alienated the affections of the soldiers, who had been accustomed to licence under the reign of Commodus. As he found the treasury empty, he sold the statues, the plate, and all the valuable objects amassed by Commodus, and even his concubines. By this means he collected money to pay the Prætorians, and to make the usual gifts to the people of Rome. He publicly declared that he would receive no legacies or inheritance from any one, and he took away several taxes and tolls which had been imposed by Commodus. Pertinax was cherished by the senate and the people; but the turbulent Prætorians, secretly encouraged by the traitor Lætus, conspired against the new emperor. After offering the empire to several persons, they went to the palace, three hundred in number. The friends of Pertinax urged him to conceal himself till the storm had passed; but the emperor said that such conduct would be unworthy of his rank; and he appeared before the mutineers, and calmly remonstrated with them upon the guilt of their attempt. He was making an impression upon them, when one of the soldiers, a German by birth, threw his spear at him and wounded him in the breast. Pertinax then covered his face, and, praying the gods to avenge his murder, was finished by the other soldiers. Electus alone defended him as long as he could, and was killed with him. The soldiers cut off the head of Pertinax and carried it into their camp, and then put the empire to auction, offering it to the highest bidder. [DIDIUS, JULIANUS.] Pertinax was sixty-seven years of age, and had reigned eighty-seven days.
